All this leaves our knowledge of the action of the *cortex* of the capsules very much in the position which it occupied 40 years ago—indeed, one may even say in the position it occupied in the time of Montesquieu. It is certain that we cannot as yet allocate any definite function to the cortical cells. Nevertheless, we cannot doubt that they possess a function, and an important one. Of the two parts of the gland, the cortical is the most constant in the vertebrate sub-kingdom. It is relatively best developed in late fœtal and in early extra-uterine life when growth and differentiation are proceeding rapidly; it is present during the whole of life, and there is no evidence that it undergoes any atrophic changes with age. It is impossible even to say that it is functionally related to the medulla, although its close topographical connexions with that structure in most animals—and the closer the higher we proceed in the scale of organisation—seem to betoken some functional nexus. A relationship to the development of the generative organs has been suggested on the ground that in cases of precocious sexuality the suprarenal capsules—presumably the cortex—have been found hypertrophied (Wooley, 1902; Bulloch and Sequeira, 1905). A resemblance between the cells of the cortex and those of the corpus luteum of the ovary has been frequently pointed out, but this may be merely superficial. It has been recently more particularly insisted upon by Kinlon (1906). It has also been suggested that the suprarenal cortex has antidotal properties for certain poisons, such as snake venom (Myers, 1907).

Biedl states that he has been able to remove the cortex, leaving the medulla intact, and that the operation was followed by the death of the animals; but I think the experience of most people would lead them to believe such a separation to be impossible. And, as I have already stated, Vincent did not find removal of the inter-renal body in the eel—which undoubtedly represents in that animal the cortex of the mammalian organ—to be fatal. That the cortical cells are internally secreting structures is pointed to by their epithelium-like appearance and the richness of the arterial blood-supply of this part of the organ. Ciaccio (1906) has described in the cells what he regards as evidences of secretory activity, such as are met with in the cells of ordinary secreting glands. But even without direct evidence it is difficult not to believe that the cortical cells produce an internal secretion, which is either taken up by the blood or is otherwise conveyed away from the cell columns. It is open to us to suppose that these may initiate the preparation of the internal secretion (adrenin) of the medulla, or that they may prepare an enzyme which completes the formation of that substance. The experiments of Abelous, Soulié, and Tougan (1905) are confirmatory of this suggestion but do not carry conviction. On the other hand, there are both anatomical and pathological reasons for believing that the internal secretion of the cortex is independent of that of the medulla and produces quite different effects in the organism.

According to Della Vida (1904) cytotoxic serums prepared from the two parts of the gland are only toxic for their respective parts. That the suprarenals are related in some way to metabolic changes in the tissues and organs there can be little doubt. This is indicated by the symptoms of Addison's disease. Some of these symptoms can be referred to the absence of medullary secretion. But others, such as the extreme wasting (when not due to general tuberculosis) and the malnutrition which is expressed in the abnormal pigmentation of the skin and mucous membrane, are not readily referred to the medulla, and are probably the result of disease of the cortex. In assuming that the cortex of the organ subserves through its internal secretion certain functions connected with metabolism we have an analogy with what is known regarding the pituitary body. In this, again, we find an instance of a small ductless gland, partly epithelio-nervous, and partly purely epithelial in structure and origin, the two parts having different functions, although bound up together into a single organ. Of the two parts, the nervous part, as in the suprarenals, produces a substance or substances such as it is now customary to term "hormones," which influence the circulatory organs and certain externally secreting glands—in the case of the suprarenals it is salivary glands, in the case of the pituitary it is the kidneys which are especially stimulated to secretion. The purely epithelial part of the pituitary, on the other hand, is closely connected with the growth and nutrition of certain of the connective tissues and especially of the bones, hyperplasia of the organ being accompanied by symptoms of gigantism and acromegaly. It seems, therefore, that from analogy we have some justification for inferring that the cortex of the suprarenals may yield a hormone which influences the growth and nutrition of certain tissues and organs. One might even be permitted to suggest that the integumentary tissues and the generative organs—with the relative development of which it is manifestly correlated—are directly under its influence. But I am getting away from the subject of my lectures and substituting for what is known regarding the functions of the suprarenals what is only conjectural. The digression is fascinating, but time will not allow me to pursue it. Perhaps within the next few years a successor of mine in this lectureship will be able to put before you as much positive knowledge regarding the cortex as we now possess regarding the medulla, the function of which seemed, no more than 15 years ago, as obscure as that of the cortex appears at present. And with the hope that this obscurity may speedily be removed, I cannot do better than terminate my discourse.

THE DRAINAGE OF DAWLISH (DEVON).—At a meeting of the Dawlish urban district council held on May 21st a scheme was adopted for modernising the whole of the drainage of the town. The cost of the undertaking is estimated at about £4000.

ON THE PREPARATION AND USE OF ANTIRABIC SERUM,

AND ON THE RABICIDAL PROPERTIES OF THE SERUM OF PATIENTS AFTER UNDERGOING ANTIRABIC TREATMENT; ALSO A NOTE ON THE BLOOD OF A PATIENT SUFFERING FROM HYDROPHOBIA.[1]

BY D. SEMPLE, M.D., M.CH. R.U.I., D.P.H. CANTAB.,
LIEUTENANT-COLONEL, R.A.M.C. (RETIRED); DIRECTOR OF THE CENTRAL RESEARCH INSTITUTE OF INDIA.

I.—ON THE PREPARATION AND USE OF ANTIRABIC SERUM.

THE idea of utilising the blood of an animal immunised with rabies virus to protect other animals against the disease was first put forward by Babes and Lepp in 1889. A few years later (1891) Babes and Carchez, experimenting with dogs, demonstrated that the blood of these animals when highly immunised was capable of protecting other dogs against the experimental inoculation of rabies, and in those not protected the incubation period was prolonged. They also proved that immune blood was capable of destroying rabies virus *in vitro*. It appears that Babes used the immune blood of man and dogs to treat some 12 cases severely bitten about the head by a rabid wolf. Of the 12 persons treated in this way there was one death. In severe cases he advocated mixed treatment—that is, the injection of immune serum in addition to Pasteur's treatment. Tizzoni and his fellow workers prepared an antirabic serum by immunising sheep with fixed virus attenuated by treatment with gastric juice. For this serum they claimed both prophylactic and curative properties and recommended its use in persons severely bitten about the head and face or in those coming late for treatment. Marie came to the conclusion that a prolonged period of vaccination in mammals was required in order to produce an active serum. Notwithstanding the experimental evidence produced by Babes, Tizzoni, and others in favour of antirabic serum, the subject has not attracted much attention and the use of the serum in antirabic institutes has, practically speaking, gained no headway, Pasteur's method of treatment being still universally employed.

TABLE I.—*Experiments to illustrate the Rabicidal Effect on Fixed Virus of the Serum of a Pony Highly Immunised against Rabies.*

No. of experiment.	Date of experiment.	Age of serum.	Proportion of serum and virus mixed.	Time and temperature serum and virus in contact.	Quantity inoculated.	Animal inoculated.	Method of inoculation.	Results.
1	1903. June 23rd.	24 hours.	Serum 1 vol. Virus 2 vols. 5% emulsion.	10 minutes at room temperature, about 20° C.	0 2 c.c.	Rabbit full grown.	Sub-dural.	Alive and well Sept. 1st.
2	Nov. 6th.	"	"	"	"	"	"	Alive and well three months after experiment.

6	"	"	Serum 1 vol. Virus 7 vols. 5% emulsion.	"	"	"	"	Developed rabies on the ninth day.
7*	"	"	Normal horse. Serum 1 vol. Virus 1 vol. 5% emulsion.	"	"	"	"	Developed rabies on the seventh day.
8*	"	"	"	24 hours at room temperature about 20° C.	"	"	"	"

* Control.

Remarks.—From the control Experiments 7 and 8 it will be seen that normal horse serum is devoid of rabicidal properties when mixed *in vitro* with an equal volume of fixed rabies.

Although the causal agent of rabies has not yet been discovered, the majority of the facts which we do know in connexion with the virus point to the probabilities of its being a germ and not a toxin; we are therefore more likely to be right in assuming that the serum of an immune animal is antimicrobic rather than antitoxic. Should this assumption turn out to be correct we are not likely to derive more than a limited benefit from any antirabic serum, no matter how highly the animal supplying it has been immunised. On the other hand, as pointed out by Babes and Tizzoni, its uses may lie in the direction of enabling us to grapple more successfully with the treatment of severely bitten and late cases when given as an adjunct to the ordinary method of treatment.

With this object in view, when director of the Pasteur Institute of India, I prepared a serum in 1902-03-04, and after satisfying myself that it possessed marked rabicidal properties when mixed with fixed virus I decided to use it as a preliminary to the usual method of treatment in severely bitten and late cases where there was good evidence to believe that the animals which inflicted the bites suffered from rabies. In these cases my object was to confer as high a degree of immunity as I possibly could, and within the shortest period of time. An active immunity such as is acquired by a patient who undergoes the ordinary method of antirabic treatment takes some time to become established, but a passive immunity such as is conferred by using the serum of an animal highly immunised can be acquired very quickly. In the former case the duration of immunity is long compared with the latter, a passive immunity being easily acquired and soon got rid of again. It is thus possible to give badly bitten and late cases the benefits of a passive immunity, pending the acquirement of a more durable active immunity resulting from the inoculation of rabies virus.

Young healthy ponies were the animals used in the preparation of the serum. Their immunity was accomplished by inoculating them first of all with attenuated fixed virus, commencing with the 14-day dried cord of a rabbit, and continuing the treatment daily by going down the series of attenuated cords until a 3 day cord was given. After this an 8 day cord was given, and the series again gone down by giving a larger dose every second day until a fresh cord was reached. The treatment was then put back to a 4-day cord and doses of increasing strength given every fourth day until a fresh cord was again reached. Immunisation was now continued by giving increasing doses of fresh fixed virus at intervals of from 10 to 15 days until the amount of virus represented by the fresh brains and medullæ of two rabbits of the series used to keep up rabies vaccine for the institute was given. This took about eight months to accomplish. Immunity was then kept up by repeating these large doses every four or five weeks. Blood was never drawn off sooner than 14 days after one of these large doses, more often 18 to 21 days after.

The serum when tested by mixing with fixed virus was found to have the property of rapidly destroying its virulence and rendering it harmless to rabbits when inoculated subdurally. When given hypodermically and in large doses to dogs and rabbits, before and after the subdural inoculation of fresh fixed virus, it had no appreciable effect in warding off the subsequent onset of rabies in these animals. This, however, is a very severe test and probably more than we can ever expect any antirabic serum to combat successfully, owing to the fact of the virus being directly implanted on to its specific germinating ground, the central nervous system; but it does not follow from this that it would fail in preventing or retarding the onset of rabies when infection took place by the bites of rabid animals.

---

[1] The experiments detailed in this paper were carried out by me at the Pasteur Institute of India, Kasauli, during the years 1903-04-05, when I was director of that institute.

The experiments detailed in Tables I. and II. make clear the above statements as to its rabicidal powers *in vitro* and its failure to prevent rabies when given hypodermically before and after the subdural inoculation of fresh fixed virus. In Table I. it will be seen that 1 volume of serum destroyed the virus in 3 volumes of a 5 per cent. emulsion of fresh fixed virus, but when the proportion of the virus was increased to 7 volumes the incubation period was only prolonged two days. In Table II. it will be seen that an equally potent serum failed to protect dogs when the virus was given subdurally and the serum hypodermically, although the doses of serum were large for animals weighing only about 12 pounds—*viz.*, 20 cubic centimetres for four days before and two days after the subdural inoculation of fresh fixed virus.

TABLE II.—*To Test whether Antirabic Serum has any Effect in Preventing the Onset of Rabies when the Serum is given Hypodermically and the Virus Subdurally.*

1903.

Experiment 1.

Dog, medium size (about 6 kilogrammes).
July 16th, 20 c.c. serum hypodermically.
,, 17th ,, ,, ,,
,, 19th ,, ,, ,,
,, 20th ,, ,, ,,
,, ,, Inoculated subdurally with fixed virus.
,, 21st. 20 c.c. serum hypodermically.
,, 23rd ,, ,, ,,
,, 30th. Commencing rabies *tenth day.*
August 3rd. Died from rabies.

Experiment 2.

Dog, medium size (about 6 kilogrammes).
Treated exactly as Experiment 1 and on the same dates.
August 2nd. Commencing rabies *twelfth day.*
,, 8th. Died from rabies.

Experiment 3 (control).

Dog, medium size (about 6 kilogrammes).
Not given any serum.
July 20th. Inoculated subdurally with fixed virus.
,, 29th. Commencing rabies *ninth day.*
August 1st. Died from rabies.

Experiments 1 and 2 go to prove that antirabic serum given hypodermically before and after the subdural inoculation of fixed virus in dogs has no appreciable effect in preventing the subsequent onset of rabies. Similar experiments were tried in a series of some eight or ten rabbits and in no instance had the serum any appreciable effect in warding off the onset of rabies when given hypodermically before and after the inoculation of virus subdurally.

In an experiment of this kind the pre-incubation period is done away with, and the virus immediately after being inoculated is on a soil eminently suited for its incubation and growth. I may here explain the meaning which we now attach to the terms *pre-incubation period* and *incubation period* when used in reference to rabies virus. By *pre-incubation period* is meant the time occupied by the virus in reaching the nerve centres from the seat of the infection—i.e., the period during which the virus grows along the nerves from the seat of the bites inflicted by a rabid animal until it reaches the nerve centres, when the true incubation period begins. By *incubation period* is meant the period which elapses between the time the virus comes in contact with the nerve centres and the onset of the first symptoms of the disease. An example may make this plainer. When the virus from a rabid dog (street virus) is inoculated subdurally in a rabbit a period of 14 days as a rule elapses before any symptoms set in. This is the incubation period for *street virus.* When Pasteur's fixed virus is inoculated subdurally in rabbits no symptoms appear until the seventh day. This is the incubation period for fixed virus.

The *pre-incubation period* is a very variable time and depends on several factors, such as individual susceptibility, quantity of virus inoculated, number and extent of the wounds, and whether in close proximity to the nerve centres; also whether few or many nerve fibres or large nerves are infected. These are factors which are bound to vary in every case of a bite by a rabid animal and on this account the pre-incubation period must also vary. We know that the incubation period as defined above is within narrow limits always a fixed time, but when added to a varying pre-incubation period we get a period of time elapsing between the infliction of a bite by a rabid animal and the onset of rabies or hydrophobia which can never be the same in any two cases. There are no symptoms to indicate either of these periods.

The pre-incubation and incubation periods taken together are often referred to as the incubation period for rabies virus, but from theoretical and practical points of view the distinction is of importance, owing to the fact that it is only during the pre-incubation period of the virus that prophylactic treatment can prove successful. Hence the necessity and importance of early treatment.

The seat of election of rabies virus is nerve tissue and the specific germinating ground the central nervous system. Once the virus has commenced to multiply in large nerve trunks as a result of wound infection it is doubtful whether ordinary treatment would be of any avail in preventing the onset of the disease. We know that when the virus is inoculated on the surface of the brain treatment of any kind is useless. On the other hand, we know that when infection takes place by the bite of a rabid animal early treatment by Pasteur's method is almost invariably successful. In a brain infection it is impossible to prevent the disease by early treatment.

An example intermediate between these two extremes would be a wound infection in which treatment had not been commenced until several weeks had elapsed. In a case of this kind we should have to assume that the virus had grown beyond the vicinity of the wound and had infected nerve trunks between the wounds and nerve centres. These are the cases which furnish the highest percentage of failures. Now the question arises, Would serum treatment followed by the ordinary treatment give a higher percentage of success in such cases? In the solution of this problem one of the first points to settle would be whether treatment with antirabic serum alone has any effect in warding off the disease in the case of animals bitten by other rabid animals. Many difficulties come in the way of answering this question satisfactorily, the main difficulties being the uncertainty of the disease supervening in a number of cases even without treatment of any kind and the possibility of a very prolonged pre-incubation period in others. In order to overcome these difficulties observations would have to be made in a large number of infected animals and for an extended period of time, some being treated with serum and the others not. In the absence of some definite basis of this kind one would not feel justified in treating human beings by the serum method only.

In the summer of 1904 I treated two infected animals by antirabic serum only. One, a dog severely bitten on the shoulders and ear by another dog subsequently proved rabid. Four days after being bitten 30 cubic centimetres of serum were injected into the tissues in the vicinity of the bites and the dog remained free from rabies for a year, when it was again bitten by a rabid dog and contracted rabies two months afterwards. No treatment was given after the second bites. The other animal treated was a horse, severely bitten on the hind leg by a rabid dog. 100 cubic centimetres of serum were injected hypodermically on the side of the neck ten days after the bites. Two months afterwards the horse developed rabies. 100 cubic centimetres of serum were probably a small dose for such a large animal.

During the years 1903-04, when director of the Pasteur Institute of India, I treated 202 patients with antirabic serum as a preliminary to the usual method of treatment. These were cases selected either because they were severely bitten or came late for treatment, and where there was good evidence to believe that the animals which inflicted the bites were rabid. In the majority of these cases 10 cubic centimetres of serum were given hypodermically when they presented themselves for treatment, and next day the usual treatment was proceeded with. In some of the cases the serum treatment was repeated on the second day, and the usual treatment proceeded with on the third day.

Of the 202 cases treated in this way three were failures;

* Repeated with serum kept in ice chest since April 18th.

Remarks.—Of these 22 experiments 11 developed rabies. The shortest period of incubation was nine days and the longest 43 days. Average 13·5 days, as compared with seven days, the normal period of incubation for fixed virus. Of the remaining 12 experiments five remained healthy and seven died at periods varying from eight to 48 days after the experiments. Three of these seven fatal cases showed symptoms of wasting before death and four died suddenly, being apparently well the day before.

one contracted hydrophobia during treatment and one within 14 days after the completion of treatment. The average time which elapsed between the infliction of the bites and commencement of treatment in these 202 cases was 10·3 days. In a number of the worst cases of all serum was injected into and around the wounds and none of these proved failures. Owing to the fact that serum treatment was followed by the ordinary treatment one cannot say for certain whether any real benefit was derived from the use of the serum, but taking into consideration the severity of these cases the probabilities are that the preliminary treatment with serum was instrumental in saving some of them from hydrophobia.

In the absence of any more definite proof as evidenced by a more extended trial one cannot say anything more in favour of the serum except that it may turn out to be a valuable first dressing to apply to the wounds produced by rabid animals soon after their infliction, in addition to being inoculated into the tissues in their vicinity.

To sum up, its uses are likely to be in the following directions: 1. As an adjunct to the usual treatment in severely bitten and late cases. 2. Direct and early application to the wounds produced by rabid animals. 3. Injection into the tissues in the vicinity of the bites.

II.—THE RABICIDAL PROPERTIES OF THE SERUM OF PATIENTS AFTER UNDERGOING ANTIRABIC TREATMENT.

Knowing that the serum of an animal highly immunised against rabies possesses in a marked degree the property of

17	" 23rd.	17 "	"	"	"	" 31st.	8 "	Incubation period prolonged one day.
18	" 24th.	18 "	"	"	"	June 1st.	"	" " "
19	" 25th.	19 "	"	"	"	—	—	Alive and well June 30th, 36 days after the experiment. *Experiment off.*
20	" 26th.	20 "	"	"	"	June 3rd.	8 days	Incubation period prolonged one day.

Remarks.—Of these 21 experiments 16 developed rabies. The shortest incubation period was eight days and the longest 12 days. Average 8·8 days, as compared with 7 days, the normal period of incubation for fixed virus. Of the remaining five experiments two remained healthy and three died at periods varying from 27 to 49 days after the experiments, showing symptoms of wasting before death.

destroying rabies virus *in vitro*, it is only reasonable to expect that the serum of a patient after undergoing antirabic treatment should also possess similar properties, but not necessarily in such a marked degree as in the case of an animal specially and more highly immunised. If this be true, there should be no difficulty in testing the rabicidal action of the serum of a treated person on living rabies virus, because on the completion of a successful course of antirabic treatment an active immunity against rabies has been acquired, an immunity which is in all probability germicidal rather than antitoxic, as evidenced by the action of the serum of an immunised animal on fresh fixed virus. The subject is important from a practical point of view, because it opens up the possibility of testing the efficacy of antirabic treatment in any particular case. In the event of the serum of a patient on completion of treatment giving evidence of a well-marked rabicidal action one would feel justified in inferring that his immunity was of a high order. A patient whose serum when mixed with fresh fixed virus and inoculated subdurally in rabbits failed to cause any delay in the incubation period of rabies might well be looked upon as a person having a low degree of immunity or possibly none at all. In a case of this kind further treatment would be indicated.

When testing the serum of a patient immediately on completion of treatment it is doubtful whether we should have to take into consideration the possibility of a negative phase. When we examine the conditions under which patients are treated it is difficult to believe that a negative phase ever does occur in this particular method of immunisation. Patients undergoing antirabic treatment are given one or two doses of rabies virus daily for a fortnight or three weeks, and sometimes longer. Under these conditions a negative phase occurring early in the treatment would become cumulative, a condition which would be incompatible with the main object of treatment—viz., to confer a high degree of immunity in the shortest possible period of time. The explanation is probably due to the fact of the daily doses being just sufficient to bring about a reaction capable of stimulating the production of antibodies, and that the immunity thus induced increases daily from the time treatment is commenced. On this assumption we would get an accumulation of antibodies and not a cumulative negative phase. The reverse of this would mean failure, a result which in practice we know to be quite the exception.

TABLE VI.—*Experiments to Test the Effects on Fixed Rabies Virus of the Serum of a Patient after Undergoing Antirabic Treatment for 24 Days but not by the Intensive Method. Serum and Virus (1 per cent. Emulsion) Mixed in Equal Volumes and Inoculated Subdurally in Healthy Full-grown Rabbits.*

19	,, 3rd.	21 ,,	,,	,,	,,	—	—	Alive and well June 30th, 27 days after the experiment. *Experiment off.*
20	,, 4th.	22 ,,	,,	,,	,,	June 17th.	13 days.	Incubation period prolonged six days.

Remarks.—Of these 20 experiments 10 developed rabies. The shortest incubation period was nine days and the longest 34 days. Average 15 days, as compared with 7 days, the normal incubation period for fixed virus. Of the remaining 10 experiments, seven remained healthy and three died suddenly at periods varying from 13 to 51 days after the experiment, being apparently well the day before.

Procedure Adopted.

A uniform line of procedure was adhered to throughout, and only fixed virus was used as a test for the serum. Strict aseptic precautions were observed. The blood was taken from the finger, filled into glass capsules, allowed to clot, and placed in a dark cupboard at room temperature (about 22° C.) for 24 hours. The virus was obtained daily from the fresh medulla of one of the rabbits of the series the cord of which was used for the preparation of vaccine at the institute. For each experiment the virus was taken from the medulla of a different rabbit, and only from an animal which had died from rabies that day. A small portion of the medulla was removed, carefully weighed, then finely emulsified in a conical glass with a measured quantity of sterile normal salt solution, so as to make a 1 per cent. or 5 per cent. emulsion, as the case might be. When the emulsion had stood for from 10 to 15 minutes so as to allow any heavy particles to fall to the bottom a measured amount was pipetted off from the upper part and well mixed with an equal volume of clear serum. The mixture of the virus and the serum was then placed in an incubator at a temperature of 37° C. for one hour and when taken out was again well mixed before being filled into the inoculating syringe. Healthy full-grown rabbits were used in all cases and the inoculations were carried out subdurally after trephining in the usual way. Daily observations were made on each experiment.

TABLE VII.—*Experiments to Test the Effects on Fixed Rabies Virus of the Serum of a Patient after Undergoing the Ordinary Course of Antirabic Treatment lasting 20 Days. Serum and Virus (1 per cent. Emulsion) Mixed in Equal Volumes and Inoculated Subdurally in Healthy Full-grown Rabbits.*

Remarks.—Of these 19 experiments nine developed rabies. The shortest incubation period was eight days and the longest 12 days. Average 10 days, as compared with 7 days, the normal incubation period for fixed virus. Of the remaining 10 experiments seven remained healthy and three died suddenly at periods varying from 15 to 25 days after the experiment.

On analysing the results of these experiments it will be noticed that the animals inoculated may be divided into two classes: (1) those that developed rabies and (2) those that did not develop rabies. In the former class the animals showed unmistakable symptoms of rabies and died from that disease. In the latter class some died and others remained healthy. In those that died in Class 2 none showed any symptoms of paralysis but some gradually wasted before death and others died suddenly without any wasting. It is just possible that many of the deaths in Class 2 were due to the neurotoxic action of the serum on the brain.

When we analyse the conditions under which the patients who supplied the serum were immunised—viz., with the spinal cords of rabbits—an immune serum produced under these conditions must necessarily contain antibodies capable of giving rise to cytolytic action on the nerve-centres of rabbits. That the symptoms of wasting took some time to develop in some fatal cases, and failed to do so in others, was probably due to the small quantity of serum present in the mixture inoculated on to the surface of the brain. As evidence in support of the hypothesis of a cytolytic action of the serum on the brain, I may mention that in several cases (not given in these experiments) in which the antirabic serum from a highly immunised pony was given hypodermically in large doses to rabbits, with the object of protecting them against the experimental infection of wounds with rabies virus, several of the animals died suddenly some weeks afterwards; some showed symptoms of wasting before death, and others did not. The neurotoxic action of the serum was in all probability the cause of death in these cases.

It is difficult to explain why the serum of a patient after antirabic treatment may one day give evidence of only prolonging the incubation period for a few days, and on the next day of complete rabicidal action. A possible explanation might be that the amount of virus in a 1 per cent. emulsion from the medulla of different rabbits varies widely. On the other hand, an equally plausible explanation might be that the rabicidal substances in the serum of a treated patient vary from day to day. It would be impossible to say whether either or both of these hypotheses explain the variation in the results obtained.

III.—EXPERIMENTS WITH THE BLOOD OF A PATIENT SUFFERING FROM HYDROPHOBIA.

In April, 1905, a patient arrived at the Institute in the early stages of hydrophobia. I took a few capsules of blood from his finger, some of which I citrated to the extent of 0·5 per cent. citrate of sodium and others were allowed to clot in the ordinary way. Immediately after the citrated blood was collected three healthy full-grown rabbits were inoculated subdurally with ½ cubic centimetre each. None of these animals developed rabies. (See Table VIII.) These results lend confirmation to Pasteur's statement that the virus is not found in the blood. The serum from the non-citrated blood was mixed with an equal volume of a 1 per cent. fixed virus emulsion, then placed in the incubator for one hour at 37° C., and two rabbits inoculated subdurally with 0·15 cubic centimetre each. Both these animals developed rabies, one on the tenth day and the other on the eleventh day after the experiment—a prolongation of the incubation period for fixed virus of three and four days respectively. (See Table IX.). In these two experiments the serum was kept in an ice chest for 48 hours before being used, so there is a possibility that it may have lost to some extent in complement. The fact of there being a prolongation of the incubation period to the extent of three and four days would indicate that during the onset of hydrophobia an attempt is made to combat the virus by the elaboration of antibodies. The patient from whom the serum was obtained was in the early stages of the disease, and the only symptoms he had at the time were difficulty in swallowing and a little mental excitement. On the second day his symptoms were more marked and he died on the third day.

TABLE VIII.—*Experiments with the Blood of a Patient Suffering from Hydrophobia, when Inoculated Subdurally in Rabbits.*

No. of experiment.	Date of experiment.	Animal inoculated.	Substance inoculated.	Quantity inoculated.	Method of inoculation	Results.
	1905.					
1	April 26th.	Rabbit full grown.	Blood of a patient suffering from hydrophobia.	0 5 c.c. (citrated 0·5 %).	Subdurally.	Alive and well June 24th, two months after the experiment.
2	"	"	"	"	"	"
3	"	"	"	"	"	Died May 15th, but showed no symptoms of rabies before death. A portion of the medulla used to inoculate another rabbit failed to give it rabies.

Remarks.—The blood of a patient suffering from hydrophobia failed to give rabies to rabbits in the above three instances when inoculated subdurally.

TABLE IX.—*Experiments with the Serum of a Patient suffering from Hydrophobia, when Serum mixed with Fixed Virus and Inoculated Subdurally in Rabbits.*

No. of experiment.	Date of experiment.	Age of serum.	Proportion of serum and virus mixed.	Time and temperature serum and virus in contact before inoculation.	Quantity inoculated.	Date of commencing paralysis.	Incubation period.	Results.
	1905.							
1	April 29th.	48 hours (in ice chest).	Serum 1 vol. Fixed virus 1 vol. 1 % emulsion.	1 hour; 37° C.	0·15 c.c.	May 8th.	10 days.	Incubation period prolonged three days.
2	"	"	"	2 hours; 37° C.	"	" 9th.	11 days.	Incubation period prolonged four days.

Remarks.—In these two experiments the incubation periods were 10 and 11 days respectively, as compared with 7 days, the incubation period for fixed virus either used by itself or mixed with normal human serum.

TABLE X.—*Control Experiments with Normal Human Serum and Fixed Rabies Virus.*

No. of experiment.	Date of experiment.	Source of serum used.	Proportion of serum and virus mixed.	Time and temperature serum and virus in contact before inoculation.	Quantity inoculated.	Date of commencing paralysis.	Incubation period.	Results.
	1905.							
1	March 22nd.	Normal man.	Serum 1 vol. 24 hours old virus 1 vol. 1% emulsion.	1 hour; 37° C.	0·15 c.c.	March 29th.	7 days	Normal period of incubation for fixed virus when inoculated subdurally in rabbits.
2	May 23rd.	"	"	"	"	May 30th.	"	"
3	" 24th.	"	"	"	"	" 31st.	"	"

5	" 26th.	"	"	"	"	" 2nd.	"	"
6	" 27th.	"	"	"	"	" 3rd.	"	"
7	" 28th.	"	"	"	"	" 4th.	"	"
8	June 23rd.	"		"	"	" 30th.	"	"

Remarks.—In all these controls the serum was derived from a different person for each experiment, and the fixed virus from a different rabbit. Full-grown rabbits were used, and the experiments were similar in every detail to those for which they are controls, except that normal human serum instead of serum from a treated person was used. Several more controls done at different times might be added on, but these would serve no more useful purpose than the above, for the results were invariably the same, viz., *rabies seventh day.*

REMARKS ON THE TABULATED RESULTS.

Tables I. and II. require no further comment.

Table III.—Ordinary treatment, but extended over a period of 22 days. 11 out of 22 experiments developed rabies; average period of incubation nine days.

Table IV.—Light treatment for 18 days. The patient was of alcoholic habits and it was doubtful whether he had been infected, hence the light treatment over an extended period. 8 out of 10 experiments developed rabies; average period of incubation 9·7 days. The result of this series of experiments would seem to indicate that light treatment does not confer a high degree of immunity.

Table V.—An example of very light treatment lasting only ten days. 16 out of 21 experiments developed rabies; average period of incubation 8·8 days. Here again it would seem that light treatment does not confer a high degree of immunity.

Table VI.—An example of ordinary treatment prolonged for

a period of 24 days, but not by the intensive method. 10 out of 20 experiments developed rabies; average period of incubation *15 days*. The results of this series of experiments indicate that prolonged treatment confers a higher degree of immunity than treatment extended over a shorter period of time.

Table VII.—Ordinary treatment lasting 20 days. 9 out of 19 experiments developed rabies. Average period of incubation *10 days.*

Tables VIII., IX., and X. require no comment.

Further information will be found in the footnotes to the above tables.

SUMMARY OF CONCLUSIONS.

1. By immunising horses with fixed rabies virus it is possible to prepare a serum having well-marked rabicidal *properties.* Normal horse serum is devoid of these properties.

2. The rabicidal properties of this serum can be tested by mixing it with fixed virus and subsequently using the mixture to inoculate susceptible animals, such as rabbits, subdurally.

3. The *indications for the use of* such a serum would seem to be as an adjunct to the ordinary method of treatment in *severely bitten and late cases.* In severely bitten cases coming early for treatment it might also be injected into the *wounds* and *the tissues* in their vicinity.

4. The serum of patients after undergoing a course of *antirabic treatment also gives evidence of containing* rabicidal substances and the presence of these substances *can be demonstrated in a manner similar* to that mentioned in Conclusion 2. Normal human serum is devoid of these *properties.*

5. The rabicidal substances in the serum of a patient after *antirabic treatment are a possible index of the amount of* immunity conferred and the efficacy of treatment.

6. Prolonged treatment confers a higher degree of immunity, as judged by the rabicidal effects of the serum on fixed virus, than treatment *extended over a shorter* period of time.

7. The *blood of a patient suffering from hydrophobia fails* to infect rabbits when inoculated subdurally.

8. The serum of a patient in the early stages of hydrophobia is capable of prolonging the incubation period for fixed virus when mixed *in vitro* and inoculated subdurally in rabbits.

Kasauli, Punjab, India.

SOME RECENT CASES OF CÆSAREAN SECTION.

BY J. B. HELLIER, M.D. LOND.,
OBSTETRIC PHYSICIAN TO THE GENERAL INFIRMARY, LEEDS.

CASES 1 AND 2. *Cæsarean section performed twice on the same patient.*—A woman, aged 24 *years,* had a *generally* contracted pelvis, of which the true conjugate was about three and a half inches. Two *previous* children, delivered with forceps, had both succumbed during delivery, and a third child, born *after the induction* of premature labour, lived only a few minutes. The patient was very anxious to have a *living* child and in view of the safety of the modern operation such cases are very suitable for treatment by hysterotomy. From data given by the patient it was calculated that on March 28th, 1905, she would be within a few days of term. Operation was performed on this day and presented no difficulty, and, except for some *temporary bronchitis,* recovery was complete and satisfactory. Unfortunately, the child was not mature, for it weighed *only* four pounds and measured 17 inches. It was incubated but lived only four days. This shows that if the data given by the mother are *wrong* there is danger of delivering the child prematurely if we do not wait for labour *to begin.* The same woman was admitted in May, 1906, in the last month of her next pregnancy. Her last period had been from August 3rd to 9th, 1905, so that labour was expected about May 16th or later. It began *spontaneously on May 8th,* at 7 P.M., and Cæsarean section was performed at 5 30 the following morning. There was hardly any trace of the previous uterine incision, but some omental adhesions required separation. The placenta was anterior and required to be separated first. The child was a living female and throve well. She weighed six and a *half pounds.* In order to carry out the wish of the father and mother partial salpingectomy was performed in order to prevent future conception. Recovery was not very smooth, being complicated by some suppuration in the lower end of the wound, probably due to a uterine stitch abscess, which, however, was successfully treated by inserting a small rubber drainage-tube. She was discharged cured on June 16th.

CASES 3 AND 4. *Another patient on whom Cæsarean section was twice performed.*—A woman, aged 27 years, was rickety and did not walk till five *years of age.* She had a flat, rickety pelvis with oblique conjugate of about three and three-quarter inches. In *each of four previous labours* she had failed to bear a living child. They had been foot presentations and there had *in each instance been much* difficulty in delivering the after-coming head. Labour was expected *on April 17th and the operation* was *performed* on the 18th, before labour had commenced. There was no difficulty or complication and the mother suckled her child. It weighed only five pounds and I decided that in *any future pregnancy I would wait till labour began.* She was re-admitted on Oct. 11th, 1907, saying that she expected *to be confined in the latter half of October. Labour* pains did not begin till Nov. 8th. The abdomen was carefully *opened along the scar of the old incision. There* was a band of peritoneal adhesion between the uterus and the abdominal wall, *but hardly any scar in the uterus.* The placenta lay anterior and was removed first. The mother made an uncomplicated *recovery and having a good* supply of milk suckled the child, which has thriven very well. It weighed nearly eight pounds at birth.

CASE 5. *Dwarf pelvis.*—This case was that of a rickety dwarf 44 inches *in height. There* was a marked lordosis in the lumbar region and the tibiæ and femora were much curved. There was a *small flat pelvis, the* promontory filling the pelvis and coming within one and three quarter inches of the pubes. The liquor amnii discharged on April 10th, 1906, and *operation* was performed at once. There were *no difficulties or complications.* The patient was sterilised. The child weighed six and a half pounds and throve well. At the operation I noticed some free ascitic fluid in the pelvis, as in some other cases. Good *recovery* ensued.

CASE 6. *Flat pelvis.*—The patient was a married woman, aged 34 years. She was sent in by Dr. C. H. Moorhouse because her two previous labours had resulted in *stillborn* children who died in delivery. The true conjugate was about three and one-eighth inches. *Operation* was performed on Jan. 9th, 1907; recovery ensued without complications. The patient was not sterilised. The child was a fairly well developed male but *unfortunately* died in three and a half hours from atelectasis pulmonum, as verified by post-mortem examination. Labour had commenced before operation.

CASES 7 AND 8. *Two operations on the same patient.*—Case 7 is of interest because the operation was done *for a somewhat contracted pelvis and also as a method of* dealing with ante-partum hæmorrhage. The mother was a Jewess. She had had one living child seven years before, although the true conjugate was about three inches. Before admission she had lost a great deal of blood but the fœtal heart was audible, beating *126 in the minute.* She was very anxious to have a living child and labour had begun. Judging that the safest treatment for mother and child was to deliver by hysterotomy I operated at once (Feb. 3rd, *1907).* The *placenta was attached* to the posterior uterine wall above the "danger-zone," but the lower part *was already separated,* and *to this* dark blood clot was adherent. The child was a well-developed male, weighing $6\frac{1}{2}$ pounds. It throve well and the mother recovered without complication. *On May 3rd,* 1908, Cæsarean section was again performed on this patient and a living male was delivered *without complication.* Labour had begun. *In* this case (Case 8) salpingectomy was performed. Good recovery.

CASE 9. *Osteomalacia.*—This patient was born in Leeds and had lived a few miles *lower down the river.* She had had no serious illness up to marriage at the age of *27 years* in 1892. Her first two pregnancies terminated in normal delivery of living children at term, then came an *abortion at the third month,* and then a full-term easy labour. Her fifth pregnancy ended in *abortion at three months and* her sixth in the delivery of a *stillborn* child said *to have been* dead a week. After this confinement—*i.e., about seven years* ago—she first noticed symptoms of osteomalacia—namely, lameness with pain on walking and in the bottom of the back on stooping. The seventh pregnancy ended in a still-birth. At the end of the eighth pregnancy she was brought in labour to the Leeds Infirmary (March 18th, 1906). She said that she had lost much in stature and she walked very lamely, stooping forwards, and she complained of pain when lifted in bed. The head was presenting. The pubic arch was narrowed, so that in trying to take the oblique conjugate the finger would not pass up to the bottom of the symphysis. There was rostration of the os pubis. As there were grounds for thinking that the vagina was not aseptic Cæsarean section was not performed, but the child was delivered by version, the after-coming head requiring perforation. I thought the pubic arch opened a little during extraction, as sometimes is the case in soft-boned pelves of this sort. The patient made a good recovery. She was admitted again on June 18th, 1907, in the last month of her ninth pregnancy. She was very sallow and very lame and had lost weight. Cæsarean section was performed on June 22nd at about the time when labour was supposed to be due. It presented no difficulties and both ovaries were removed with a view of curing the osteomalacia. She recovered without complication. The child was a puny male weighing barely four pounds. He was incubated and every effort made to rear him. He could swallow and did not at first suffer from vomiting or diarrhœa. At the age of three weeks Dr. W. H. M. Telling kindly took him under his care at the Hospital for Women and Children. As diluted milk did not then agree with him he was fed on peptonised milk and was kept in the incubator. The temperature was always subnormal, and if an attempt were made to take him out of the incubator the condition would become worse. He never weighed above four pounds and died suddenly in the eleventh week of life. In December, 1907, the mother reports that she keeps very well "in herself" and that she has less pain in her legs, is not so lame, and can get about much better.

As I have published a clinical lecture on the history and technique of Cæsarean section with nine previous cases performed in this hospital,[1] I will here only note a few points which these nine additional cases suggest. So far as the mother is concerned it is entirely satisfactory to operate before labour begins, but the interests of the child are best secured by waiting until the full term of pregnancy, for the longer it can be incubated in its mother's womb the better it is qualified to live and thrive in the world outside. Calculations as to the duration of pregnancy are notoriously uncertain, and, indeed, the period of utero-gestation is not a fixed quantity. In all ranks of society we hear of unborn children who are considered to be *overdue*. The fact is that the fruit falls when it is ripe and it is a mistake to gather it prematurely; and there seems to be some danger of doing so, judging by my experience, if labour be anticipated. The operation is very easy and safe in experienced hands, granting only that the patient has not been the subject of ill-advised attempts to deliver in other ways and that she is in an unimpaired condition, and that the parturient canal is aseptic. I do not think that any personal precautions of the operator can give absolute certainty that the vagina and cervix are quite free from pathogenic organisms. A case is on record where a child delivered by Cæsarean section was found to have the conjunctiva infected by purulent ophthalmia, so that presumably infection was present above the os internum. There is a possibility of a uterine stitch abscess sometimes arising through infection from the endometrial surface of the uterine incision. If there should be any reason to suspect this after operation the treatment would be to take out the lowest abdominal stitch and insert a rubber drainage-tube. During operation it is well not to make the incision too low, but avoiding the lower uterine segment to extend upwards rather than downwards.

In regard to sterilising, my practice has hitherto been to be largely guided by the expressed wishes of the two parents. I think that Cæsarean section ought to be more frequently performed for contracted pelves when experience has proved that the mother cannot bear living children even though the pelvic diameters place the case on the border line of possible delivery as laid down in text-books. Osteomalacia is rare in the West Riding as in other parts of England, but I have seen two cases in the last seven years. The case here recorded seems to have benefited decidedly from oöphorectomy, as osteomalacia usually does.

Leeds.

THE PROTRACTED USE OF DIGITALIS.

BY R. E. ACHERT, M.D.,

CONSULTING PHYSICIAN TO THE MUNICIPAL MINERAL WATER HOSPITAL AT BAD NAUHEIM (GERMANY).

THE use of digitalis as a drug has been compared with that of the whip applied to an overworked horse. The *protracted use* of the drug may well be looked upon as crutches which enable sufferers from cardiac diseases to hobble along for a very long time to come. It was chance that led to the appreciation of this method. A highly intelligent engineer suffering from hypertrophy of the heart had for five years continuously taken small doses of digitalis—his state of health being under careful observation during that period—without any phenomena of poisoning manifesting themselves. Kussmaul utilised this case at the time in order to discuss the question of digitalis poisoning consequent upon so-called accumulation. This method of applying the drug by way of protracted medication and in small, almost homœopathic, doses, so to speak, dates back, however, much farther than is generally assumed. For from the *Charité-Annalen* one learns that Fräntzel (whose writings are an almost inexhaustible source of information for later authors) already employed the *dosis refracta* of digitalis.

It is certain that digitalis administered in the way which was formerly customary when employed for a long period of time, even in small doses, had a so-called cumulative effect in many instances, whilst in others such medication proved quite ineffective. Such refractory cases, however, will always be met with. Eichhorst has shown that it is necessary for the cardiac muscle to be sufficiently capable of performing its function if digitalis is to take effect. Should this not be the case the effect does not ensue, and provided the digitalis preparation used is a good and reliable one its failure to produce an effect on the heart suggests a thoroughly unfavourable prognosis, for in such cases no other remedy is likely to prove of service.

Again, in other cases the cumulative effect takes place because the excretion of the active substances does not keep pace with the absorption, and strict supervision, therefore, becomes imperative. It was strange that such a cumulative effect is not constant. Some authors have noticed it and thereupon prohibited its protracted administration; others have not observed it or have done so but seldom, and continued its use. Naunyn may be right in advocating the view that in general there are no urgent reasons for fearing the cumulative effect of the drug. Until very recently, however, we had no explanation of the cumulative effect; experimental evidence was absolutely lacking.

From the recent researches of Focke and others we know how varied is the amount of efficacious substances contained in digitalis leaves and how fluctuating the proportion of active principles. Hence we can well imagine why a cumulative effect ensues in one case and remains absent in another.

This subject had been made clearer and more understandable from the recent writings of Cloëtta,[1] who showed by experiments on animals that the effect produced by crystallised digitoxin differed from that due to the amorphous digitoxin.

Fränkel[2] was the first to make experiments on animals He employed digitoxin in the crystallised form and found that injections of very small doses into cats *were followed* by cumulative effects. Now, when it was observed that digalen (digitoxinum solubile Cloetta) did not produce a cumulative effect in the respective patients the fact was very remarkable, considering that the majority of the authors looked upon the cumulative effect as being characteristic of a serviceable preparation. It was all the more puzzling since in the experiments on animals no difference was observed in the effect produced on the cardiac muscle by digalen and crystallised digitoxin respectively (Freund,[3] Sasaki[4]). Experiments according to Fränkel's method had hitherto, it is true, not yet been made. The fact was borne out by the increasing number of results obtained in practice showing that the administration of digalen to sufferers from cardiac diseases was not followed by cumulative effects.[5] I have not observed any such effect in the numerous cases under my care.

[2] Archiv für Experimentelle Pathologie und Pharmacologie, vol. li.

[3] Zeitschrift für Experimentelle Pathologie und Therapie, 1905, vol.

[4] Berliner Klinische Wochenschrift, 1905, No. 26.

[5] The cumulative effect was not observed by Dennig (Jahrbuch

Now Cloetta's experiments on animals have clearly demonstrated that there exists a difference between these preparations, inasmuch as after protracted digalen treatment no cumulative effect was observed in cats, whereas crystallised digitoxin caused in the same animals vomiting, salivation, and anorexia, besides arrhythmia. Cloetta has shown that it is not the molecular weight of the substance (280 as against 552 of crystallised digitoxin) which decides the toxic effect produced, but *the fact that the preparation has been crystallised.*

Several French preparations containing crystallised digitoxin, after trials made for the sake of verification, were found to have a cumulative effect. By way of analogy Cloetta refers to the behaviour of an amorphous form of physostigmine, which also differs in its action from that of the crystallised form (Harnack). Hence the cumulative effect observed by many authors to follow the use of digitalis explains itself by the fact that in the digitalis leaves employed the amorphous digitoxin contained in the fresh preparations must have been transformed into a state analogous to the crystallised digitoxin, a fact which has likewise been proved by Cloetta.

Cloetta's experimental researches are the first which have reliably demonstrated the fact that there is a digitalis preparation—namely, digalen—which does not possess any dangerous or disagreeable cumulative action.

The question now arises, In which of the cardiac diseases is it advisable to resort to protracted medication? Even the acute disorders frequently required a longer period of medication than that which was customary, and one often had recourse to the expedient of giving strophanthus or camphor in between, resuming the digitalis medication after an interval of several days. Even more than the temporarily disturbed valvular defects *do the chronic affections of the cardiac muscle need protracted treatment.* Seeing that these affections predominate in medical practice the prolonged use of digitalis assumes a still greater importance. In patients suffering from fatty heart digitalis, as a rule, does not agree. In the case of fatty degeneration even digitalis cannot save what has been lost already. In neurotic diseases of the heart good results are but seldom seen except when the cardiac muscle is involved. Accordingly the following indications are left as being the most important—viz., myocarditis in all stages and of any pathogenesis, myasthenia cordis chronica with or without dilatation and hypertrophy, and weakness of the heart in the case of hypertrophy of the left side of the heart after nephritis of long standing.

Let me now describe briefly how the treatment is carried out. Kussmaul and Naunyn recommended protracted medication in all cases in which the usual mode of treatment did not produce long-lasting results and in which the phenomena of cardiac insufficiency reappeared within a very short time. They prescribed the digitalis leaves in substance in the form of powders or pills, 0·05 to 0·1 gramme per day; if required the dose was given twice a day. When the effect diminished the dose was afterwards increased. These authors laid stress on the fact that after long-continued use a lasting result might be ultimately obtained and then digitalis might be dispensed with.

This mode of treatment may, it is true, in conjunction with strict supervision, be free from danger and be serviceable, but in view of the unreliability of the drug one must always be prepared to face a cumulative effect. Seeing, however, that in digalen we have at our disposal a preparation—in fact, the only one of the numerous digitalis preparations produced during the last few years—which is exempt from a cumulative effect, it is better than any other officinal preparation suited for protracted medication, as here all the dangers inherent in the other preparations are absent.

As regards the pharmacology of this preparation I would refer readers to Cloetta's respective essays.[6] I would add a few remarks about the dosage in the case of protracted medication. Seeing that 0·15 gramme of folia digitalis corresponds to 1 cubic centimetre of digalen = 20 drops (16·9 minims), from 7 to 14 drops (= say 6 to 12 minims) would have to be administered once or twice per diem in the case of protracted medication; and, indeed, this small dose suffices to maintain the compensation in suitable cases.

Since the introduction of digalen I have given it in all suitable cases and always with satisfactory results. No disagreeable gastro-intestinal disturbances at any time manifested themselves. Of all the allied preparations I deem digalen most suitable for protracted medication. The usefulness of this drug in cardiac disease has recently been highly spoken of by Dr. Ernest von Leyden, my friend and respected teacher.

SUPRARENAL HÆMORRHAGE IN AN INFANT: ITS RELATION TO HÆMOPHILIA.[1]

BY B. G. MORISON, M.D., C.M. EDIN.

THE following case of hæmorrhage into the suprarenal body presents certain features which may, I hope, justify its publication. These are—the occurrence of the lesion very shortly after birth, its characteristic type, and particularly the observation of a hæmophilic tendency prior to any of the more obvious signs of adrenal injury.

A male infant, a first child, was born about the middle of the ninth month of pregnancy after normal labour. The umbilical cord, a thick one, was tied three times in succession on account of bleeding which appeared at the seat of ligature. The ligature was made thick and its material varied in order to obviate damage to the vascular walls, but apparently in vain. On the third occasion a little blood was seen to burst through the cord (uninjured here) above the ligature. Finally, the cord was bound round with double cyanide gauze, kept dry, and regularly dusted with boric powder. It is my practice to allow a child to cry before tying the cord. I mention this because Kiwisch and others have attributed hæmorrhage in newly born infants to undue haste in applying the ligature. Nothing further was noted in this case until the ninth day, when the child seemed weak and would not take the breast. There was some jaundice but the stools were healthy and the cord was dry. There was no umbilical redness. On the tenth day the infant was stronger; snuffling was noticed and small doses of grey powder were prescribed in view of any possible specific taint, though the history did not justify this suspicion. The stools were green. On the eleventh day the cord was nearly off but was still attached. Seen again on the seventeenth day the child was feeding fairly well; the cord had just become detached. On the two following days the parents noticed some rather bright-red patches on the chin. The child became somnolent and refused nourishment, but had neither sickness nor diarrhœa. On the day following I was sent for. The child had suddenly become much emaciated and generally worse during the night. There were bright-red patches on the chin, round the mouth, toward the back of the scalp, and at the tips of the fingers and toes. The scrotum was rather full, red, and slightly eroded. The navel, still being dusted with boric powder, was surrounded by a red, rather prominent ring within which was an unhealed surface. At the circumference of this there was slight separation of cuticle. The heart beat was fairly strong and for the first time a rise of temperature was noted (100·8° F.). The child was "slightly convulsed" all day, as I learned afterwards. At 9 P.M. the temperature was 102°, the erythematous spots were disappearing, but the scrotum was more full and livid. The stools were yellow for the first time in ten days. Death occurred at 11 P.M. on this the twentieth day after birth.

Post-mortem examination showed a red lividity about the chin and mouth, the scrotum full and livid. The thoracic and abdominal viscera generally were apparently normal but for the presence of passive congestion; the spleen was of a deep slate-blue colour, not softened, and on section showing nothing noteworthy; the pancreas was normal. The right suprarenal body was also normal though passively congested; the left was very dark slate-blue. Opened *in situ* it at once collapsed and shed its fluid contents into the abdomen. On examination it appeared to be converted into a blood sac, was very soft, and partly torn in removal. There were no signs of inflammation spreading up from the umbilicus and the umbilical cord inside the abdomen was small, pale, and

[1] From notes communicated to the Æsculapian Society.

evidently not diseased. The brain was not examined. The microscopic report by the Clinical Research Association a considerable time after hardening in formalin and methylated spirit is as follows: "The right suprarenal shows no abnormal appearances. The left suprarenal is much broken up but there are the remains of hæmorrhage in its medullary substance, both in the form of extravasated corpuscles and as granules of pigment. The condition is probably the result of strain and not of disease."

The family history in this case is not a good one. Both grandmothers had died from carcinoma and the maternal grandfather from phthisis. I can find no evidence of specific taint nor have I any reason to suspect this. Clinically the case is typical of hæmorrhage into the adrenal medulla and its character was verified by the necropsy. It appears to me that its chief interest and significance depend upon those *earlier evidences of failure of* the vaso-tonic function of the medulla which have been described; the signs of a hæmophilic weakness, the general atony, the slight preliminary purpura, and increasing lassitude which culminated in the final purpuric explosion, nervous and general collapse. It appears as if there had been present at birth, or possibly before it, in the medulla some premonitory congestion or slight hæmorrhage followed by a sudden final apoplexy, a condition of things which finds its counterpart at the opposite extreme of life in the cerebrum. How far hæmophilia is dependent on adrenal inadequacy remains to be proved, but the present case is suggestive in this connexion. So likewise is the fact that in a *certain proportion of these* cases hæmorrhages have been found in other parts of the body—e.g., small extravasations in the floor of the lateral ventricles (F. E. Batten[2]), purpuric spots in the parietal pleura (F. W. Andrewes[3]), small hæmorrhages in the pleuræ, lung, epi- and peri-cardium (L. S. Dudgeon[4]). It is also noteworthy that adrenal hæmorrhage has been associated with a more general state of like nature in "hæmorrhage of the newly born," though the connexion in this latter case has not, as far as I know, been established.

These observations point to a fairly constant relation between hæmorrhage into the suprarenal medulla and the same condition elsewhere and our *present physiological data* point to the former as accounting for the latter. Dudgeon, Rivière, and others are inclined to regard suprarenal bleeding as of toxic origin, and it may be thus explained when associated with microbic diseases. I do not think that this interpretation is the only possible one. For my own case I am inclined to accept the view already quoted that strain or pressure during labour was the primary cause of the hæmorrhage with perhaps some assistance from inherent weakness of tissue related to the family history. The frequent failure to discover any micro-organisms in the suprarenals in these cases and the occurrence of "hæmorrhage in the newly born" would also seem to indicate that a toxic agent is not an indispensable antecedent.

Green Lanes, N.

A CASE OF INDICANURIA.

BY GORDON N. MONTGOMERY, M.R.C.S. ENG., L.R.C.P. LOND.,

HOUSE SURGEON TO THE DORSET COUNTY HOSPITAL.

As literature on this subject seems rather scarce a few notes on a case may be of interest.

The patient, a female, aged 32 years, is a servant at the above hospital. Her general health is good, except that she suffers at times from slight attacks of "petit mal." She says that she often has "trouble with her bowels," having to take pills sometimes to obtain an action. On March 2nd, having been constipated for several days, she took a pill of colocynth and hyoscyamus. This was her usual aperient. On the following day the bowels were relieved twice and she experienced some abdominal discomfort during the day. On this date the patient noticed that the urine was altered in colour and a specimen was brought to me. The colour varied in density during the following three days until March 6th, when it became much lighter, and on the next day it was quite normal. During these days the patient did her work as usual and felt quite well, except that she felt a little worried about the urine, which was coloured when passed. She had never passed urine like it before and has not done so since. The urine was of a dark blue-green colour, with a specific gravity of 1015; it was acid; there was no albumin or sugar. On adding a little chloroform to some urine in a test-tube the chloroform became a blue colour. When some urine was added to some boiling nitric acid a bluish ring was seen at the junction of the two liquids. There was no history of eating or drinking anything that she had not been accustomed to or of using carbolic acid in any form, or methylene blue.

Professor William Osler,[1] speaking of indicanuria, says: "The substance in the urine which has received this name is the indoxyl-sulphate of potassium, in which form it appears in the urine and is colourless. When concentrated acids or strong oxidising agents are added to the urine this substance is decomposed and the indigo set free. It is present only in small quantities in healthy urine. It is derived from the indol, a product formed in the intestine by the decomposition of the albumin under the influence of bacteria. When absorbed, this is oxidised in the tissues to indoxyl, which combines with the potassium sulphate, *forming* the above-named substance." Also: "It is not usually increased in constipation, although it may be present in large amount with no other discoverable cause. ...... Though, as a rule, the urine is colourless when passed, there are instances in which the decomposition has taken place within the body, and a blue colour has been noticed immediately after the urine was voided."

Dr. O. J. Kauffmann[2] writes: "Indican is derived from indol, which latter is formed in the intestine by bacterial decomposition of albuminous substances. A very little indican is commonly present even in the urines of healthy persons, but a considerable excess of the same, such as I show you in these specimens, is always accompanied by disturbed general health. We may, therefore, say that excess of indican in the urine is always associated with toxæmia and this toxæmia arises (with rare exceptions, in which the source is decomposing pus) from the intestinal canal."

The interesting points in this case, I think, are: (1) the deep colour of the urine; (2) the fact that it was coloured when passed; and (3) the circumstance that the patient was in good health.

Dorchester.

A CASE OF

APPENDIX RUPTURING DURING AN OPERATION AND AN ANALYSIS OF THE MEANING OF THE SYMPTOMS.

BY F. R. B. BISSHOPP, M.D. CANTAB., M.R.C.P. LOND.,

HONORARY CONSULTING PHYSICIAN, TONBRIDGE UNION INFIRMARY;

AND

JOHN D. MALCOLM, F.R.C.S. EDIN.,

SURGEON TO THE SAMARITAN FREE HOSPITAL, LONDON.

THE subject of the following history was a *delicate-looking* man of nervous type and 38 years of age. 14 years before the illness now recorded he suffered from an attack of internal inflammation for which mustard was applied to the right lower portion of the abdomen and during the last two or three *of the intervening years he occasionally felt* a slight discomfort in the same position which, however, never attracted serious attention. On July 9th, 1906, he did not feel well in the evening but had no pain. On the 10th he had breakfast as usual and the bowels acted. Immediately *afterwards and* throughout the day he felt slight pain along the top of the abdomen and, although getting about, he took no food except a little tea and a biscuit. He went to bed early and, later, had a dose of castor oil which made him vomit. Soon after this, about 10 o'clock at night, he was *suddenly* seized with intense pain like a hot and heavy ball deep down in the centre of the abdomen but not near the appendix. An alarming state of collapse followed and Dr. Bisshopp was sent for. When he arrived, about half an hour after the attack began, recovery had to some extent taken place, but there was still considerable soreness; the pulse was quick and the temperature was subnormal. A dose of less than an eighth of a grain of morphine was administered and gave relief. This was the only opiate given. On the next morning the patient was free from pain and he slept a great deal that day. He moved about his bedroom during the afternoon and seemed pretty well. In the evening he complained of pain in the appendix region, but no swelling was felt. On the morning of the 12th there were a well-marked protective contraction of the muscles over the cæcum and a slight fulness of the abdomen. After the 10th neither fæces nor flatus passed from the rectum, but there was no vomiting. The highest temperature was 99° F. It was thought that a perforation had occurred and the patient was seen in consultation by Mr. Malcolm at 5 o'clock P.M. on July 12th, 43 hours after the attack of pain and collapse occurred. He was then lying in bed quite comfortably without pain, with a normal temperature and with a quiet pulse beating 72 to the minute. There was a very little fulness of the abdomen and the muscles were less rigid but still resistant over the appendix. There was no defined swelling.

---

[2] Transactions of the Pathological Society, 1893.

[3] Ibid.

[4] American Journal of the Medical Sciences, 1904.

[1] Principles and Practice of Medicine, p. 620.

[2] THE LANCET, July 14th, 1900, p. 75.

At this time there was nothing to indicate that the patient's condition was a serious one, but it was considered wise to operate at once. The preliminary pain, the acute collapse, the subsequent quiescent state of the intestine, the fulness of the abdomen, and the continued resistance over the cæcum, together with the absence of inflammatory symptoms and of a defined swelling, led us to this decision. Mr. Malcolm thought that the appendix was in part gangrenous. Within an hour the patient was anæsthetised by Mr. G. Roberts and the abdomen was opened. On puncturing the peritoneal sac with the point of a knife a few drops of pus-like matter escaped, and on extending the incision there was a considerable flow of fluid which would be described more accurately as a turbid serum than as pus and which was free in the peritoneal sac. It was not offensive. The appendix lay behind the cæcum and was very lightly attached to some of the surrounding structures by recent adhesions which were separable by a mere touch of the fingers. It was *not ruptured when first seen, but the traction necessary to* bring it forward caused a drop of opaque whitish material to escape through a small opening in its wall. The rupture evidently took place in consequence of the manipulation. The appendix was removed, and the pelvis, the right loin pouch, and the retro-cæcal region were drained by rubber tubes and gauze tampons, the surfaces of the wound in the abdominal wall being drawn together by sutures as much as the method of treatment would allow. The patient bore the operation well; his pulse was rapid during its progress but soon quieted down after he was replaced in bed.

The highest temperature following the operation was 100·6° and the quickest pulse was 90. There was a profuse discharge of serous fluid during the first 30 hours. Between the second and fourth days the drainage mechanism was all removed except a superficial gauze packing. The tube and gauze in the right loin became distinctly offensive, but they were first shortened and then taken out with the others which were free from odour. After about 48 hours flatus began to be expelled from the rectum, the abdominal fulness gradually subsided, and the bowels moved at the end of three days. There was a very decided yellow discolouration of the skin, increasing until the third morning and then passing off. The subsequent history was one of uninterrupted recovery, the skin edges, which at first were necessarily widely apart, being completely healed at the end of six weeks. The most recent accounts of this case show that the patient's health is completely restored. The scar has held very well, especially if the mode of its formation is considered; it only bulges slightly.

After being nearly a month in spirit the appendix had a diameter of just under half an inch in its distal two-thirds, whilst that of the proximal third was a quarter of an inch. There was a perforation about the middle of the thickened portion, nearly as far as possible from the meso-appendix and about a twelfth of an inch in diameter. On slitting up the canal it was seen that its lumen at the junction of the narrow and the thicker part was almost obliterated. The figure is a microphotograph of part of a section showing the perfora- tion. The Clinical Research Association reported that "this appendix shows inflammatory changes most marked around the perforation, less towards the tip, and less still near the cæcal end. Around the perforation all the coats are infiltrated with leucocytes and there is much proliferation of lymphoid elements. At the constriction the mucous membrane seems to have almost entirely disappeared, only one or two patches of lymphoid tissue remaining."

Remarks by Mr. MALCOLM.—There is no doubt that in this case there was an increasing contraction of the lumen of the appendix which probably began as a consequence of a previous inflammation 14 years before the operation. As the canal became almost closed there were attacks of discomfort, hardly amounting to pain, caused by temporary distensions of the portion of the appendix beyond the stricture. These attacks were little noticed, not being accompanied by any obvious symptoms of constitutional disturbance.

Clearly some new factor was added to the case in the illness during which I operated, and the phenomena observed seem to be explained most fully by, and also very strongly to support, the view which I have already advocated[1] that in the appendix, as in the stomach and duodenum, a gangrenous patch may form *without any preceding symptoms.*

I believe that before this patient felt any pain on July 10th the perforation shown in the figure, or at least the outer part of it, was filled with tissue which suddenly became *gangrenous.* In other similar cases I have discovered such patches *in situ* and unseparated from the living tissues when the abdomen was opened.[2] This change gave rise to no symptom, except a doubtful malaise, until some degree of tension arose within the appendix. Then the traction on the living structures attached to the dead patch caused a definite pain. The dose of castor oil, by inducing movements, straining, and pressure on the appendix, increased the tension within it; the pain consequently became agonising and *symptoms of collapse followed.* That the pain was not at once referred to the appendix region is a very common observation in these cases. A gangrenous patch does not, however, lose all strength or become separated immediately on its formation, and in the case recorded the recently dead tissue was still of firm texture and intimately attached to the surrounding living structures when the acute attack occurred. Hence a rupture did not then take place. The contents of the appendix partially escaped into the cæcum, as they had always done before, and relief was obtained. The dose of morphine given and the quietness enjoined helped to prevent the development of further evidences of mischief for a time. The pain was comparable to that caused by the act of defæcation when an anal fissure exists. In such circumstances intense pain and even fainting may be induced, but when the stool has passed, in a short time, especially if morphine is given, the pain ceases until the anus is again distended.

Reproduction of microphotograph showing the perforation in the appendix wall and an obvious loss of tissue.

When a gangrenous patch develops in a portion of the wall of the intestine micro-organisms must sooner or later pass through it to the peritoneum, and the further history of the illness depends chiefly on the nature of those escaping. In the case above recorded those which found their way into the peritoneal sac induced an exudation that was probably a clear serum at first but was distinctly turbid at the time of the operation and would have become truly purulent later on if interference had been delayed.

The micro-organisms in this particular case were not very injurious, but either those first *escaping, or perhaps others* of a more virulent type which followed, had a sufficiently irritating effect to cause a quiescent state of the bowel and a tendency to its distension. Moreover, when the abdomen was opened the gangrenous patch was ready to separate and a rupture did actually occur during the operation. It is *therefore certain that, if surgical* treatment had been postponed, the evidences of a spreading peritonitis would, in a very few hours, have been much more pronounced, the appendix would have ruptured, and the gravity of the patient's condition would have increased enormously.

---

[1] Appendicitis and Gangrene of the Vermiform Appendix considered as Separate Diseases, Transactions of the Royal Medical and Chirurgical Society, vol. lxxxix., and THE LANCET, July 28th, 1906, p. 213.

[2] Loc. cit., Cases 7 and 8.

The success of the operation and the comparative freedom from danger were mainly due to Dr. Bisshopp's prompt recognition of the necessity for surgical interference. Another very great danger was escaped by the patient's unquestioning decision to follow the advice given. An emergency operation is seldom performed when the immediate symptoms appear so little urgent as they did in this case, and a hesitation to accept the treatment recommended would have been very natural. The patient was urged to acquiescence by a fear of a return of the pain.

The responsibility of recommending operative interference in such cases is often very great, but as our knowledge of the changes taking place increases we shall be able to advise with more precision. The view that in the appendix, as in the stomach wall, a piece of tissue may die and may remain in its normal position for a time without causing symptoms of any kind facilitates the diagnosis by offering a rational explanation of the symptoms, and I operated with the greatest confidence that a gangrenous patch existed in the case under discussion. Without holding this view it is possible to recognise the necessity for operative interference because after similar symptoms rapid death has followed. But when, as in the case recorded, there is an illness of not less than between 50 and 60 hours' duration, at the end of which time a gangrenous patch in the wall of the appendix is found to be just about to give way and when the highest recorded temperature is only 99°, the explanation that the conditions observed are the effects of an inflammation is inadequate. The alleged cause of mischief appears to be absent. It is true that evidences of inflammation were found in the microscopic sections of the appendix, but this tube must have been in a chronic state of irritation for some years on account of the tightening constriction, and the infiltration of leucocytes around the perforation may be fully explained as the consequence of the presence of the dead tissue.

I have published other cases[2] in which a similar absence of evidences of inflammation has been observed in association with a gangrene formation, and if we consider those cases to which the term explosive or fulminating appendicitis has been given much may be said in *favour of the view that* the illness depends upon a gangrene formation which has caused no symptoms until perforation occurred by separation of the dead part. Such cases are often characterised at first by symptoms of shock and by collapse, which are easily accounted for as the results of perforation but not as those of an acute inflammation. The inflammatory symptoms which do arise later may often be most satisfactorily interpreted as the effects of the presence of a gangrenous patch or of the discharge of the contents of the bowel into the peritoneal sac.

The cause of a gangrene formation in the appendix, as in the stomach, is obscure, but in many cases, as in the one related in this paper, the death of tissue is certainly not due to a sthenic inflammation and is not accompanied by immediate symptoms.

ROYAL SOCIETY OF MEDICINE.

MEDICAL SECTION.

Discussion on the Administration of Tuberculin and other Vaccines by the Mouth, together with (a) Normal Saline Solution and (b) Fresh Horse Serum.

A MEETING of this section was held on May 26th, Dr. S. J. GEE, the President, *being* in the chair.

Mr. E. C. HORT said that Dr. A. Latham, in his paper on the Administration of Tuberculin and other Vaccines by the Mouth, together with (*a*) Normal Saline Solution and (*b*) Fresh Horse Serum,[1] had discussed questions upon which he (Mr. Hort) had been engaged for 12 months in attempting to answer. He ventured, therefore, to contribute to the discussion by briefly referring to his own work on the subject which to some extent confirmed the results arrived at by Dr. Latham. Dr. Latham's investigations, though commenced at a more recent date than his (Mr. Hort's) formed an absolutely independent inquiry of his own. As regards the internal administration of normal horse serum, he had in the last 14 months been directly responsible for the administration of more than 50,000 cubic centimetres in over 150 cases of different diseases, details of which would shortly be published. His experience was as follows: 1. Its action when given internally was more restricted than when applied locally. Its mode of action in the former could at present only be indicated by its more easily observed action in the latter. In that it seemed to combine a stimulant action with the paralysing action that it could be demonstrated *in vitro* and *in vivo* to exert on autolytic and heterolytic enzymes. 2. It might be given by the mouth for weeks in daily doses of from 30 to 40 cubic centimetres with impunity but it must be fresh and sterile and should be given directly after meals during digestion. If those conditions were observed the collapse, serum rash, pyrexia, and other by-effects noted by Dr. Latham would not occur. 3. In such generally infective conditions as pulmonary tuberculosis and pneumonia it was apparently of little value. Dr. Latham's suggestion of giving it with tuberculin might prove of benefit but of that he had had but little experience. 4. If given internally many cases of so-called simple anæmia showed a rapid rise of hæmoglobin and corpuscular content, though in pernicious anæmia it was useless. 5. In hæmoptysis, purpura, hæmophilia, and the hæmorrhage of enteric fever it was often of material benefit. 6. When applied locally in the form of constant dressings in such chronic conditions as local tuberculosis and staphylococcal infections it gave good results. In cases of mixed infection of those two organisms he had found it good practice to attack the staphylococcal infection first by administering the appropriate vaccine by the mouth. 7. In such conditions as chronic gastric and duodenal ulcer, ulcerative colitis, extensive varicose ulcer, bedsore, &c., it was with few exceptions of high value. It might appear that the action of normal horse serum on conditions not obviously bacterial was outside the scope of a discussion on immunity. But one of the many functions of the serum of an individual and of his cells seemed to be the restraint exerted on the autolytic action of his own enzymes. In many lesions—as, for example, in all kinds of ulceration not primarily dependent on bacteria—the phenomena of ulceration might be due to an absence of such restraint: in other words, to a breakdown in the mechanism of immunity against such enzymes. It was beyond dispute that the normal serum of many animals, including man, and notably of the horse, had strong antitryptic and anti-autolytic power. By administering serum, as in the cases referred to, they were, of course, merely transferring that protective body to the seat of cell destruction. The clinical effects were significant and might explain many hitherto unexplained diseases, of which non-bacterial ulcerations of all kinds seemed to be a good example. In bacterial lesions the effect of the serum appeared to be, amongst other things, stimulation to repair and inhibition of bacterial proteolysis. This antitryptic power of serum was becoming well known. The work of Cathcart, Baer, and later Koltschmann and Müller showed that the anti-enzyme was tied to the albumin fraction. It appeared from the work of Dr. F. L. Golla that its inhibitory power underwent variation in different diseases. The satisfactory results which he had obtained with normal serum in many forms of proteolytic cell destruction had led him to attempt to get a serum prepared with this antitryptic power increased. In that he owed much to the work of Martin at the Lister Institute and to Dr. Golla who informed him that serum so prepared had a high antilytic valency. It might be prepared in two ways, either by subtracting from serum the globulin moiety, which favoured proteolysis, or by increasing the relative amount of albumin present. Such had now been prepared and the difficult problem of at the same time preserving the stimulins had also been apparently solved. The serum stripped of its globulin he had labelled antilytic serum A; the serum in which albumin content had been increased and in which the globulins had been left intact with the stimulins and other antibacterial bodies he had designated antilytic serum B. The first was for internal use; *the second for local. As regards the* oral use of tuberculin and other vaccines by the mouth he had only the evidence of some 20 recent cases of his own, *mainly of* staphylococcal infection, *to offer. These included cases* of pustular eczema, suppurating sinuses and infected ulcers of the tongue and mouth, and a few of surgical tuberculosis. He had treated most by vaccines by the mouth and local applications of serum. At present he could only say that the results were encouraging.

---

[2] Loc. cit.

[1] THE LANCET, March 28th, 1908, p. 934.

Dr. **HECTOR MACKENZIE** said that with regard to staphylococcic infections he was satisfied that they had in vaccine treatment by the mouth a powerful remedy and he had seen the most remarkable results in long-standing cases. Concerning the administration of tuberculin he was still in doubt. He had seen similar results from other methods of treatment in cases like those described by Dr. Latham. Until they had a considerable number of cases treated by tuberculin they were not justified in drawing conclusions. His impression from the cases of *tuberculosis of the lung* under his care treated by tuberculin and serum was that favourable results were not observed in those cases which had not been doing well before the tuberculin treatment was started. He had treated a number of cases of tuberculous glands with tuberculin given three times a day by the mouth. The glands softened and became smaller and gradually subsided. He considered that in pulmonary tuberculosis much work had to be done before the matter was understood. The *results were encouraging and the treatment* was worthy of further trial, so that the best time to give tuberculin might be settled and the proper dose. Observations as to the relation of the opsonic index to the temperature were of value, because if the treatment depended on observations on taking the opsonic index then the progress of the method would be impeded, for it would be impossible to regulate the treatment by *opsonic index only.*

Dr. A. G. **AULD** thought that the cases brought forward by Dr. Latham were too few and inconclusive; they did not furnish any reliable guide for the medical practitioner.

Dr. H. D. **ROLLESTON** said that from what he had seen at St. George's Hospital there was a great future for the treatment. He described cases of gastric ulcer in which horse serum by the mouth had been successful, but *he contended* that though there was no doubt that horse serum did stop hæmorrhage *nevertheless the serum should be standardised.*

Dr. H. J. **JOHNSTON LAVIS** said that the successful treatment of tuberculous patients by means of meat juice might be explained by the fact that tuberculous meat had been accidentally selected.

Dr. S. **VERE PEARSON** related a case of a patient who had tuberculous disease of the right kidney in which since tuberculin *had been given by the mouth the patient had* been much freer from pain than before the treatment and the general condition had improved. He described another case of spinal caries in which relief from pain had been afforded by the treatment. He narrated the details of a case in which there were acute signs *of pulmonary tuberculosis* and in which for six months there had been constant *fever that persisted in spite of every remedy* being tried, but when the patient was given tuberculin and horse serum the temperature fell within three weeks' time and the pulse-rate became lower.

Mr. W. **STUART-LOW** said he thought that he would not be contradicted when he claimed to have been *the first to* employ fresh animal blood serum locally in *the treatment of* wounds. He had first used it at the Central Nose, Throat, and Ear Hospital as a dressing in the radical mastoid operation in a series of cases of chronic suppuration of the middle ear. This was two years ago, and in THE LANCET of May 4th, 1907, he had published a preliminary account of his results. This horse serum was *supplied by* Messrs. Burroughs, Wellcome, and Co., except in his earlier series of cases in which he had used serum obtained from the butcher, when the serum of lambs and sheep was employed. He now made use of fresh horse serum in a routine way in mastoid operations. The results had been very good and *gratifying to the* surgeon and the patient, as in this way the average time that the patients were detained in the hospital had been shortened to five days. With horse serum as a dressing the most *fœtid* and septic cases could have a thorough and extensive operation performed, and the risks of dangerous sequelæ such as septic meningitis could be minimised. His practical experience with horse serum led him to believe that there was a great future for it in surgery, and particularly in ear surgery.

Dr. **LATHAM**, in reply, said that it had been proved that animals could be immunised by feeding them on an *emulsion of dead tubercle bacilli provided it* was administered on an empty stomach but if given with food no immunity resulted. That was *conclusive that it was not right to give* vaccines together with food. As far as the opsonic index could be taken as a guide, better results were secured by giving serum on an empty stomach than with food. In his opinion the cases referred to by Dr. Mackenzie in which the results of the treatment were not satisfactory were cases in which it would have been a miracle if a cure had taken place. He admitted *that in those cases* where coughing caused auto-inoculation the treatment did not show the satisfactory results described in the cases which he had put forward. Answering a question from Dr. R. H. Hodgson, Dr. Latham said that in regard to the relation between exertion and the temperature in phthisical cases there was no doubt that exertion produced a rise in the temperature if undue auto-inoculation occurred. It was possible to treat phthisical patients by exercises and to utilise their own auto-inoculation *to secure immunity, but the amount of exercise* permitted had to be regulated carefully according to the temperature. In cases of acute pulmonary tuberculosis for the opsonic index to be of value it ought to be taken three or four times a day. In cases of chronic pulmonary tuberculosis *he considered that* the treatment could be carried out without the opsonic index, for in those cases the opsonic index *could be gauged by a consideration* of the clinical symptoms and the temperature of the patient.

ODONTOLOGICAL SECTION.

Extraction of an Upper Wisdom Tooth.—Pyorrhœa Alveolaris.—Heredity and Dental Disease.

A MEETING of this section was held on May 25th, Mr. J. **HOWARD MUMMERY**, the President, being in the chair.

Mr. W. **RUSHTON** gave as a communication Some Notes on the Extraction of an Upper Wisdom Tooth.

Mr. J. G. **TURNER** read a paper entitled Clinical *Notes* on Pyorrhœa Alveolaris. He found that clinically fully 50 per cent. of cases of pyorrhœa were furthest advanced in the molar region—i.e., it had commenced in that part. He had noted in the mouths of people who used their toothbrushes pyorrhœa absent at the labial gum margin of incisors, canines, and premolars, but well advanced elsewhere, where the toothbrush less readily reached. In respect of its point of origin, pyorrhœa was clinically a dirt disease, like dental caries, *the dirt* being bacteria with or without food débris, and stagnation being *its* complement. The general age of onset, early adult life, was a point rather against Mr. Goadby's milk-borne theory, since raw milk was then but little drunk. Mr. Turner drew attention to the fragility of the affected teeth, which *led to* an unusually large average of fractured apices in extraction of *pyorrhœic teeth. The possible relationship* of acute pyorrhœa and ulcerative stomatitis was alluded to.

Mr. **STANLEY P. MUMMERY** read a paper on Heredity and Dental Disease. He first dealt with the neglect shown by the medical profession generally towards the important subject of heredity and *stated it as his belief* that dental caries in common with many other diseases owed *its origin* as well as *increasing prevalence* to hereditary *factors. The pathology of dental caries* had already been worked out by the late Dr. W. D. Miller, but its etiology still remained obscure. Disease in general was to be regarded as an undesirable variation from the normal, and as such was *kept in check by the law of the* survival of the fittest and consequent elimination of the unfit, including those susceptible to disease. In this way a race was gradually rendered immune to a particular disease *to which it might* become exposed. Dr. Archdall Reid had written on this subject and had *shown* how in the case of malaria races which had long been exposed to its infection, such as the West African negroes, had become gradually immune to the disease, not owing to the inheritance of acquired immunity, but owing *to* extermination of the more susceptible individuals, breeding only taking place among those who were less susceptible and *who therefore* survived. Among civilised races, however, this selective action of nature was prevented by modern science from exerting any influence on certain diseases, such as insanity and dental caries. In the case of insanity the insane were now treated with such skill that a large proportion recovered sufficiently to leave the asylums, when they could marry and have large families, many of whom inherited this insane diathesis; thus the real increase of insanity in modern times was the same with dental caries. Owing to the soft, easily-digested food of modern diets the full set of teeth was not necessary for mastication. Hence defective and carious teeth did not affect the individual to the extent of preventing him from having large families, as would be the case with savage men living on hard food needing thorough mastication. Thus by the absence of the action of natural selection and the consequent breeding among the unfit the number of susceptible individuals rapidly increased until now nearly every child was born of susceptible parents. The main cause of the modern increase of dental caries was therefore due to the increasing susceptibility in the teeth themselves, which was the fault of the absence of the action of natural selection in weeding out the more susceptible individuals.—Mr. F. J. BENNETT, Dr. J. SIM WALLACE, Dr. NORMAN G. BENNETT, Mr. K. W. GOADBY, and Mr. H. BALDWIN took part in the discussion.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A MEETING of this society was held on May 20th and partook of the nature of a dermatological clinique, Dr. JAMES RITCHIE, the President, being in the chair.

Dr. NORMAN WALKER gave a *résumé* of his work in the skin department of the Royal Infirmary during the last 16 months with special reference to groups of interesting cases and to those subjects at present attracting most attention. The experience of the department showed that Alopecia Areata was exceptionally prevalent in Edinburgh but the statistics required much more prolonged examination than he had yet been able to give them for coming to any conclusions as to possible epidemics of this disease. It was, however, remarkable that compared with the available statistics of London and Glasgow the proportion of cases of alopecia in Edinburgh was very distinctly greater. He brought before the meeting a small detachment of the many cases of Favus at present under treatment with the view of demonstrating how hopeless it was to expect satisfactory results in those placed in the social circumstances of the patients and he hoped that the matter would be taken seriously up by the new medical officer of health of Edinburgh. The disease was very common in Edinburgh; while it was easily cured amongst the better classes it was really a terribly incurable disease in the lower classes. Cases often required treatment during three or four years, and in one case the hair of the scalp had been removed by x rays on eight occasions in an endeavour to cure the disease. His statistics of Herpes Zoster showed quite clearly the epidemic nature of this disease, though the numbers were probably misleading, as many cases were treated in dispensaries, at home, and in the medical waiting-room. Impetigo showed striking variations, as was indeed to be expected with so eminently contagious a disease. Lupus Erythematosus occurred in the proportion of 1 per cent. of his cases. The most interesting fact to record in connexion with this was the reaction to Pirquet's method of vaccination with tuberculin. He had only recently had the opportunity of trying this, but in three cases of lupus erythematosus one showed the reaction and the other two were definitely negative. He said that he had not time to go into the matter, but these facts were interesting to those who maintained that lupus erythematosus was not a tuberculous disease. He next demonstrated a number of cases of Lupus Vulgaris which had been under treatment in the skin department for many years and claimed that in all forms of treatment the most essential element was perseverance. The administration of thyroid gland extract helped in the removal of the complications of lupus but it did not of itself cure the disease. He showed one case and a cast of another of Lupus Cancer. Both had been treated by erasion and the application of caustics with apparently complete success, and in one case a limb was saved to a young woman. He remarked that he believed that the disrepute into which the caustic treatment of carcinoma had fallen was due to timidity in its use. It was generally taught that carcinoma which occurred in young persons was of special virulence but he had not found this to be the case in those patients who suffered from lupus carcinoma. Nearly all of the patients who suffered from Molluscum Contagiosum attended one of the Edinburgh public baths. He demonstrated one case and a number of casts by Dr. Low or his assistant of Ringworm of the Nails, five cases of which had come under his notice in the last four months. Some of these had been unrecognised during many years and none had any evidence of the disease on the body. Of the 2500 cases with which he was dealing 62 had been cases of Rosacea. He referred briefly to his belief that this disease was generally seborrhœic in origin and that indigestion did not play the all-important part which many attributed to it. Careful inquiry was made in each case and only five of them were noted as suffering from indigestion, while in seven others there were headaches, constipation, and the like noted. He demonstrated a very satisfactory case from this point of view in the person of the patient who formed the subject of the illustration in the new edition of his book and who after two months' treatment showed no sign of the disease. In dealing with Sycosis he gave his experience of the vaccine method. He demonstrated the case of a man who had been treated by ordinary methods without success and who had been threatened with loss of his employment but who had almost entirely recovered under injection of vaccine prepared from his own staphylococci. In this connexion he referred to the use of tuberculin in lupus which he had found most valuable. The number of cases under his care made it impossible for the index to be taken in each, but he had found that a dose of 1-15,000th of a milligramme every four weeks had been followed by excellent results. He briefly referred to the number of cases of ringworm, 200 out of the 2500 cases, and while admitting the merits of the new x ray treatment he had not found that it was so invariably successful as had been sometimes claimed. Lastly, he demonstrated the cast of a case of Actinomycosis as it appeared when it came under his care six months ago; the patient had entirely recovered under the administration of very large doses of iodide of potassium.

Dr. F. GARDINER showed several cases which were chiefly noteworthy from the point of difficulty in diagnosis. 1. A girl, aged 18 years, who suffered from what at first glance appeared to be a typical Pityriasis Rosea, the patches being slightly raised, scaly, and salmon coloured. The lesions were situated on the front and back of the chest and trunk but there was no Herald patch, and in addition the limbs were affected, whilst the scalp showed dry seborrhœa, while two favourite seats of seborrhœa (behind the ears and in the axillary folds) were sites of the eruption. In spite of a recent history (14 days) and no previous attack he inclined to the diagnosis of seborrhœa. 2. A case of Erythema Multiforme simulating secondary syphilis. It had occurred two months after the appearance of the primary sore, one week after the administration of mercury up to the limit of salivation, and it had continued a fortnight after the administration of the mercury had been given up. The eruption was itchy and affected the arms, the legs, and the face. Salicin was recommended. 3. A case of Erythema Scarlatiniforme, universal and coming on one month after stopping the use of copaiba for gonorrhœa. It had all the characters of a drug rash. 4. A case of Favus of the Scalp closely resembling tinea, and in which there were broken hairs, grey scales, no scutula and no mousy odour. It was diagnosed by the microscope. 5. A patient who had been x-rayed four years previously for Tinea Capitis. Complete epilation had then occurred and there was a splendid growth of hair now present. She had developed a fresh attack, but this was of the large-spored type. 6. The mother of this last child suffering from typical Alopecia Areata. Microscopic examination had shown no trace of fungus. 7. Alopecia of the Scalp and Scarring of the Face following on a recent attack of small-pox. 8. Four cases of Rodent Ulcer under X Ray Treatment.

Dr. R. CRANSTON LOW exhibited: 1. A case of Pemphigus Foliaceus in a woman, aged 53 years. The disease had commenced 11 years ago and at first the eruption closely resembled dermatitis herpetiformis. Three years ago the affection became generalised and exfoliating. The general nutrition was good. The patient had been treated with a vaccine made from the contents of the blebs and with a marked improvement. 2. A case of Early Mycosis Fungoides in a woman, aged 52 years. The eruption had commenced on the palms and soles 14 months ago and resembled a case of psoriasis. Since this time numerous red, scaly points had appeared until nearly the whole of the body was affected. About a month ago, on the backs of both feet, small tumour-like masses had appeared. The patient was being treated by the x rays. 3. Kerion of the Scalp due to the small spore fungus in a boy. 4. A case of Rupia which was under the care of Mr. Alexander Miles in the Lock wards. The eruption showed the typical limpet-shaped crusts. On the face there were other crusted and oozing lesions as well as on the body and limbs. The patient's husband had been treated in the Lock ward in December, 1907, for a primary sore.

Dr. J. S. FOWLER showed a case of Urticaria Pigmentosa in a child.

Mr. HENRY WADE demonstrated (1) a remarkable case of Hyperkeratosis Plantaris from a lunatic patient, and (2) a case of Mycetoma.

Reviews and Notices of Books.

A Manual of Venereal Diseases. By Officers of the R.A.M.C. Oxford Medical Publications. London: Henry Frowde, Oxford University Press; and Hodder and Stoughton. 1907. Pp. 282. Price 5s. net.

THIS work gives an account of the information contained in the reports made to a sub-committee appointed by the Army Medical Advisory Board to consider the question of treatment of venereal disease in the army. It is intended to act as a convenient manual for the use primarily of the army medical officer to assist him in his daily work in the prevention and treatment of venereal disease. Sir Alfred Keogh in his introduction, after alluding to the effect of improved hygiene on the gradual decline of venereal disease in this country, as contrasted with the absence of this decline in India and the Colonies, where sanitary control is more difficult and complicated, alludes significantly to the low incidence of these affections in continental armies, which he rightly says is due mainly to systems of legislative control, and he points out how the two great Anglo-Saxon States, whose attitude to legislative control is similar, have a far larger incidence of venereal disease in their armies than any other country. A striking instance of this occurred not many years ago in one of our hill stations in India. Here a diseased prostitute was living in a hut about ten yards outside cantonment limits. She was visited daily and infected daily the soldiers of the garrison, yet at that time nothing could be done by the officer commanding the station.

Lieutenant-Colonel C. H. Melville, R.A.M.C., contributes the section comprising the history, statistics, and invaliding from venereal diseases. Taking the troops stationed in the United Kingdom, there has been a steady fall in the invaliding-rate for syphilis since 1902, due probably to the introduction of the treatment by the injection of mercury, with which the name of Colonel F. J. Lambkin, R.A.M.C., is so honourably associated. Thus since 1905 no men of the Brigade of Guards have been invalided for syphilis since this method was practised. With regard to the army in India we find an increasing rate of admissions from 1880 to 1888, the year in which the Contagious Diseases Act was abolished in India. Then the admissions rapidly increased, attaining their maximum between 1894 and 1896, since when the fall has been rapid and continuous, due to the introduction of the Cantonment Act of 1897. Lieutenant-Colonel Melville gives a *résumé* of the measures adopted by the various foreign countries to cope with this evil and the more stringent rules in these countries are shown by a comparative statement of the incidence of venereal diseases in the several armies to effect their purpose admirably; for example, the admission per 1000 in the German army in 1900 was 17·8 as contrasted with 93·4 in the British.

The subjects of clinical pathology and bacteriology are contributed by Colonel W. B. Leishman, R.A.M.C. The history of the research for the micro-organism is admirably given, the account of the spirochæta being one of the best in the English language. Major C. E. Pollock has contributed the section on the clinical course and treatment. He considers the following practical points as regards (1) the commencement of treatment, which he holds should be instituted as soon as, but not before, the diagnosis of syphilis has been made; (2) the period for the administration of mercury is considered to be two years, provided it is thoroughly carried out; (3) the general scheme of treatment, whether continuous or intermittent, the latter being held to be the most advantageous in the case of the soldier; and (4) the methods of administering mercury, whether by the mouth, by the skin, or by injection. The last is undoubtedly the best from an army point of view, and as this is the case the reader will find its technique laid down with precision as regards all its parts.

The volume concludes with the subjects of soft chancre and gonorrhœa and has several valuable appendices. In conclusion, we can say that this manual admirably fulfils the purpose for which it was compiled.

American Practice of Surgery: A Complete System of the Science and Art of Surgery by Representative Surgeons of the United States and Canada. Editors: JOSEPH H. BRYANT, M.D., LL.D., and ALBERT H. BUCK, M.D., of New York City. Complete in eight volumes. Profusely illustrated. Volume III. New York: William Wood and Co. 1907. Pp. 775. Price $7.

THE third volume of this elaborate system of surgery deals with the important subjects of injuries and diseases of bone and injuries and diseases of joints, in addition to a comparatively short section on poisoned wounds, including the bites and stings of animals and insects. This section on poisoned wounds treats of many animals the likes of which are not met with in this country but the accounts are good. Erysipelas comes next. The author, Major C. F. Mason, surgeon in the United States Army, holds that the streptococcus erysipelatis is identical with the ordinary streptococcus pyogenes; but he gives no hint that in recent years a differentiation of various species of streptococci has been possible and that in all probability the streptococcus of erysipelas is specifically distinct, even though it is capable of causing septicæmia. Accounts of various infected wounds follow, such as anthrax, tetanus, and actinomycosis; they need no comment. Dr. G. G. Rambaud of New York has contributed the article on Hydrophobia; it is very good and an excellent plate showing "Negri bodies" is given.

Dr. Duncan Eve of Nashville has written the section on Fractures. In the description which is given of Colles's fracture no mention is made of the fact that skiagrams have shown that in a large proportion of the cases there is also a fracture of the neck or styloid process of the ulna. It is useless to say (p. 131) in speaking of the treatment of fracture of the shaft of the humerus "Middeldorpf's triangle and Vulpius's aluminium splint are often applied in Germany for fractures of the shaft of this bone," without any account of these splints. Middeldorpf's triangle is certainly worthy of a fuller description as many surgeons consider it to be the best form of treatment for this fracture. Dr. T. Turner Thomas of Philadelphia has supplied the article on Pseudarthrosis and the various modern methods of treatment are detailed. The article on Inflammatory Affections of Bones is by Dr. George A. Peters of Toronto, and that on Non-Inflammatory Affections of Bones is by Dr. Roswell Park of Buffalo; both are excellent. Dr. J. Shelton Horsley's paper on Syphilitic Disease of Bone seems to be complete and the treatment is judicious. The following sentence, however, may be easily misunderstood: "The best ointment is one prepared from the following formula: Compound tincture of benzoin ʒss.; mercury and lanolin each ℥j." It is highly probable that the author intended to write "mercury ointment" in place of "mercury."

Tumours originating in Bone are dealt with by Dr. Channing C. Simmons of Boston, Massachusetts, who supports the idea that ivory exostoses arise from persistent fragments of the chondrocranium, though no cartilage is ever found in connexion with these exostoses. He gives no reason why they should not arise from the periosteum, by far the most probable source. The article is very good and is well illustrated. We are glad to see that an account is given of echinococcus disease of bones, for many text-books hardly mention it. The name of the collector of cases of this disease should be Targett, and not Taggett.

Dr. C. F. Painter of Boston has undertaken the subject of Chronic Non-tuberculous and Non-traumatic Inflammations of Joints. He has given a very good account of the atrophic and hypertrophic forms of arthritis. It seems a pity to call "loose bodies" in a joint "foreign bodies," for it leaves us with no convenient name for a true foreign body in a joint. Syphilis of joints is a subject often much neglected; it is well treated here. Dr. Alexander Primrose of Toronto has contributed the article on the very important subject of Tuberculous Diseases of Bones and Joints. It occupies more than 160 pages and is quite a treatise on the subject. Especially good are the sections on treatment, for they are very practical. The concluding chapter in this volume is on Wounds of Joints, by Dr. John C. Oliver of Cincinnati. Dr. Oliver includes all forms of injury under the title "wounds." He speaks of washing out an infected knee-joint but he does not tell the reader what solution should be employed.

Handbuch der Tropenkrankheiten. (*Handbook of Tropical Diseases.*) With contributions by Dr. A. BAELZ, Fleet-Surgeon P. W. BASSETT-SMITH, R.N., Dr. P. VAN BRERO, Dr. C. L. VAN DER BURG, Dr. A. CALMETTE, Dr. CARROLL, Dr. A. EYSELL, Dr. D. DENNIG, Dr. P. KRAUSE, Major W. B. LEISHMAN, R.A.M.C., Professor Dr. A. LOOSS, Dr. MAX LÜHE, Dr. W. G. MACCALLUM, Dr. L. MARTIN, Dr. K. MIURA, Dr. A. PLEHN, Dr. R. PÖCH, Dr. F. RHO, Dr. R. RUGE, Dr. TH. RUMPF, Dr. L. SANDER, Dr. A. VAN DER SCHEER, Dr. K. SCHILLING, Professor Dr. G. STICKER, and Dr. H. ZIEMANN. Edited by Dr. CARL MENSE. Third volume. With 315 illustrations. Leipsic: J. A. Barth. 1908. Pp. 818.

THIS is the third and concluding volume of this admirable treatise on tropical diseases, the two former volumes of which we have already reviewed. Judging from the names of the authors of the various chapters the reader will be led to expect articles of no ordinary value. Nor will he be disappointed. The three volumes of Dr. Mense's "Diseases of the Tropics" constitute indeed the most valuable treatise on tropical diseases extant. To Dr. R. Ruge is intrusted the subject of amœbic dysentery. Herein the student will find the characteristics of the various amœbæ succinctly described and illustrated with beautiful plates: the pathological anatomy and symptomatology are exhaustively given together with the treatment. Dr. W. G. MacCallum treats of tropical liver affections, of congestion and suppuration. The author believes in the connexion between dysentery and liver abscess. The localities into which the latter may burst are noted and a good description is given of the symptoms. We fail, however, to find any mention of the excellent method of treatment, that has proved so serviceable, instituted by Sir Patrick Manson. Dr. Max Lühe writes of the effects produced by the various protozoal organisms, the section on the trypanosomata being the most complete exposition with which we are acquainted. The whole subject is dealt with in 200 pages and is illustrated by some very artistic plates. Dr. Hans Ziemann writes on malaria; in the historical description of the discovery of the cause of this affection Professor Ronald Ross, we think, does not receive sufficient credit. An excellent plate is given portraying the evolution of the parasite. This article includes all that is known up to date, whilst the various methods of treatment are fully described. It is enriched by a full bibliography and by excellent drawings. Blackwater fever is described by Dr. Ziemann. The author holds that this disease depends on two factors—first, the presence in the patient of a disposition developed after a longer or shorter infection with malaria, and, secondly, the presence of certain factors provoking it, such as malaria alone, malaria plus quinine, quinine alone, or any condition impairing the resistance of the body. In the treatment the author states that the main considerations are to keep up the strength of the circulation, to remedy the tendency to suppression of urine, and to stop the hæmocytolysis. Our own countryman, Major W. B. Leishman, R.A.M.C., treats of kala-azar, a subject on which he is a well-known authority. The various views of this affection are given and the characteristics of the Leishman-Donovan organism are described and well illustrated. Dr. C. Mense describes trypanosomiasis and sleeping-sickness. This article leaves nothing to be desired and is accompanied with some excellent plates. Dr. F. W. Mott's researches and discoveries of the part played by the central nervous system are duly chronicled. Relapsing fever is described by Dr. C. Schilling and the description is fully up to date. The ornithodorus moubata is shown in a very good illustration. Dr. L. Sander and Dr. Hennig write of the glossina morsitans and the stomoxys and of nagana, of surra and dourine, piroplasmosis, African coast fever, South African horse sickness, and rinderpest, amongst other subjects. Dr. Filippo Rho treats of psittacosis and the volume concludes with a well-written chapter on the less known tropical diseases by Dr. Mense.

We have read the concluding volume of this treatise with much instruction and pleasure. It is certainly the mos comprehensive work on tropical diseases yet published and should find a place in the library of every student of those diseases.

The Townsman's Farm. By "HOME COUNTIES." London, Paris, New York, Toronto, and Melbourne: Cassell and Co., Limited. 1908. Pp. 293. Price 6s. net.

THIS book is written by one who undoubtedly knows his subject well and who marshals his facts regarding farm life in its various aspects in an interesting and instructive manner. The first two chapters endeavour to show that the skill and ability of the farm labourer and the farmer are greatly underrated by the ordinary city dweller. "The Townsman's Farm" proves clearly that neither is Hodge a fool nor the farmer a blockhead. It is demonstrated that the good farm labourer is a remarkably able "handy man." As an apt illustration of the truth of this statement, the difficulties encountered in properly ploughing heavy land are pointed out, which it is asserted are as great as those of holding a boat's head to the wind in a sea. A comparison is made between a skilled farm labourer and a city bank clerk in favour of the former, not only so far as physique and staying powers are concerned but also as regards the value of his knowledge and experience. While we cannot but agree with most of the author's conclusions as to the efficiency of the farm labourer and the farmer and of the healthfulness of the lives led by both, it may be doubted whether the present-day labourer is quite so useful an all-round man on a farm as was his forefather. Again, in regard to the healthfulness of his life it is to be remembered that many of the cottages inhabited by farm labourers are overcrowded, ill-lighted, badly ventilated, and inadequately drained, oftentimes with a defective if not infected water-supply. The author is bold enough, as we have already pointed out, to hold up "Hodge" to comparison with the "typical bank clerk," to the "very possible advantage" of the former in "natural wit, acquired skill, and knowledge that a man sets store by at 60." We cannot follow him so far as this but are very ready to admit that to call a farm labourer an unskilled man is to proclaim a deep ignorance of the nature of his work.

The main object of the book, however, is to try to teach the townsman how to proceed when he desires to get "back to the land." The obstacles in his path are by no means minimised. He is told that he must first shed himself of his conceit and approach his task in a humble spirit. All the avenues which lead to farming are dealt with concisely but to the point. The agricultural colleges are discussed at some length, and the "fors" and "againsts" of this mode of learning the farming business are well set forth. The question of small holdings, a burning question of the day, is adequately reviewed. To emigration and colonial farming are devoted several pages, all of which appear to contain sound common sense and wise advice. Indeed, every phase of farming comes under brief notice.

A welcome note of optimism pervades the book throughout. The position of the British farmer is not painted in the black colours which are so usually employed, and it is refreshing and healthy in itself to have the opinion of an authority that there is a fair chance of success for the overworked and debilitated townsman not only in our colonies but even in Great Britain if the matter be grappled with determination and energy. At any rate, the gain to the individual from leading a strenuous life of hard work on the soil is too obvious to need emphasis and the townsman who is anxious so to do will find in these pages admirable advice for his guidance.

Atlas and Text-book of Human Anatomy. Vol. III. By Dr. JOHANNES SOBOTTA, Professor of Anatomy in the University of Würzburg. Edited, with additions, by J. PLAYFAIR MCMURRICH, A.M., Ph.D., Professor of Anatomy in the University of Toronto; formerly Professor of Anatomy in the University of Michigan. London and Philadelphia: W. B. Saunders Company. 1907. Quarto, pp. 342. Price 25*s.* net.

THE third and last volume of this Atlas is devoted to the remainder of the vascular system, the entire nervous system, and the organs of special sense, with the exception of the tongue and larynx, which were fully described in Vol. II. The mode of reproduction of the dissections is identical with that employed in the preceding volumes—viz., multicoloured lithography, autotype, and the three-colour process, while in conformity with the author's aims the text has been judiciously curtailed in order to produce a useful book for the student and the physician, rather than an atlas for the finished anatomist. The illustrations, all of which are faithful reproductions of actual dissections, are beautifully executed and show at a glance the relations of arteries, veins, and nerves, both to each other and to adjacent structures. The portion of the book devoted to the vascular system is divided into two sections dealing first with the arteries and secondly with the veins. This arrangement applies to the text rather than to the illustrations, for, whenever possible, the picture is a composite one of arteries, veins, and nerves. This commendable plan should be much appreciated by the student who requires a complete picture of a dissection rather than a view of a solitary vessel or nerve in a framework of muscle or bone. Where there are so many beautiful plates it is extremely difficult to single out any particular ones for distinction but we certainly think that those depicting the vessels of the head and neck and the pelvis are deserving of the highest praise.

The nervous system is treated in a very thorough manner. Commencing with the spinal cord and the brain, the author passes on to the cranial nerves, the spinal nerves and plexuses, and concludes with a description of the sympathetic system. Again in this section the text is more than amplified by a splendid series of drawings depicting sections and surface views of the brain and dissections of the nerves and plexuses, all of which give the reader a very clear idea of these important structures. The concluding chapters devoted to the eye and the ear contain a complete and accurate description of these organs and, as might be expected, are copiously illustrated.

We have nothing but praise for the work which, as an atlas, surpasses anything of its kind which we have yet seen and we wish it the success which it undoubtedly deserves.

JOURNALS AND MAGAZINES.

The Quarterly Journal of Medicine. Vol. I. No. 1 (October, 1907), No. 2 (January, 1908), and No. 3 (April, 1908). Oxford: At the Clarendon Press. Subscription 25*s.* per annum. Single numbers 8*s.* 6*d.* net.—This new medical contemporary is edited by six eminent physicians—Professor William Osler, Dr. J. Rose Bradford, Dr. A. E. Garrod, Dr. R. Hutchison, Dr. H. D. Rolleston, and Dr. W. Hale White. They will have the assistance of several colleagues, amongst whom may be mentioned Sir R. Douglas Powell, Professor T. Clifford Allbutt, Dr. J. K. Fowler, Dr. Byrom Bramwell, and Dr. Norman Moore. The journal will be conducted on the lines of the *Journal of Hygiene* or the *Zeitschrift für Klinische Medicin* and will be devoted to the publication of original papers dealing with clinical medicine. It will also include critical reviews on special subjects and diseases, but with this exception the journal will be entirely concerned with original communications. The publication will form the official organ of the Association of Physicians of Great Britain and Ireland, bearing the same relation to that body as the *Journal of Physiology* bears to the Physiological Society. Having these objects the new journal is likely to advance the interests of British medicine throughout the world and will, it is hoped, tend to make advances in medicine made by British physicians more extensively known amongst foreign nations than at present appears to be the case. The first number contains several communications of considerable interest. Dr. James Mackenzie contributes an article on Abnormal Inception of the Cardiac Rhythm. He considers a class of cases in which a very prominent and easily recognised symptom is a continuous irregularity of the heart's action. Clinically, these cases are found under two conditions: first, in the later stages of mitral disease, especially of mitral stenosis; and secondly, in those cases of irregular heart action so common in advancing years and usually associated with arterio-sclerosis. He further considers that a consideration of these cases is of the highest importance in affording a key to the pathology of the irregular heart. He contends that in such instances the normal sequence of the heart's contraction no longer prevails, that the ventricles alone may contract, or that the auricles and the ventricles contract simultaneously. As a deduction from the facts proving this proposition he suggests that the stimulus for contraction arises no longer from the usual place at the mouths of the great veins but at the *a-v* node described by Aschoff and Tawara situated at the auriculo-ventricular junction. Amongst other papers in this number dealing with the circulatory system are a Note on a Ready Method of Measuring the Venous Pressure without a Manometer, by Dr. George Oliver; and a Clinical Sphygmomanometer yielding Absolute Records of the Arterial Pressure, by Dr. A. G. Gibson.——No. 2 contains a careful paper upon the Pathology of the Cerebro-spinal Fluid derived from Lumbar Puncture, by Dr. J. Graham Forbes, based on 140 cases examined at the Great Ormond-street Hospital for Sick Children during the last three years. Dr. C. Rolleston contributes a Study of Certain Reflexes in Scarlet Fever, which contains some interesting clinical observations, especially that which records the temporary replacement of the flexor by the extensor plantar reflex in severe cases of the disease. Dr. James Mackenzie writes on the Extra-Systole: a Contribution to the Functional Pathology of the Primitive Cardiac Tissue, in a careful and learned paper in which he adduces evidence in favour of attributing the origin of extra-systoles to affection of the remains of the primitive cardiac tube. Dr. David Forsyth contributes an admirable first part to an essay upon the Parathyroids, dealing in this paper with their function and relation to the thyroid gland, of which we gave an account in THE LANCET of Feb. 29th, 1908, p. 659. Dr. Alexander G. Gibson contributes a study upon the Action of Digitalis on a case of Morbus Cordis, with many illustrative cardiograms, in which he observed the effect of the drug on four of the primary functions of cardiac muscle, and he also writes on the Heart in a case of Stokes-Adams Disease. Dr. Lewis Jones writes upon the interesting question of Cervical Ribs and their Relation to Atrophy of the Intrinsic Muscles of the Hand; and Dr. J. H. Drysdale and Dr. W. P. Herringham upon an Undescribed Form of Dwarfism with Spatulate Hands, a paper illustrated by reproductions of striking photographs. A beautiful colour plate illustrates a case of Ochronosis, reported by Mr. Edgar Reid, the clinical features being described by Professor William Osler and the urine by Dr. A. E. Garrod. The number is concluded by a Critical Review of Recent Work on Mediterranean Fever by Dr. J. W. H. Eyre who is admirably qualified to undertake such a contribution.——The first article in No. 3 is by Dr. F. J. Poynton who has done much to advance our knowledge of the subject of rheumatism. The present contribution deals first with the question of the frequency of acute rheumatism in children under five years of age. Some have maintained that acute rheumatism is very rarely if ever seen under the age of five years. Dr. Poynton has collected 52 cases in children under five and his paper is based on a study of these cases. The mortality was high. Eight cases died and five more were in a hopeless condition. 22 made partial recoveries with permanently damaged hearts. In seven out of the eight fatal cases a terminal pericarditis was present but the disease was unmistakeably rheumatism. In order to show the differences between these cases of rheumatic pericarditis and suppurative pericarditis from other causes, Dr. Poynton has collected and analysed 100 cases of suppurative pericarditis in childhood, the great majority of which were pneumococcal in origin. Eight were probably not pneumococcal in origin and were associated with acute osteo-myelitis and suppurating wounds, and in these there were multiple pyæmic abscesses. In the pneumococcic cases endocarditis was almost always absent, for only 1 per cent. showed any valvular lesions. In only one of the pneumonic cases was pericarditis the outstanding lesion; three cases showed signs of old pulmonary disease; 54 were associated with empyema and 31 with acute pleurisy or pneumonia; two with acute pulmonary tuberculosis, and eight with septic broncho-pneumonia. In 150 cases of fatal rheumatism in patients under the age of 12 years, which Dr. Poynton analysed ten years ago, 149 showed a valvular lesion. From a study of these cases he holds that rheumatism, though unusual, is by no means rare under the age of five years and that the facts connected with the disease in children strongly support the specific nature of the infection. The 52 cases are detailed. Mr. C. H. Treadgold has contributed a paper on Chloroma and Acute Lymphatic Leukæmia. The account begins with a description of four cases. In the first case a man died six days after the removal of a tooth, followed by persistent oozing of blood, and he had numerous purpuric patches. At the necropsy all the organs examined showed multiple small hæmorhages and there was marked degeneration of the small blood-vessels and their walls were infiltrated by the white cells of the blood. Mr. Treadgold points out the resemblances between chloroma and acute lymphatic leukæmia; he shows that the incidence of the disease is alike as regards age and sex and the symptomatology is very similar; in each there are present weakness, marked anæmia, a tendency to hæmorrhages, and metastases in the liver and kidneys and frequently in the lungs. The differences between the two diseases are chiefly these: in chloroma infiltration of the walls of the small blood-vessels is more marked, metastases are more frequent, the eroding power of the cells is greater, and the cells are on the whole larger and possess more protoplasm alike in the blood, the marrow, and the tissues. The primary growth in chloroma is often in the cranial bones and sometimes in the vertebræ. The initial growth appears not indefinitely in any part of the marrow but in the red marrow only. The question then arises, Does acute lymphatic leukæmia also originate in the marrow? and the answer is given that it does, and the reasons for this answer are: (1) that the marrow is always affected; (2) the cells in the infiltrations closely resemble the cells in the marrow and the blood; (3) the glands and spleen are seldom much enlarged and the more acute the condition the less the enlargement; and (4) the presence of a rapidly progressive anæmia due to deficient hæmatopoiesis. Mr. Treadgold suggests that acute lymphatic leukæmia has a special tendency to arise in the long bones. He discusses the causation of the green colour in chloroma; he rejects the theories that it is due to some pigment allied to bile pigment and that it is due to putrefaction. He is inclined to think that a degeneration of the abnormal myelocytes which exist in chloroma, aided by the broken-down products of hæmoglobin, is the real source of the colour. Mr. Treadgold sums up his opinions on acute lymphatic leukæmia and chloroma as follows: Acute lymphatic leukæmia is a tumour of malignant nature arising in the marrow of bones; the growth usually consists of amphoblasts, but leucoblastic and mixed types may occur. Chloroma is chiefly a tumour of myeloblasts and arises in the red marrow of bones. Dr. Forsyth continues his article on the Parathyroid Glands and in this number he deals with their pathology.[1] Mr. W. B. Hope and Dr. Herbert French have contributed a valuable paper on Persistent Hereditary Œdema of the Legs with Acute Exacerbations, or Milroy's Disease. They describe in detail the members of a family in which for five generations a certain number of the members (13 out of 42 individuals) have been liable to a persistent œdema of the legs. The cases described in this paper differ from the cases previously described by Milroy and others in that recurrent acute attacks also occurred. The authors consider that the condition is primarily a vaso-motor neurosis. The only treatment of any value is firm and constant bandaging of the legs, and if this bandaging is well carried out the affection does not seem to interfere with the occupation or life. The acute attacks, though dangerous in appearance, pass away spontaneously in a few days and in no case have they caused death. The paper is of the greatest interest, as very few instances of this disease have been recorded. Dr. A. M. Gossage's paper on the Inheritance of Certain Human Abnormalities is based on a number of investigations into hereditary diseases to see how far their occurrence is explicable by Mendel's law. Some of the conditions dealt with are keratosis palmaris et plantaris, epidermolysis bullosa, and hypotrichosis congenita. It seems to us a mistake to include such conditions as Mibelli's disease which some dermatologists look upon as microbic. The diagrams greatly facilitate the understanding of an intricate subject. Dr. A. E. Boycott has written a paper on Caisson Disease. This is due, as Bert showed, to bubbles of air being given off within the body during decompression. Saturation of the have already pointed out, to hold up "Hodge" to comparison with the "typical bank clerk," to the "very possible advantage" of the former in "natural wit, acquired skill, and knowledge that a man sets store by at 60." We cannot follow him so far as this but are very ready to admit that to call a farm labourer an unskilled man is to proclaim a deep ignorance of the nature of his work.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TUESDAY, MAY 26TH.

THE President's address and part of the work transacted by the Council on this, the first, day of its eighty-seventh session were published in our last issue (p. 1592).

The Recognition of Quebec Degrees.

A report was received from the Executive Committee to the effect that Part II. of the Medical Act (1886) having been extended by an Order in Council to the province of Quebec it has considered the conditions under which certain medical qualifications granted in the province shall be recognised for registration in the Colonial List of the Medical Register of the United Kingdom, and on May 25th, 1908, it adopted the following resolution:—

> That any person who holds (1) the degrees of Doctor of Medicine and Master of Surgery of McGill University, Montreal, together with the Licence to practise in the *Province of Quebec; or* (2) the degree of Doctor of Medicine of Laval University, Quebec, together with the aforesaid Licence to practise, shall be entitled to be registered in the Colonial List of the Medical Register, provided he satisfies the Registrar of the General Medical Council regarding the other particulars set forth in Part II. of the Medical Act, 1886.

The PRESIDENT moved that the report of the Executive Committee on the Quebec degrees should be received, that the Registrar should be directed to give effect to the resolutions therein, and that the Council should express its satisfaction with the step which had been taken, and its desire that similar resolutions might soon be established for the other provinces of Canada. He added that perhaps the expression of the Council's goodwill would accelerate that progress.

Sir JOHN MOORE seconded the motion and it was agreed to.

The Apothecaries' Hall of Ireland.

The PRESIDENT moved that the report of the Executive Committee in regard to the duties of assistant examiners to the Apothecaries' Hall of Ireland should be received. That report stated that the committee submitted for the approval of the Council the following recommendations:—

> *First*, that the examiners appointed by the Council to assist at the qualifying examinations held by the Apothecaries' Hall, Dublin, be instructed to conduct the surgical portion of these examinations, and, in addition, to supervise the medical and obstetrical portions, with the object of securing that at each qualifying examination the required standard of proficiency is maintained. *Secondly*, that the examiners be instructed to report fully for the information of the Council as to the methods and standards actually adopted at each qualifying examination, and as to the steps they have taken in fulfilment of the duties imposed upon them by Section 5 of the Medical Act, 1886.

The PRESIDENT said that it was made clear to them that the reports were of a confidential character communicated to the Council and not coming under the standing orders relating to inspection and visitation.

Dr. SAUNDBY seconded the motion.

Dr. ADYE CURRAN said that with reference to the point of law he should be glad to have a definite ruling from the Council's legal assessor as to whether or not it was lawful and in accordance with the statute made and provided for those gentlemen who were appointed to act as assistant examiners by the Council, under Paragraph 2, Section V., of the Medical Act of 1886, to have reported as "inspectors" and for such reports to have been forwarded to the Privy Council. Indeed, it was quite evident from the fact of the words "acting also as your inspectors" having been omitted from the last reports submitted by the assistant examiners that the Council admitted the illegality of the action. This was a matter of very grave importance, affecting not only the reputation of the Council for justice and fair play but also the very existence of the body which he represented. For a number of years past the Council had lost no opportunity of penalising the Hall by every means in its power, and by imposing perpetual inspections and reports had materially injured it both in reputation and, what was of more importance, financially. He would therefore most respectfully ask the Council what reparation it was disposed to make in the future for the injury inflicted by its action in the past. The Executive Committee, apparently not yet satisfied, recommended that even still more elaborate reports should be furnished in the future by the Apothecaries' Hall of Ireland, but it was careful not to recommend that a like duty should be performed by the assistant examiners appointed under precisely similar terms to the Society of Apothecaries of London. Why was the exemption for London and not for Dublin? His board felt very keenly the action taken by the Council, for which there did not seem to have been any just cause. On their behalf he would ask the Council to discontinue, at least for the present, all reports and by resolution to cause those already illegally made to be rescinded, notifying the Privy Council accordingly. Failing that, his board might be obliged to seek a remedy elsewhere. He moved that the reports should be discontinued.

The PRESIDENT said that Dr. Adye-Curran had been under a misunderstanding in one of his remarks. The Council was not acting illegally in this matter.

Mr. HENRY MORRIS moved that the discussion should be postponed until the counsel to the Council was present.

Dr. LINDSAY STEVEN seconded this and it having been agreed to the discussion was adjourned.

WEDNESDAY, MAY 27TH.

The Council resumed its sittings at its offices in Oxford-street, to-day. Dr. DONALD MACALISTER, the President, was in the chair.

The Re-election of the President.

The official notification was made of the appointment of Dr. Donald MacAlister, the President, as Representative on the Council of the University of Glasgow.

The PRESIDENT thereupon said that in accordance with statute he had handed in his resignation as member for the University of Cambridge and by doing so he vacated the chair.

Mr. Tomes, as senior treasurer, took the chair.

Dr. MacAlister was then formally introduced to the Council as the Representative of the University of Glasgow. He was greeted with loud applause.

Dr. LITTLE said: I have much pleasure in moving that Dr. Donald MacAlister be elected President of the General Medical Council. I do not think it has ever occurred that the Council has had an opportunity of electing to this office a man of whose powers as President it was already aware. We have all admired the way in which the business of the Council has been conducted by Dr. MacAlister. His many-sided qualities have been most valuable to us. His uniform courtesy has pleased us all. His power of negotiating with Government departments is well known. His financial ability has asserted itself in retrieving our shattered finances. We have every reason to be pleased with the way in which he has discharged his duties. I am sure I only give an echo to the feelings of members when I propose that Dr. MacAlister be elected President.

Dr. McVAIL: As one of the electors of the University of Glasgow, which now returns Dr. MacAlister to this Council, I have very great pleasure in seconding the motion. I am sure we in Glasgow may well be proud in having the representative of our University as President of this Council. We know by the good work which he has done at Cambridge and Glasgow that the Council will prosper under his guidance.

The motion was carried by acclamation.

Mr. TOMES said: Dr. MacAlister, I have great pleasure to announce to you that you have been unanimously re-elected to the position of President of the General Medical Council. I congratulate you.

Dr. MACALISTER then resumed the chair. He said: I have most cordially to express my thanks for the too flattering words that have been spoken by Dr. Little and Dr. McVail and for the cordiality with which you have received them. It was a matter of profound gratitude to me when you entrusted me with the presidency of the Council three and a half years ago. I am doubly grateful and doubly proud that you have renewed that confidence to-day. I will endeavour to retain the confidence you have reposed in me. I thank you most heartily for the brotherly, friendly spirit with which I have always been received and supported in this Council.

The Council's Jubilee.

The PRESIDENT then moved that—

> The President, treasurers, and chairman of the Business Committee be appointed a committee to make arrangements for the celebration of the Council's jubilee in November, 1908.

He hoped that it would be possible to have some reunion on Nov. 23rd.

The motion was agreed to.

tissues takes place slowly: probably about five hours are required; therefore short exposures are much less dangerous than longer ones. Slow decompression is essential to avoid caisson disease but Dr. Boycott tells us that the absolute air pressure may always be reduced to half the absolute pressure at which the tissues are saturated without the risk of causing symptoms, but the slowness of the decompression increases as the pressure falls. Uniform decompression is too slow at first and too rapid later. Young men only should be employed and fat men should certainly be excluded. The only specific treatment of caisson disease is recompression which should be undertaken immediately symptoms appear.

The Quarterly Journal of Microscopical Science. Edited by Sir RAY LANKESTER, K.C.B., F.R.S., with the coöperation of ADAM SEDGWICK, M.A., F.R.S., SYDNEY J. HICKSON, M.A., F.R.S., and E. A. MINCHIN, M.A. With lithographic plates and text figures. New series. No. 203 (Vol. LI., Part 3). London: J. and A. Churchill. Price 10*s.* net.—The articles contained in this number are: 1. The Chætognathi or Primitive Mollusca, with a bibliography, by R. T. Günther, F.L.S., Fellow of Magdalen College, Oxford. The chætognathi are commonly named arrow worms and resemble in form the Whitehead torpedo and Mr. Günther's object is to show that the molluscan resemblances are shared by all the chief organs in the chætognath anatomy, as by the nervous, alimentary, genital, and other systems. He does not propose to merge them in any one of the existing molluscan classes but regards them as modern and modified representatives of a free-swimming ancestor from which the molluscan phylum has sprung. Mr. Günther considers the several organs in topographical order. 2. The Structure, Development, and Bionomics of the House Fly, Musca Domestica (Linn.). Part 1. The Anatomy of the Fly, by C. Gordon Hewitt, M.Sc., lecturer in economic zoology, University of Manchester. This article contains a full description of the anatomy of the house fly and is illustrated by many well-drawn plates. 3. Trichomastix Serpentis (new species), by C. Clifford Dobell, B.A., scholar of Trinity College, Cambridge, with a plate. Mr. Dobell states that the subject of the paper is a parasitic flagellate that he obtained from the rectum of a boa constrictor (Linn.). 4. Notes on Common Species of Trochus, by H. J. Fleure and Muriel M. Gettings, University College, Aberystwyth, with a plate. 5. Note on the Formation of the Skeleton in the Madreporaria, by Maria M. Ogilvie Gordon, F.L.S., D.Sc. Lond., Ph.D. Munich. 6. Studies in Spicule Formation. 7. The Scleroblastic Development of the Plate and Anchor Spicules of Synapta and of the Wheel Spicules of the Auricularian Larva, by W. Woodland, the zoological laboratory, King's College, London, with two plates and six text figures. Part 1. The Spicules of Synapta Inhærens and Synapta Digitata.

The Journal of Physiology. Edited by J. N. LANGLEY, F.R.S. Vol. XXXVII., No. 1, May 6th, 1908. London: C. F. Clay. Price 5*s.*—The articles contained in this number of the journal are: 1. Axon Bifurcation in Regenerated Nerves, by W. A. Osborne and Basil Kilvington, from the physiological laboratory, University of Melbourne. The experiments of these observers show that motor axon bifurcation can take place if a plurality of path is offered to a regenerating axon at some distance from its central point of regeneration; if a sensory and motor path be offered to the regenerating motor nerve one branch of the dichotomised axon passes to the muscle originally supplied by the undivided axon and the other branch travels down the sensory path. In the dog afferent nerve fibres cannot degenerate along motor paths. 2. Differential Method of Blood Gas Analysis, by Joseph Barcroft. 3. A note on the Total Fat of Rats, Guinea-pigs, and Mice, by A. E. Boycott and G. C. C. Damant, from the Gordon laboratory, Guy's Hospital. This article gives the relations in tame rats between size and fatness and between sex and fatness, and the weights of fats as estimated by Leathes' modification of Liebermann's method in guinea-pigs, dormice, and tame mice. 4. Crystalline Egg Albumin, by Edith G. Willcock, Fellow of Newnham College, Cambridge. Miss Willcock having occasion to prepare crystalline albumin in order to estimate the phosphorus that it contains found that following Hopkin's method the rotatory effect usually obtained by her was about 31. 5. On the Munchi Arrow Poison and Strophanthin, by George Ralph Mines, B.A., scholar of Sidney Sussex College, Cambridge. The poisonous properties of the Munchi arrow poison seem to be due to strophanthin glycoside. 6. Colchicine with special reference to its mode of action and effect on Bone Marrow, by W. E. Dixon, M.A., M.D., and Walter Madden, M.A., M.D. This number also contains the proceedings of the Physiological Society for Jan. 25th and for March 21st, 1908.

Verhandlungen des Vereins Süddeutscher Laryngologen, 1907 (Proceedings of the South German Laryngological Society). Würzburg: A. Stuber. 1907. Price 4 marks.—This volume of the South German Laryngological Society contains 17 papers:—1. A Case of Ichthyosiform Affection of the whole Surface of the Body and of the Upper Air Passages, by Siebermann. 2. A Contribution to the Knowledge of Toxic Laryngeal Paralyses, by Seifert. 3. (*a*) Laryngotomy without Cannula or Chloroform in Scopolamin-morphia Anæsthesia; and (*b*) Laryngoceles in Human Beings, by Avellis. 4. The Value of Transillumination in Disease of the Frontal Sinus, by Vohsen. 5. Microscopical Condition of the Mucous Membrane in Chronic Empyema of the Accessory Sinuses, by Oppikofer. 6. Further Experience in the Radical Operation for Chronic Empyema of the Sphenoidal Sinus, by Denker. 7. Demonstration of Universal Electro-medical Apparatus for Consulting-room and Operation-room, by Katz. 8. Œsophagoscopic Diagnosis of Disease of the Upper Section of the Alimentary Canal, by Starck. 9. (*a*) Further Report on Hypopharyngoscopy; and (*b*) Bronchoscopy, by von Eicksen. 10. Technique of Bronchoscopy, by Brünings. 11. Bronchoscopy, by Nager. 12. Meningitis following Acute Empyema of the Sphenoidal Sinus, Recovery, by Kander. 13. Local Serous Meningitis in Acute Sphenoidal Sinusitis, Spontaneous Recovery, by Avellis. 14. A case of Acute Leukæmia with Death after Adenotomy, by Hug. 15. (*a*) On Laryngological Dangers; and (*b*) On Theories of Asthma. All these excellent papers will amply repay careful perusal.

Le Laryngoscope. April, 1908. Paris: Maloine. Pp. 52. Price 2 francs.—This number contains a very interesting paper on Prolonged Dysphagia as a Relative Sign of Syphilis of the Œsophagus, by Dr. J. Garel; and a valuable paper by Dr. de Lalande on Gastroscopy. The latter is very fully illustrated and includes a coloured plate showing 24 views of conditions found in the stomach. There is also a short report of a case of Fibro-sarcoma of the Soft Palate by Dr. Molini. Besides this there is a short leading article on the treatment of epistaxis.

Geschichte der Laryngologie in Würzburg (History of Laryngology in Würzburg). Von Professor Dr. OTTO SEIFERT. Würzburg: Curt Kabitzsch. 1908. Pp. 63. Price 3½ marks.—In this book is set forth with careful accuracy and detail so thoroughly Teutonic the history of the twin specialties of rhinology and laryngology in Würzburg. This historical essay was compiled by Professor Seifert in honour of, and dedicated to, Professor B. Fränkel on his seventieth birthday. The records of the laryngological clinic and clinical instruction in this University go back to 1859, Dr. Gerhardt having been the first teacher.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TUESDAY, MAY 25TH.

THE President's address and part of the work transacted by the Council on this, the first, day of its eighty-seventh session were published in our last issue (p. 1592).

The Recognition of Quebec Degrees.

A report was received from the Executive Committee to the effect that Part II. of the Medical Act (1886) having been extended by an Order in Council to the province of Quebec it has considered the conditions under which certain medical qualifications granted in the province shall be recognised for registration in the Colonial List of the Medical Register of the United Kingdom, and on May 25th, 1908, it adopted the following resolution:—

That any person who holds (1) the degrees of Doctor of Medicine and Master of Surgery of McGill University, Montreal, together with the Licence to practise in the Province of Quebec; or (2) the degree of Doctor of Medicine of Laval University, Quebec, together with the aforesaid Licence to practise, shall be entitled to be registered in the Colonial List of the Medical Register, provided he satisfies the Registrar of the General Medical Council regarding the other particulars set forth in Part II. of the Medical Act, 1886.

The PRESIDENT moved that the report of the Executive Committee on the Quebec degrees should be received, that the Registrar should be directed to give effect to the resolutions therein, and that the Council should express its satisfaction with the step which had been taken, and its desire that similar resolutions might soon be established for the other provinces of Canada. He added that perhaps the expression of the Council's goodwill would accelerate that progress.

Sir JOHN MOORE seconded the motion and it was agreed to.

The Apothecaries' Hall of Ireland.

The PRESIDENT moved that the report of the Executive Committee in regard to the duties of assistant examiners to the Apothecaries' Hall of Ireland should be received. That report stated that the committee submitted for the approval of the Council the following recommendations:—

First, that the examiners appointed by the Council to assist at the qualifying examinations held by the Apothecaries' Hall, Dublin, be instructed to conduct the surgical portion of these examinations, and, in addition, to supervise the medical and obstetrical portions, with the object of securing that at each qualifying examination the required standard of proficiency is maintained. Secondly, that the examiners be instructed to report fully for the information of the Council as to the methods and standards actually adopted at each qualifying examination, and as to the steps they have taken in fulfilment of the duties imposed upon them by Section 5 of the Medical Act, 1886.

The PRESIDENT said that it was made clear to them that the reports were of a confidential character communicated to the Council and not coming under the standing orders relating to inspection and visitation.

Dr. SAUNDBY seconded the motion.

Dr. ADYE CURRAN said that with reference to the point of law he should be glad to have a definite ruling from the Council's legal assessor as to whether or not it was lawful and in accordance with the statute made and provided for those gentlemen who were appointed to act as assistant examiners by the Council, under Paragraph 2, Section V., of the Medical Act of 1886, to have reported as "inspectors" and for such reports to have been forwarded to the Privy Council. Indeed, it was quite evident from the fact of the words "acting also as your inspectors" having been omitted from the last reports submitted by the assistant examiners that the Council admitted the illegality of the action. This was a matter of very grave importance, affecting not only the reputation of the Council for justice and fair play but also the very existence of the body which he represented. For a number of years past the Council had lost no opportunity of penalising the Hall by every means in its power, and by imposing perpetual inspections and reports had materially injured it both in reputation and, what was of more importance, financially. He would therefore most respectfully ask the Council what reparation it was disposed to make in the future for the injury inflicted by its action in the past. The Executive Committee, apparently not yet satisfied, recommended that even still more elaborate reports should be furnished in the future by the Apothecaries' Hall of Ireland, but it was careful not to recommend that a like duty should be performed by the assistant examiners appointed under precisely similar terms to the Society of Apothecaries of London. Why was the exemption for London and not for Dublin? His board felt very keenly the action taken by the Council, for which there did not seem to have been any just cause. On their behalf he would ask the Council to discontinue, at least for the present, all reports and by resolution to cause those already illegally made to be rescinded, notifying the Privy Council accordingly. Failing that, his board might be obliged to seek a remedy elsewhere. He moved that the reports should be discontinued.

The PRESIDENT said that Dr. Adye-Curran had been under a misunderstanding in one of his remarks. The Council was not acting illegally in this matter.

Mr. HENRY MORRIS moved that the discussion should be postponed until the counsel to the Council was present.

Dr. LINDSAY STEVEN seconded this and it having been agreed to the discussion was adjourned.

WEDNESDAY, MAY 27TH.

The Council resumed its sittings at its offices in Oxford-street, to-day. Dr. DONALD MACALISTER, the President, was in the chair.

The Re-election of the President.

The official notification was made of the appointment of Dr. Donald MacAlister, the *President*, as Representative on the Council of the University of Glasgow.

The PRESIDENT thereupon said that in accordance with statute he had handed in his resignation as member for the University of Cambridge and by doing so he vacated the chair.

Mr. Tomes, as senior treasurer, took the chair.

Dr. MacAlister was then formally introduced to the Council as the Representative of the University of Glasgow. He was greeted with loud applause.

Dr. LITTLE said: I have much pleasure in moving that Dr. Donald MacAlister be elected President of the General Medical Council. I do not think it has ever occurred that the Council has had an opportunity of electing to this office a man of whose powers as President it was already aware. We have all admired the way in which the business of the Council has been conducted by Dr. MacAlister. His many-sided qualities have been most valuable to us. His uniform courtesy has pleased us all. His power of negotiating with Government departments is well known. *His financial* ability has asserted itself in retrieving our shattered finances. We have every reason to be pleased with the way in which he has discharged his duties. I am sure I only give an echo to the feelings of members when I propose that Dr. MacAlister be elected President.

Dr. MCVAIL: As one of the electors of the University of Glasgow, which now returns Dr. MacAlister to this Council, I have very great pleasure in seconding the motion. I am sure we in Glasgow may well be proud in having the representative of our University as President of this Council. We know by the good work which he has done at Cambridge and Glasgow that the Council will prosper under his guidance.

The motion was carried by acclamation.

Mr. TOMES said: Dr. MacAlister, I have great pleasure to announce to you that you have been unanimously re-elected to the position of *President* of the General Medical Council. I congratulate you.

Dr. MACALISTER then resumed the chair. He said: I have most cordially to express my thanks for the too flattering words that have been spoken by Dr. Little and Dr. McVail and for the cordiality with which you have received them. It was a matter of profound gratitude to me when you entrusted me with the presidency of the Council three and a half years ago. I am doubly grateful and doubly proud that you have renewed that confidence to-day. I will endeavour to retain the confidence you have reposed in me. I thank you most heartily for the brotherly, friendly spirit with which I have always been received and supported in this Council.

The Council's Jubilee.

The PRESIDENT then moved that—

The President, treasurers, and chairman of the Business Committee be appointed a committee to make arrangements for the celebration of the Council's jubilee in November, 1908.

He hoped that it would be possible to have some reunion on Nov. 23rd.

The motion was agreed to.

Penal Cases.

The Council then took up the consideration of penal cases.

The first was the consideration (adjourned from Nov. 27th, 1907) of the case of Duncan Shaw Morrison, registered as of Invergowrie, Perthshire, M.B., Mast. Surg. 1891, Univ. Edin., who had been summoned to appear before the Council to answer the following charges:—

That you were on the 24th day of September, 1906, convicted of the following crime or offence at Lochgilphead police court, namely, of breach of the peace, and on the 11th day of February, 1907, at the same court, of the same crime or offence, and on the 18th day of September, 1907, at the same court, of the following crime or offence, namely, of a contravention of Section 70 of the Licensing (Scotland) Act, 1903.

At the conclusion of the November proceedings the President announced that the Council had adjourned the consideration of the three convictions proved against Dr. Morrison until the May session, 1908, when he would be required to be present.

When the case was called Dr. Morrison failed to appear and the Council immediately proceeded to deliberate on it *in camerâ*.

When the public had been readmitted the PRESIDENT said: I have to announce that the Registrar has been directed to erase from the Medical Register the name of Duncan Shaw Morrison.

The next case was another which was adjourned from November. It concerned William Henry Roberts, registered as of 63, Lower Mount-street, Dublin, Lic. R. Coll. Phys. Edin. 1885, Lic. R. Coll. Surg. Edin. 1885, who had been summoned to appear before the Council on the following charge:—

That you have knowingly assisted certain persons who are not registered as dentists—namely, Mr. Keogh, of No. 4, Lower Mount-street, Dublin, and Mr. John Blake Dillon, Messrs. William-Steyn, and Mr. M. William-Steyn, all of 23, Rathmines-road, Dublin, in performing operations in dental surgery by administering and offering to administer anæsthetics, and have so enabled these persons to treat patients and to engage in dental practice as if they were duly qualified in dentistry and dental surgery; and that in relation thereto you have been guilty of infamous conduct in a professional respect.

The complainants were the Irish branch of the British Dental Association. At the conclusion of the November proceedings the President said to Mr. Roberts: I have to inform you that the Council has found the facts alleged against you proved to its satisfaction, and that the further consideration of the facts proved has been adjourned till the session that will be held in May next on a day of which you will receive due notice, and when you will be expected to be present.

Mr. ROBERTS, who appeared in person, said that since his case was under consideration in last November he had strictly adhered to the undertaking given on his behalf. It was not his intention to offend in any way again.

After deliberation *in camerâ*, the PRESIDENT announced the decision of the Council as follows: Mr. Roberts, the Council having further considered the facts proved against you does not judge you guilty of infamous conduct in a professional respect. The case is closed.

Mr. ROBERTS: I wish to express my regret at having offended against the regulations of the Council.

The PRESIDENT: The Council will take note of your expression.

The Council passed on to the consideration (adjourned from Nov. 29th, 1907) of the case of Morgan Watkin Williams, registered as of Trewernen, Llantwitfardre, Pontypridd, South Wales, M.B., Bac. Surg. 1900, Univ. Glasg., who had been summoned to appear before the Council on the following charge:—

(1) That you, being a duly qualified and registered medical practitioner, while acting as assistant to Mr. John Bernard Gabe, also a duly qualified and registered medical practitioner, by your countenance, assistance, and coöperation knowingly enabled an unqualified and unregistered person—namely, Mr. Frank Hannah—who was also acting as assistant to the said J. B. Gabe, to attend and treat patients and engage in medical practice as if the said F. Hannah were duly qualified and registered; (2) that you signed a certificate of death—namely, of Alice Mary Jenkins—which stated that you had attended the said Alice Mary Jenkins in her last illness, and that you last saw her alive on May 4th, 1907, whereas in fact you had not so attended her or seen her, but the said Frank Hannah had alone attended and seen her; and that in relation thereto you have been guilty of infamous conduct in a professional respect.

At the conclusion of the proceedings in November the President, addressing Mr. Williams, said: In your case the Council has come to the decision that the facts alleged against you have been proved to its satisfaction, but has adjourned the further consideration of the facts proved until the May session, when you will be required to be present and to furnish evidence of your conduct in the interval, especially in relation to the giving of certificates and association with unqualified assistants.

Mr. WILLIAMS appeared in person. He said that he was sorry for what had occurred. He had had no intention of deriving any pecuniary benefit from it. He had not been associated with any unqualified assistants since and he had not signed any death certificates except in proper order. He need not say that this matter would never occur again.

After deliberation *in camerâ* the PRESIDENT announced the decision of the Council. He said: Mr. Williams, the Council have further considered the facts proved against you and they do not judge you guilty of infamous conduct in a professional respect.

The next case for consideration was that of James Brookes, registered as of 88, St. Paul's-road, Sparkbrook, Birmingham, but who had also a surgery at 105, Ladypool-road, Birmingham, Lic. R. Coll. Phys. Edin. 1871, Lic. Fac. Phys. Surg. Glasg. 1871, who had been summoned to appear before the Council on the following charge:—

That you have knowingly authorised or allowed an unqualified and unregistered person—namely, one J. W. Austin Brookes—to attend and prescribe for patients in your name and on your behalf and to sign in your name documents purporting to be medical certificates of the unfitness of children to attend school, without having yourself attended the children, and thereby have enabled the said J. W. Austin Brookes to act in relation to these cases as if he were a person duly qualified and registered. In particular the said J. W. Austin Brookes has attended and prescribed for the following persons—viz., Minnie Fisher, Elsie Preece, and Lilian Meadows; and the said J. W. Austin Brookes has signed such certificates in the following cases—namely, Minnie Fisher, Elsie Preece, and Lilian Meadows.

The matter was brought to the notice of the Council by the Education Committee of the city of Birmingham.

Mr. Brookes attended in person and was accompanied by Mr. John Pritchard, of Messrs. T. W. Walthall and Pritchard of Birmingham, his solicitors.

The Solicitor to the Council (Mr. WINTERBOTHAM) read various letters and statutory declarations in connexion with the case.

Evidence was submitted on behalf of the complainants. Mr. BROOKES gave evidence on his own behalf and Mr. J. W. A. BROOKES also appeared as a witness.

The Council at the conclusion of the hearing reserved its decision until the following day.

The Council then adjourned.

THURSDAY, MAY 28TH.

The Council resumed its sittings to-day, Dr. DONALD MACALISTER, the President, being in the chair.

Penal Cases.

The consideration of the decision in the case of James Brookes, registered as of 88, St. Paul's-road, Sparkbrook, Birmingham, adjourned from the previous day was then resumed.

After deliberation *in camerâ* the PRESIDENT announced the decision as follows: Mr. Brookes, I have to announce to you that the Council having carefully considered the facts proved against you have decided to direct the Registrar to erase your name from the Medical Register.

The Council then took up the consideration (adjourned from Nov. 27th, 1907) of the case of John P. Rafter, registered as of 338, Stanley-road, Bootle, Liverpool; Lic. Apoth. Hall, Dubl. 1882; Lic. K.Q. Coll. Phys. Irel. 1886; Lic., Lic. Midwif. 1892, R. Coll. Surg. Irel., who had been summoned to appear before the Council on the following charge:—

That you have systematically sought to attract patients in Great Crosby and Waterloo, Lancashire, by the distribution of cards from house to house and in the street; and that in relation thereto you have been guilty of infamous conduct in a professional respect.

The complainants were the Medical Defence Union, who were represented by Dr. Bateman.

At the conclusion of the proceedings in November the President, addressing Mr. Rafter, said: I have to announce to you that the Council have found the facts alleged against you in the notice of inquiry have been proved to their satisfaction and that they have adjourned the further consideration of your case to the May session of the Council, when you will be expected to be present and to produce evidence as to your conduct in the interval.

Mr. RAFTER submitted several certificates testifying to his character. These included letters from the professor of midwifery in the University of Liverpool, the medical officer of health of the Waterloo urban sanitary district, the coroner for South-West Lancashire, the Mayor of Bootle, and other gentlemen.

Dr. **BATEMAN** made a statement to the Council.

Mr. **RAFTER** said that he had carried out the instructions of the Council and had handed in evidence with respect to his conduct. He explained that he was in the height of the municipal elections when the incident complained of occurred. He never authorised the distribution of the cards in the way in which they had been distributed. He complained that the charge brought against him had caused him great financial loss. The cards complained of were not intended to be distributed broadcast. He was very sorry and the incident had given him no end of worry.

After the usual deliberation *in camerâ* the **PRESIDENT**, in announcing the decision, said: Mr. Rafter, I have to announce to you that the Council having further considered the facts proved against you does not judge you guilty of infamous conduct in a professional respect.

Mr. **RAFTER** expressed his gratitude to the Council for its decision.

Consideration was then given to a charge against Frederick Aubin Monks, registered as of Woodcliffe House, Burgess-hill, Hampstead, N.W., Lic. Soc. Apoth. Lond. 1871; Mem. R. Coll. Surg. Eng. 1871; Lic. R. Coll. Phys. Edin. 1873.

The complainants in this case were the Medical Defence Union. Mr. Monks was represented by Mr. C. F. Gill, K.C., who made a statement on his behalf to the effect that his conduct was not such as to bring it within the charge.

The **PRESIDENT**, after the Council had come to their finding *in camerâ*, said: Mr. Monks, I have to tell you that the Council have come to the following decision. The facts alleged against you have not been proved to the satisfaction of the Council. That closes the case.

The next case to come under consideration was that of Stanley Southam, registered as of 512, Rochdale-road, Manchester, Lic. Soc. Apoth. Lond. 1900, who had been summoned to appear before the Council on the following charge:—

> That you acted as "cover" to an unregistered dentist—namely, Mr. Sydney Smith of 163, Conran-street, Harpurhey, Manchester—by systematically acting for him in your own surgery, in respect of the treatment of patients sent to you by him for dental operations requiring an anæsthetic, and that in relation thereto you have been guilty of infamous conduct in a professional respect.

The complainants again in this case were the Medical Defence Union. Mr. Southam was accompanied by his solicitor, Mr. Hamilton, Manchester, who made a statement on his behalf.

Mr. **SOUTHAM** gave evidence with regard to his own position. He said that his cards, which Smith had got, were not given to him by witness, but in his absence they had been obtained from Mrs. Southam. He had not paid Smith a penny. There was absolutely no arrangement between him and Smith.

The **PRESIDENT** announced the decision of the Council as follows: Mr. Southam, I have to inform you that the Council having considered your case have come to the conclusion that the facts alleged against you in the notice of inquiry have not been proved to their satisfaction. That closes the case.

The Council proceeded to deal with a complaint against Mr. Arthur Ward which had been reported on by the dental committee. The registrar read the report which contained the following passage:—

> The Committee find that the following facts were established by the evidence: Arthur Ward was registered in the Dentists Register on Feb. 25th, 1883, as in practice before July 22nd, 1878, and his address in the Register for the current year is 61, Bull-street, Birmingham. The said Arthur Ward has issued and circulated a pamphlet containing statements of an objectionable character, viz., laudatory statements as to his own skill and methods, and depreciatory statements as to the work of other practitioners, and claims of superiority over other practitioners. After receiving notice of the charge in this case the said Arthur Ward withdrew the said pamphlet and issued another pamphlet which omits certain depreciatory statements as to the work of other practitioners, but contains laudatory statements as to his own skill and methods. The said Arthur Ward expressed his willingness to undertake to withdraw the pamphlet altogether and not to issue any similar advertisements in future.

The British Dental Association, the complainants, were represented by counsel, Mr. Hart. Mr. Ward was accompanied by his solicitor, Mr. W. Coley of Birmingham.

Mr. **HART** pointed out that the undertaking of Mr. Ward was "not to issue any similar advertisements in future." There was no undertaking that he would not indulge in any further advertising.

Mr. **COLEY** said that his client was perfectly willing to give an undertaking in the fullest terms desired. He was prepared to give up any pamphlet or advertisement at all with regard to his practice.

The **PRESIDENT** announced the decision of the Council in the following terms: Mr. Ward, I have to tell you that the Council have carefully considered the report of the Dental Committee and they have adjourned the further consideration of your case until the next session of the Council to be held in November, when you will be required to appear and to give evidence as to your conduct in the interval, and especially in regard to the performance of your undertaking not to issue advertisements of any description in future.

Mr. **WARD**: I would like to express my extreme regret at having transgressed against the resolution of the Council and I thank you for your consideration.

The next complaint was against William John Watson. The Dental Committee had given it their consideration and their report was read by the Registrar. It contained the following statement:—

> The committee find that the following facts were established by the evidence:—William John Watson was registered in the Dentists Register on Dec. 31st, 1878, as in practice before July 22nd, 1878, and his address in the Register for the current year is 8, New-street, Birmingham. In the year 1881 the qualification of Licentiate in Dental Surgery of the Royal College of Surgeons, Edinburgh, was added to his name in the Dentists Register. He was, however, deprived of that diploma by the College in the year 1891 for advertising contrary to the declaration signed by him on admission.
>
> In the year 1901 the said William John Watson caused to be printed, issued, and circulated a pamphlet containing statements of an objectionable character—viz., laudatory statements as to his own skill and methods, and depreciatory statements as to the work of other practitioners and claims of superiority over other practitioners. This pamphlet contains a statement that the said William John Watson had obtained the above-mentioned diploma by examination. Testimonials are also printed in the pamphlet which state that the said William John Watson possesses the said diploma. These testimonials are not dated, but they were in fact given before 1891 (when the said William John Watson was deprived of the said diploma) to assist him in obtaining an appointment he was then proposing to apply for. In the year 1903 or in the year 1905 (the evidence was not clear as to which date) the said William John Watson instructed his printer to destroy the remaining stock of these pamphlets, and the bulk of them were then destroyed, but one parcel was not destroyed, and some of these were recently distributed.
>
> The said William John Watson stated that these copies were accidentally discovered, and that they were distributed inadvertently, and that the remainder have since been destroyed. He undertook in future not to issue the same or any other similar pamphlet, and to discontinue all advertisements.

The complainants were the British Dental Association. Mr. Watson was represented by Mr. A. C. Hayes, his solicitor.

Mr. **HAYES** made a statement on behalf of his client. He explained that the Edinburgh diploma was taken away because he exhibited a show case with teeth. He hoped that the Council would accept the statement of Mr. Watson with regard to the advertisements.

The Council having deliberated *in camerâ*, the **PRESIDENT** announced its decision as follows: Mr. Watson, the Council have given careful consideration to the report of the Dental Committee and have come to the conclusion to defer further consideration of your case until the next session of the Council in November, when you will be required to be present and present satisfactory evidence as to your conduct in the interval, with particular reference to your undertaking to discontinue the use of all advertisements.

The Council then adjourned.

FRIDAY, MAY 29TH.

The Council resumed its sittings at its offices at 299, Oxford-street, W. Dr. **DONALD MACALISTER**, the President, was in the chair.

The Catford Case.

The Council resumed the consideration of a case adjourned from Nov. 29th, 1907, concerning John Papa Nicolas, registered as of 87, Dowanhill-road, Catford, S.E., M.R.C.S. Eng., L.R.C.P. Lond. 1904, who had been summoned to appear before the Council on the following charge:—

> That you have systematically canvassed in Catford for patients by personal visits to patients of Mr. Thomas William Atkinson and to others, both while you were in the employment of the said Thomas William Atkinson and subsequently, and that in the course of such canvass you disparaged the qualifications and skill of the said Thomas William Atkinson and extolled your own; and that in relation thereto you have been guilty of infamous conduct in a professional respect.

After the case had been under consideration for a day in November the Council postponed further hearing of it in accordance with an intervention of the King's Bench Division.

The complainants were the London and Counties Medical Protection Society. They were represented by counsel, Mr. Neilson, who was accompanied by Dr. Hugh Woods, the secretary to the society.

Mr. John Papa Nicolas attended and was accompanied by Mr. H. J. Randolph Hemming, his solicitor.

At the November proceedings the opening statement of the complainants was made and Mr. Thomas William Atkinson was examined and cross-examined.

Mr. HEMMING at the outset raised an objection to the competency of the Council to hold the inquiry. For 50 years its jurisdiction had been exercised. However, he contended that the jurisdiction was *ultra vires*. The object of the Medical Act was stated in the preamble to be to enable persons to distinguish between qualified and unqualified practitioners. The Council only registered the qualification. It was clear that the Act was not passed in order to give any new form of jurisdiction. The Council had to keep the Medical Register, to deal with the registration of dentists, and with the education of practitioners and the compilation of the Pharmacopœia. The language of the statute should not be construed so as to erect a new tribunal with powers far in excess of those exercised by magistrates. He therefore respectfully urged that the Council had no jurisdiction conferred upon it under Section 29 of the Medical Act, 1858, to try Mr. Nicolas for infamous conduct or to deprive him of his qualifications and status as a medical practitioner.

Mr. LUSHINGTON (the legal assessor): This Council entertains no doubt whatever in the matter in this case. We have received the objection and put it on the file.

Mr. HEMMING proceeded to raise another objection. He had to contend that the proceedings were irregular and void in consequence of a rule of the Council not having been carried out, and in consequence of the accused practitioner not having been heard in the preliminary inquiry as he ought to be heard.

Mr. LUSHINGTON: We cannot receive that objection any further.

Mr. HEMMING went on to submit that his client was entitled to put his objection before his judges, and although it might not satisfy the legal assessor, yet it might enable the members of the Council to perform their duty.

Mr. LUSHINGTON: You may hand in the paper. No court or tribunal or body with judicial functions ever entertains the question judicially whether it is acting so as to prejudice itself or not. It cannot be a judge of that question. We will receive the objection. We will not have it argued and we will not have it read.

Mr. HEMMING: I am not asking the court whether it has been guilty of prejudice and bias. Owing to what has occurred my client has not had an opportunity of putting his case before the Council which he ought to have had by the Council's own rules. I take it something has been done in defiance of the Council's own rules and it has seriously prejudiced the defence of the accused practitioner who ought to have been heard.

Mr. LUSHINGTON: There I differ from you. That ought not to be heard.

He went on to point out that there was an overruling power for the Council constituted by the law of the land. He asked Mr. Hemming to hand in his objection and proceed to the next point.

Mr. HEMMING (continuing) said that it was his duty to object to the President presiding over the inquiry on the ground that he had presided over the Penal Cases Committee and there he might be assumed to have come to a conclusion with regard to the accused practitioner. This objection became the more evident on the score that Mr. Nicolas should have had an opportunity of placing his case before the Penal Cases Committee. It would follow, he thought, that the President had come to the conclusion that the evidence which had been placed before him was trustworthy and credible enough to bring the accused practitioner before the Council. This, he argued, disqualified the President from acting as a judge in the case against the practitioner. His client believed that he had a substantial complaint against the earlier conduct of these proceedings with regard to many points and he did not wish to have to appeal to Cæsar on it. Mr. Nicolas had not had the opportunity of repelling the attacks on his character which were promulgated behind his back, and on this ground the objection must be pressed with great anxiety and earnestness. It had been suggested to him that it was indiscreet to urge such reasons, and that it might prejudice his client's case. He refused to believe that any objection raised on proper grounds before English gentlemen would prejudice his client. He protested against the President presiding at the inquiry.

Mr. LUSHINGTON: There is nothing whatever in that objection and I shall advise the Council to that effect. I shall advise the President to continue sitting.

Mr. HEMMING: On the same ground I have got an objection to any member of the Penal Cases Committee sitting on the case.

Mr. LUSHINGTON also overruled this objection.

Mr. HEMMING further pointed out that by the rules of the Council no complaint should be considered by the Penal Cases Committee until a statutory declaration as to the facts of the case had been supplied by the complainant. He did not think the legal assessor would say that the complainant had furnished any such declaration. The complainant was the London and Counties Medical Protection Society. There was no statutory declaration and there could not be a statutory declaration by the London and Counties Medical Protection Society. There was a statutory declaration by Mr. Atkinson, and he ought to be the complainant. It did not answer the Council's rule that the complaint should be put forward by somebody else. Mr. Atkinson had made a declaration as to hearsay. Therefore, he contended, the proceedings could not be commenced before the Council until they had some responsible complainant.

Mr. LUSHINGTON: I understand that your point is that there is no statutory declaration as to the matter submitted by the complainant.

Mr. HEMMING: Yes.

Mr. LUSHINGTON: I overrule that at once because there are 30. He pointed out that the Council would try the case not only on the statutory declarations but on evidence to be submitted. He further asked Mr. Hemming whether, if his client had an absolute answer, it was worth while to claim any technical points.

Mr. HEMMING said that he understood he was not to be allowed to cross-examine Mr. Atkinson on certain points because legal proceedings were being taken in the King's Bench Division.

Mr. LUSHINGTON replied that Mr. Hemming's client having started an action for libel founded on two particular letters it became his duty to put an innuendo on these letters and to prove it. His ruling had been that Mr. Atkinson should not be cross-examined so as to furnish it. Mr. Atkinson had been examined, cross-examined, and re-examined in November. The present was not the time for raising the point but he would see that no improper question was put to Mr. Hemming's witnesses.

Mr. HEMMING asked that he might be allowed to continue his cross examination of Mr. Atkinson.

Mr. LUSHINGTON: That application is refused.

Mr. HEMMING proceeded to submit further objections. He claimed that the charge ought to be sufficiently clear to enable him to deal with it. He believed that the Council never informed an accused practitioner on what point a decision turned. The legal assessor had said that there was a court which could revise the proceedings of the Council. Surely there ought to be material to take before that court in order that the proceedings might be revised. In the charge the accused practitioner was charged with canvassing "by personal visits to patients of Mr. Thomas William Atkinson and to others." He would emphasise the words "and to others." If these words went before the King's Bench his client's representatives could not satisfy that tribunal that they did not form a part of the judgment. He therefore asked that these words should be amended as an indictment would be, before a judge in any court. He desired that the words "and to others" should be struck out.

Mr. LUSHINGTON replied that after what Dr. Woods, who had conducted the case in November, had said, Mr. Hemming might take it that no evidence would be tendered on that point; and further, that Mr. Nicolas was entitled to an acquittal so far as the charge that he had systematically canvassed in Catford for patients by personal visits to persons other than patients of Mr. Atkinson, was concerned. Mr. Hemming need not trouble himself further about that.

Mrs. MURPHY, now of Southampton but formerly resident in the Catford district, the wife of a builder, was then examined as a witness. She stated that she had been a patient of Mr. Atkinson and had met Mr. Nicolas, his assistant. She alleged that in 1907 Mr. Nicolas had called on her and told her that he had a *medical practice and would* be pleased to attend her.

Cross examined by Mr. Hemming, she denied that Mr. Nicholas came to discuss the price of a red lamp.

Mrs. REDNALL, a patient of Mr. Atkinson, alleged that Mr. Nicolas had stated to her that he was going to set up on his own. She further stated that Mr. Nicolas said: "We young doctors know all the new ideas coming from the hospital. The old doctors know nothing."

Miss E. ROSS, a professional nurse residing in Catford, was another witness. She had nursed Mr. Atkinson's cases and asserted that Mr. Nicolas had criticised and changed treatment prescribed by Mr. Atkinson.

Cross-examined, she admitted that perhaps half her cases were also those of Mr. Atkinson.

The Council postponed the further hearing of the case until the following day and then adjourned.

SATURDAY, MAY 30TH.

The Council resumed its sittings to-day. Dr. DONALD MACALISTER, the President, was again in the chair.

The Catford Case.

The hearing of evidence in connexion with the charge brought against Mr. John Papa Nicolas was resumed. Witnesses were heard in support of the charge.

Mrs. EDNY, Catford, alleged that Mr. Nicolas told her that his fees were less than *those* of Mr. *Atkinson.*

Mrs. SUSAN HART declared that Mr. Nicolas had told her Mr. Atkinson "was no good for *children*" and that he was one of the old school.

Dr. HEMMANS, *Lewisham Park*, was another witness. He knew Mr. Nicolas. On one occasion Mr. Nicolas had said to him that Mr. Atkinson was not likely to have a partnership for many years.

Cross-examined by Mr. HEMMING witness admitted that at *one* time he was *friendly* with *Mr. Nicolas. He* had a high opinion of Mr. Nicolas's professional *skill.*

Mr. G. LAWRENCE, *who stated that* he was a Member of the Royal College of Surgeons, was another witness. He said that he had been a partner of Mr. Atkinson since July, 1907. He had accompanied the Commissioner for Oaths when the statutory *declarations* in connexion *with the charge* were signed. The declaration in each case had been read over *to* the person signing it. It was deliberately read and in his opinion the people who signed understood what *they* were signing.

Cross-examined by Mr. HEMMING *he admitted that a libel* action was pending against him which was intimately connected with the matter *before the Council. He admitted* that the declarations were signed in the evening. Although 12 of them bore the same date *he denied that* undue haste had taken place or that the contents had been hurried over to the declarants before they signed them. He had asked patients of his and of Mr. Atkinson for evidence in regard to the case under consideration.

Mr. POUTER, Commissioner for Oaths, who was present at the signing of the statutory declarations, stated that the signatures had been obtained in the proper and *regular* way.

Several witnesses made statements in support of the charge, and they were minutely *cross-examined* by Mr. HEMMING *as to* the dates of the incidents which they alleged and as to points affecting the consist*ency* and credibility of their evidence.

Mrs. WICKS, one witness who had lost a baby, stated that Mr. Nicolas had told her that if she had brought it to him he could have saved it. She also alleged that he said that Mr. Atkinson had lost babies but he had not lost one.

Cross-examined by Mr. HEMMING she admitted that no third person was present when the alleged statement was made to her.

Mr. NEILSON said that he had called 13 witnesses in support of the charge, and he had 24 in addition to those whom he could call, but he declined to do so in the interests of all concerned. He therefore proposed to close his case subject to this. In November Dr. Woods, who was then in charge of the case, pledged himself to go into the witness-box. He could not say that Dr. Woods could give any relevant evidence on the matters at issue. Having given that pledge he felt sure comment *would* be made if Dr. *Woods did* not go into the witness-box.

Dr. HUGH WOODS entered the *witness-box* but was asked no questions by Mr. Neilson.

In answer to Mr. HEMMING he admitted that he had been to Catford in connexion with the case. He had gone down *to assure himself of the accuracy of some statutory declara*tions on which doubt had been cast, but he strongly denied that he had tried to influence witnesses. He had done nothing improper.

This closed the case in support of the charge.

Mr. HEMMING then opened the case for the defence. He submitted that no case had been made out as to there having been "*systematic canvassing.*"

Mr. LUSHINGTON ruled that there was a *primâ facie* case to go to the Council on the word "systematically."

Mr. HEMMING: I object to the charge because it is not in accordance with the rules of the Council.

Mr. LUSHINGTON: That also is overruled.

Mr. HEMMING: Even if the charge were proved I submit that it would not amount to *infamous conduct in a pro*fessional respect. The General Medical Council had defined the offences which came under the heading of canvassing and advertisement. What was not included in that definition must be excluded from it. The evidence, so far as it was trustworthy, could not amount to evidence *of* infamous conduct in a professional respect under the Medical Act. In view of the character of the witnesses and the hostility which they had shown there was no case whatever for him to answer with regard to infamous conduct in a professional respect. Here was a young practitioner who claimed to be entitled to practise where he was practising. He was opposed by an elderly gentleman. The Council had seen the character of the witnesses and seen how *easy it* was for an innocent expression to be twisted into something dangerous. He submitted again that this was not an instance where there was any case to go forward with.

Mr. LUSHINGTON said that he would advise the Council differently. The document which Mr. Hemming had just been alluding to was not law. It was a warning. It was for the Council to say upon the facts of each case as laid before them whether the conduct disclosed was or was not infamous conduct in a professional respect, quite apart from the question whether it came within the warning notice or not. The matter had been very well put in the Court of Appeal by the late Lord Esher. He had said: "If it is shown that a medical man in the pursuit of his profession has done something in regard to it which will be reasonably regarded as disgraceful or dishonourable by his professional brethren of good repute then it is open to the General Medical Council to say that he has been guilty of infamous conduct in a professional respect."

Mr. HEMMING then called evidence in defence of Mr. Nicolas.

Mr. BELLMAN, a druggist, stated that Mr. Lawrence had called on him and told him that Mr. Nicolas was trying to get his patients away.

Mr. HEMMING went into the witness-box and was granted leave to be examined by his clerk who was a qualified solicitor. He stated that in January, 1906, Mr. Nicolas had attended his wife. At that time he had asked Mr. Atkinson *as to* Mr. Nicolas's ability. Mr. Atkinson then could not say *anything too* extravagant in favour of Mr. Nicoles. He asked Mr. Nicolas what he thought of Mr. Atkinson and he spoke very handsomely of him. It had been stated that Mr. Atkinson's lowest confinement charge was a guinea. *He* had had an opportunity given him to examine Mr. Atkinson's books. The lowest midwifery *charges in them were 10s., 12s.*, and 15*s*.

Briefly cross-examined by Mr. NEILSON he said that it was alleged that Mr. Nicolas systematically canvassed Mr. Atkinson's patients. When he gave Mr. Nicolas an opportunity of disparaging Mr. Atkinson he praised him.

Mr. NEILSON: The amount of your evidence, I suppose, is that he did not canvass you.

Mr. HEMMING: He did not canvass me.

Mr. JOHN PAPA NICOLAS, against whom *the* charge was made, went into the witness-box. He stated his qualifications.

At this point his examination was postponed.

The Council adjourned.

MONDAY, JUNE 1ST.

The Council resumed its *sittings to-day, Dr.* DONALD MACALISTER, the *President*, being in the chair.

The Catford Case.

The Council proceeded with the further hearing of evidence in connexion with the charge against Mr. John Papa Nicolas, a report of which will be given in a later issue.

TUESDAY, JUNE 2ND.

The Council resumed its sittings to-day, Dr DONALD MACALISTER being in the chair.

The Business of the Council.

Dr. NORMAN MOORE at the outset of the proceedings said that Dr. Langley Browne, in view of the time that would necessarily be occupied with other business, had consented to withdraw his motion to the effect that "representations be made to the Privy Council that it is expedient to confer on the registered practitioners resident in England and Wales the power of returning an additional member to the General Medical Council." In view of the fact that some time would be required to discuss the matter adequately the motion would be postponed until the next session of the Council. There was a matter of urgency to which he had to allude. It referred to some questions with regard to the property of the Council. He suggested that the Office Site Committee, consisting of the President, the treasurers, and the chairman of the Business Committee, should be authorised to decide, when consulted by the solicitor, as to certain matters of urgency in regard to the letting of part of the Council's property.

A motion giving effect to this suggestion was adopted by the Council without discussion.

The Examination Committee's Reports.

On the motion of Dr. MCVAIL two reports by the Examination committee were formally received and entered on the minutes. The first refers to the final examinations held by the Apothecaries' Hall, Dublin, in January and April, 1908. It runs:—

The assistant examiners report, as regards the examination of Jan. 29th. 1908, that they "were satisfied with the manner in which this examination was conducted, and the standard of proficiency in medicine, surgery, and midwifery required from the candidates was sufficient and searching in every detail." Concerning the examination held on April 29th, 30th, and May 1st, 2nd, 1908, the assistant examiners "were satisfied with the manner in which the examination was conducted, and they considered that the standard of proficiency in medicine, surgery, midwifery, and ophthalmology was sufficient and searching in every detail." The assistant examiners supply copies of the written questions and give the results of the examination in each subject, with passes and rejections, but otherwise give no detailed information.

The second report referred to the analysis of the returns as to examinations for the services received since the last session of the Council.

No discussion took place on either.

Report of the Pharmacopœia Committee.

Dr. NORMAN MOORE moved that the report of the Pharmacopœia Committee should be received and entered on the minutes. The report was in the following terms:—

From Nov. 18th, 1907, to May 18th, 1908, the number of copies of the British Pharmacopœia (1898) sold by the publishers was 588. The total number of copies sold in the year beginning May 25th, 1907, was 1095. Up to the present time 39,769 copies of the Pharmacopœia and 4470 copies of the Indian and Colonial Addendum have been sold. A further impression of the Pharmacopœia having been ordered the stock on hand now consists of 3261 copies, together with 1894 copies of the Addendum. The Committee of Reference in Pharmacy have presented two reports, one containing suggestions for the revision of certain monographs of the Pharmacopœia (1898), the other containing the results of an analysis of 48,000 prescriptions actually dispensed by pharmacists in England, Scotland, and Ireland during the last year or so. Information has also been furnished by wholesale druggists and manufacturers regarding the unofficial drugs and preparations for which there is a large demand and regarding the official articles for which the demand has become very small. The details thus supplied by the Committee of Reference at the cost of much labour will be of material assistance to the committee in deciding on the inclusion in or omission from the next Pharmacopœia of particular articles.

In order that they might ascertain the views of the medical authorities regarding such inclusions or omissions, inquiries have been addressed by the President to the several licensing bodies in the United Kingdom. In response to these inquiries the Committee have received a large number of careful reports, prepared by special committees appointed by the bodies and sanctioned by their authority. The suggestions for the improvement of the Pharmacopœia therein contained will now be analysed and tabulated and will be considered by the committee in due course. The thanks of the committee and of the Council are due to all those who in this connexion have willingly assisted towards the production of a Pharmacopœia which will reflect faithfully the present state of medical and pharmaceutical science and practice.

The attention of the committee having been called to a recent publication which appeared to them to infringe the Council's statutory rights in the Pharmacopœia the opinion of counsel was taken on the subject. The opinion confirmed the view taken by the committee and suggested the proper steps to be taken for the Council's protection. Acting on the legal advice thus obtained representations were made to the publishers, with the result that the present issue of the publication has been stopped. Guarantees have also been furnished that future issues shall not be open to the like objection. In view of the legal sanction which the Pharmacopœia possesses, not only in the United Kingdom but in other parts of the empire, it is important that its official authority should be safeguarded, and that the statutory property in its text, which the Legislature has vested in the Council, should not be impaired by the publication and sale of unauthorised transcripts.

Sir JOHN MOORE seconded.

The motion was agreed to without discussion.

The Assistant Examiners to the Apothecaries' Hall of Ireland.

The Council resumed consideration of the report by the Executive Committee in regard to the duties of assistant examiners to the Apothecaries' Hall of Ireland. The Executive Committee submitted the following recommendations to the Council:—

1. That the examiners appointed by the Council to assist at the qualifying examinations held by the Apothecaries' Hall, Dublin, be instructed to conduct the surgical portion of these examinations; and, in addition, to supervise the medical and obstetrical portions, with the object of securing that at each qualifying examination the required standard of proficiency is maintained.
2. That the examiners be instructed to report fully, for the information of the Council, as to the methods and standards actually adopted at each qualifying examination, and as to the steps they have taken in fulfilment of the duties imposed upon them by Section 5 of the Medical Act, 1886.

The PRESIDENT moved that the recommendations of the Executive Committee should be adopted.

Dr. NORMAN MOORE seconded.

Dr. ADYE-CURRAN asked that the two recommendations should be put separately. One of them he considered legal but the other was not.

Sir THOMAS MYLES moved to amend the first recommendation so that it should read as follows:—

That the examiners appointed by the Council to assist at the qualifying examinations held by the Society of Apothecaries of London and by the Apothecaries' Hall, Dublin, &c.

He would not take up the time of the Council by speaking on his amendment.

Dr. SAUNDBY seconded the amendment.

Sir HUGH BEEVOR commented on the fact that no reasons had been given for the amendment and he knew no reason why there should be a change in the custom of the Council. The custom of the Council for many years had not been that there should be a report on the Apothecaries' Society of London. He did not see why there should be a departure from that custom. There was a very valid reason for a long time why the Apothecaries' Hall of Ireland should be examined. That was a matter of history long before his time, and the President was cognisant why this course had been followed in Dublin and not in the case of the Apothecaries' Society of London. He repeated that no change ought to be made.

Sir C. NIXON suggested that the discussion on this subject should be postponed until they had finished the penal business. He would like to say a few words in connexion with it.

Dr. ADYE-CURRAN said that he did not think that one side of the matter should be discussed and then the consideration postponed indefinitely. That might lead to fixing one side of the case only in the minds of members of the Council.

The discussion of the matter was then postponed.

The Dental Education and Examination Committee.

Mr. TOMES moved that the report of the Dental Education and Examination Committee should be received and adopted. The report dealt mainly with the refusal of registration as a foreign dentist to a Russian subject. It also stated that an inquiry as to reciprocity had been received from the Dental Council of Canada, which forwarded particulars of the requirements for its diploma. It appeared, however, that this was so far a voluntary combination and it did not appear that it had obtained any legislative recognition. Until this was obtained it would be impossible for the General Medical Council to take cognisance of its diplomas.

Mr. MORRIS seconded.

The motion was agreed to.

Unqualified Practice Prevention Committee.

Dr. LANGLEY BROWNE moved that the report of the Unqualified Practice Prevention Committee should be received and adopted. The report went on to state that through the good offices of the Lord President of the Council information desired with regard to unqualified practice abroad had been furnished. The report proceeded:—

Most countries make some attempt to regulate the existence of medical practice, to check unlicensed practitioners, and to confine the exercise of the healing art to members of their own nationality, or, at any rate, to those who have passed some medical examination in the country. These regulations vary very considerably, and seem to depend upon two main considerations: I. The more enlightened countries consider the question from the point of view of protecting the public from the dangers of unqualified practice by regulating the sale of poisons, dangerous drugs, &c., and put in the background the necessity of the practitioner being qualified according to their own colleges or universities. II. Other countries seem to regard it more as a means of exacting a fee for the privilege of practising, and to attach more importance to registration or licensing than to the qualification of the practitioner.

Germany alone leaves the practice of the healing art prefectly free so long as the practitioner does not assume certain titles and does not seek recognition by the municipal or police authorities. Should he desire to be recognised as a medical man or even as a veterinary surgeon he must obtain an "approbation," which is equivalent to a licence to practise and to assume such title to designate his specialty as he pleases. Italy is distinguished by the grant of a general permit to the properly qualified foreign practitioner to attend to his own countrymen, but this is a concession to the foreign population rather than to the medical profession, and practice among Italians is permitted only on obtaining an Italian diploma. With regard to the colonies, returns have been received from the Dominion of Canada and her ten provinces and from the three districts of South Africa. In Canada the disposition has been to acknowledge all good foreign degrees and especially to recognise the English register, but it is evident that with the growth of Canadian schools of medicine there is an increasing tendency to require a local examination, and as increased facilities for medical study extend westward this tendency is likely to increase.

At the present time the ambition of the Canadian practitioner is to come to England and obtain an English diploma in addition to his Colonial degree, but that is because so far the Universities of Canada do not seem to have been fully recognised; for instance, they are not named among the other colonial schools whose diplomas are recognised in the schedule to the Act in South Africa. With regard to the general question of penalty the recognised offences are as follow: Unqualified practice; unregistered or unlicensed practice; the illegal assumption of titles; the administration of poisons or other potent drugs; and want of proper skill in either qualified or unqualified practitioners. The conditions which prevail in Egypt are somewhat exceptional and special permission is given to the barbers to continue their practices, which are historical, and which include the rite of circumcision, bleeding, cupping, leeching, and vaccination.

The Egyptian Government appear to recognise any genuine diploma, and there seems reason to believe that great notice is taken of the administration of drugs and poisons; there is also a strong medico-legal department in Egypt which deals with unqualified administration of drugs, &c. It is not possible to attach much importance to the law in South America, as it would appear that, with the exception of Brazil, the question is regarded by the smaller States as rather fiscal than for public protection, and in such unsettled countries as Uruguay and Panama the methods adopted can hardly be seriously considered. The recognition of charity and religion as a cloak for unqualified practice prevails in Russia, and although no returns are here given it also exists among the protectorates of the northern littoral of Africa west of Egypt. Several countries appear from the details given to be in favour of reciprocity in admitting degrees of equivalent value, but no general consensus can be discovered. It may also be remarked that the most exacting country is Switzerland, which requires a complete examination from all who seek to practise even among foreign visitors.

The returns received from the Foreign Office and from the Colonial Office comprise the reports of 34 countries and six of our own colonies. Other returns have been received during the present week. Of these, Persia, Morocco, Zanzibar, and Abyssinia possess no regulations for medical practice; nor does the Empire of India. The conditions prevailing in the German Empire are exceptional. It would appear that so long as the would-be practitioner does not assume any title—e.g., physician, surgeon, oculist, dentist, obstetrician, &c.,—he may practise as much as he pleases. Some of the component States of the German Empire have made local regulations, but while returns are shown from Baden, Bavaria, Hesse, and Würtemburg, the conditions prevailing generally are set out in the despatch from the Foreign Office at Berlin.

The committees propose to continue their investigations and to report further at the next session of the Council.

Sir JOHN MOORE seconded.

The motion was agreed to without discussion.

The Students' Registration Committee's Report.

On the motion of Sir HUGH BEEVOR the report of the Students' Registration Committee was received and adopted.

Removals from the Register.

On the motion of Dr. LATIMER, seconded by Dr. SAUNDBY, a motion was agreed to that the Executive Committee should be requested to consider the report on the course to be followed in the case of practitioners who applied to be removed from the Medical or Dentists Register.

The Report of the Finance Committee.

Mr. TOMES moved the adoption of the report of the Finance Committee. This report showed that the income of the General and Branch Councils for the year ending Dec. 31st, 1907, was £8465 17*s.* 11*d.*, and the expenditure during the year was £7370 17*s.* 9*d.*, and consequently there was a surplus of £1095 0*s.* 2*d.* The report went on to say that this was very satisfactory indeed, bearing in mind that £235 6*s.* 11*d.* and £415 17*s.* 2*d.* respectively were written off the cost of office improvements and the enlargement of the Council chamber, and so appeared under the heading of expenditure. The receipts from fees were almost identical with those in 1906, for the small difference of £30 1*s.* 6*d.* less received by the branches was compensated by £30 more received by the General Council for colonial and foreign fees. The English Branch showed a large decrease of £265 under this head, but that was nearly wiped out by £195 13*s.* 6*d.* more received by the Scottish Branch, and £39 5*s.* more received by the Irish Branch.

Dr. LITTLE seconded the adoption of the report, which was agreed to without debate.

Appointment of Committees.

The following committees, among others, were appointed:—

The Examination Committee, consisting of Dr. Pye-Smith, Mr. Young, and Dr. Caton (nominated by the English Branch Council), Sir Thomas Fraser, Dr. Finlay, and Dr. McVail (nominated by the Scottish Branch Council), Dr. Kidd, Sir John Moore, and Sir Charles Ball (nominated by the Irish Branch Council).

The Education Committee, consisting of Dr. Norman Moore, Sir George Philipson, and Sir John Williams (nominated by the English Branch Council), Dr. Mackay, Sir John Tuke, and Dr. Lindsay Steven (nominated by the Scottish Branch Council), Sir Thomas Myles, Sir C. Nixon, and Dr. Little (nominated by the Irish Branch Council).

The Public Health Committee, consisting of Dr. Cocking, Mr. Power, and Dr. Langley Browne (nominated by the English Branch Council), Dr. Norman Walker, Dr. Lindsay Steven, and Dr. McVail (nominated by the Scottish Branch Council), Sir John Moore, Dr. Kidd, and Dr. Adye-Curran (nominated by the Irish Branch Council).

The Pharmacopœia Committee, consisting of the President, Dr. Norman Moore, Dr. Barrs, Sir John Moore, Sir G. Philipson, Sir Thomas Fraser, Dr. Little, Dr. Caton, and Dr. McVail.

It was also announced that the Executive Committee and the Penal Cases Committee had been re-elected without any change of *personnel.*

WEDNESDAY, JUNE 3RD.

The Council concluded its sittings this evening, and late in the day the decision in the Catford case was given against Mr. John Papa Nicolas, whose name was ordered to be erased from the Register for unprofessional conduct. An application was made by Mr. Hemming, Mr. Nicolas's solicitor, that the erasure should be postponed for a month in order that a writ of *certiorari* might be applied for.

LYNN THOMAS AND SKYRME FUND.

THE following subscriptions have been received between May 22nd and May 29th by Mr. William Sheen, M.S. Lond., F.R.C.S. Eng. (2, St. Andrew's-crescent, Cardiff), honorary secretary to the fund.

Subscriber of Two Guineas.

Russell Coombe, Exeter.

Subscribers of Two Pounds One Shilling.

Bolton Medical Society, per Douglas Gray, the amount being made up as follows:—

One Guinea from—

H. Jefferies, Bolton.

Five Shillings from—

F. Dowling, Bolton.
Douglas Gray, Bolton.
T. O'Neill, Bolton.
D. S. Sutherland, Bolton.

Subscribers of One Guinea.

Subscriber of Half-a-crown.

Thomas Du B. Whaite, Lieutenant-Colonel R.A.M.C., per L. D. Parsons, honorary secretary, Gibraltar Division, British Medical Association.

in connexion with the charge against Mr. John Papa Nicolas, a report of which will be given in a later issue.

TUESDAY, JUNE 2ND.

The Council resumed its sittings to-day, Dr DONALD MACALISTER being in the chair.

The Business of the Council.

Dr. NORMAN MOORE at the outset of the proceedings said that Dr. Langley Browne, in view of the time that would necessarily be occupied with other business, had consented to withdraw his motion to the effect that "representations be made to the Privy Council that it is expedient to confer on the registered practitioners resident in England and Wales the power of returning an additional member to the General Medical Council." In view of the fact that some time would be required to discuss the matter adequately the motion would be postponed until the next session of the Council. There was a matter of urgency to which he had to allude. It referred to some questions with regard to the property of the Council. He suggested that the Office Site Committee, consisting of the President, the treasurers, and the chairman of the Business Committee, should be authorised to decide, when consulted by the solicitor, as to certain matters of urgency in regard to the letting of part of the Council's property.

A motion giving effect to this suggestion was adopted by the Council without discussion.

The Examination Committee's Reports.

On the motion of Dr. MCVAIL two reports by the Examination committee were formally received and entered on the minutes. The first refers to the final examinations held by the Apothecaries' Hall, Dublin, in January and April, 1908. It runs:—

> The assistant examiners report, as regards the examination of Jan. 29th, 1908, that they "were satisfied with the manner in which this examination was conducted, and the standard of proficiency in medicine, surgery, and midwifery required from the candidates was sufficient and searching in every detail." Concerning the examination held on April 29th, 30th, and May 1st, 2nd, 1908, the assistant examiners "were satisfied with the manner in which the examination was conducted, and they considered that the standard of proficiency in medicine, surgery, midwifery, and ophthalmology was sufficient and searching in every detail." The assistant examiners supply copies of the written questions and give the results of the examination in each subject, with passes and rejections, but otherwise give no detailed information.

The second report referred to the analysis of the returns as to examinations for the services received since the last session of the Council.

No discussion took place on either.

Report of the Pharmacopœia Committee.

Dr. NORMAN MOORE moved that the report of the Pharmacopœia Committee should be received and entered on the minutes. The report was in the following terms:—

> From Nov. 18th, 1907, to May 18th, 1908, the number of copies of the British Pharmacopœia (1898) sold by the publishers was 588. The total number of copies sold in the year beginning May 25th, 1907, was 1095. Up to the present time 39,769 copies of the Pharmacopœia and 4470 copies of the Indian and Colonial Addendum have been sold. A further impression of the Pharmacopœia having been ordered the stock on hand now consists of 3261 copies, together with 1894 copies of the Addendum. The Committee of Reference in Pharmacy have presented two reports, one containing suggestions for the revision of certain monographs of the Pharmacopœia (1898), the other containing the results of an analysis of 48,000 prescriptions actually dispensed by pharmacists in England, Scotland, and Ireland during the last year or so. Information has also been furnished by wholesale druggists and manufacturers regarding the unofficial drugs and preparations for which there is a large demand and regarding the official articles for which the demand has become very small. The details thus supplied by the Committee of Reference at the cost of much labour will be of material assistance to the committee in deciding on the inclusion in or omission from the next Pharmacopœia of particular articles.
>
> In order that they might ascertain the views of the medical authorities regarding such inclusions or omissions, inquiries have been addressed by the President to the several licensing bodies in the United Kingdom. In response to these inquiries the Committee have received a large number of careful reports, prepared by special committees appointed by the bodies and sanctioned by their authority. The suggestions for the improvement of the Pharmacopœia therein contained will now be analysed and tabulated and will be considered by the committee in due course. The thanks of the committee and of the Council are due to all those who in this connexion have willingly assisted towards the production of a Pharmacopœia which will reflect faithfully the present state of medical and pharmaceutical science and practice.
>
> The attention of the committee having been called to a recent publication which appeared to them to infringe the Council's statutory rights in the Pharmacopœia the opinion of counsel was taken on the subject. The opinion confirmed the view taken by the committee and suggested the proper steps to be taken for the Council's protection. Acting on the legal advice thus obtained representations were made to the publishers, with the result that the present issue of the publication has been stopped. Guarantees have also been furnished that future issues shall not be open to the like objection. In view of the legal sanction which the Pharmacopœia possesses, not only in the United Kingdom but in other parts of the empire, it is important that its official authority should be safeguarded, and that the statutory property in its text, which the Legislature has vested in the Council, should not be impaired by the publication and sale of unauthorised transcripts.

Sir JOHN MOORE seconded.

The motion was agreed to without discussion.

The Assistant Examiners to the Apothecaries' Hall of Ireland.

The Council resumed consideration of the report by the Executive Committee in regard to the duties of assistant examiners to the Apothecaries' Hall of Ireland. The Executive Committee submitted the following recommendations to the Council:—

> 1. That the examiners appointed by the Council to assist at the qualifying examinations held by the Apothecaries' Hall, Dublin, be instructed to conduct the surgical portion of these examinations; and, in addition, to supervise the medical and obstetrical portions, with the object of securing that at each qualifying examination the required standard of proficiency is maintained.
> 2. That the examiners be instructed to report fully, for the information of the Council, as to the methods and standards actually adopted at each qualifying examination, and as to the steps they have taken in fulfilment of the duties imposed upon them by Section 5 of the Medical Act, 1886.

The PRESIDENT moved that the recommendations of the Executive Committee should be adopted.

Dr. NORMAN MOORE seconded.

Dr. ADYE-CURRAN asked that the two recommendations should be put separately. One of them he considered legal but the other was not.

Sir THOMAS MYLES moved to amend the first recommendation so that it should read as follows:—

> That the examiners appointed by the Council to assist at the qualifying examinations held by the Society of Apothecaries of London and by the Apothecaries' Hall, Dublin, &c.

He would not take up the time of the Council by speaking on his amendment.

Dr. SAUNDBY seconded the amendment.

Sir HUGH BEEVOR commented on the fact that no reasons had been given for the amendment and he knew no reason why there should be a change in the custom of the Council. The custom of the Council for many years had not been that there should be a report on the Apothecaries' Society of London. He did not see why there should be a departure from that custom. There was a very valid reason for a long time why the Apothecaries' Hall of Ireland should be examined. That was a matter of history long before his time, and the President was cognisant why this course had been followed in Dublin and not in the case of the Apothecaries' Society of London. He repeated that no change ought to be made.

Sir C. NIXON suggested that the discussion on this subject should be postponed until they had finished the penal business. He would like to say a few words in connexion with it.

Dr. ADYE-CURRAN said that he did not think that one side of the matter should be discussed and then the consideration postponed indefinitely. That might lead to fixing one side of the case only in the minds of members of the Council.

The discussion of the matter was then postponed.

The Dental Education and Examination Committee.

Mr. TOMES moved that the report of the Dental Education and Examination Committee should be received and adopted. The report dealt mainly with the refusal of registration as a foreign dentist to a Russian subject. It also stated that an inquiry as to reciprocity had been received from the Dental Council of Canada, which forwarded particulars of the requirements for its diploma. It appeared, however, that this was so far a voluntary combination and it did not appear that it had obtained any legislative recognition. Until this was obtained it would be impossible for the General Medical Council to take cognisance of its diplomas.

Mr. MORRIS seconded.

The motion was agreed to.

Unqualified Practice Prevention Committee.

Dr. LANGLEY BROWNE moved that the report of the Unqualified Practice Prevention Committee should be received and adopted. The report went on to state that through the good offices of the Lord President of the Council information desired with regard to unqualified practice abroad had been furnished. The report proceeded:—

> Most countries make some attempt to regulate the existence of medical practice, to check unlicensed practitioners, and to confine the

exercise of the healing art to members of their own nationality, or, at any rate, to those who have passed some medical examination in the country. These regulations vary very considerably, and seem to depend upon two main considerations: I. The more enlightened countries consider the question from the point of view of protecting the public from the dangers of unqualified practice by regulating the sale of poisons, dangerous drugs, &c., and put in the background the necessity of the practitioner being qualified according to their own colleges or universities. II. Other countries seem to regard it more as a means of exacting a fee for the privilege of practising, and to attach more importance to registration or licensing than to the qualification of the practitioner.

Germany alone leaves the practice of the healing art prefectly free so long as the practitioner does not assume certain titles and does not seek recognition by the municipal or police authorities. Should he desire to be recognised as a medical man or even as a veterinary surgeon he must obtain an "approbation," which is equivalent to a licence to practise and to assume such title to designate his specialty as he pleases. Italy is distinguished by the grant of a general permit to the properly qualified foreign practitioner to attend to his own countrymen, but this is a concession to the foreign population rather than to the medical profession, and practice among Italians is permitted only on obtaining an Italian diploma. With regard to the colonies, returns have been received from the Dominion of Canada and her ten provinces and from the three districts of South Africa. In Canada the disposition has been to acknowledge all good foreign degrees and especially to recognise the English register, but it is evident that with the growth of Canadian schools of medicine there is an increasing tendency to require a local examination, and as increased facilities for medical study extend westward this tendency is likely to increase.

At the present time the ambition of the Canadian practitioner is to come to England and obtain an English diploma in addition to his Colonial degree, but that is because so far the Universities of Canada do not seem to have been fully recognised; for instance, they are not named among the other colonial schools whose diplomas are recognised in the schedule to the Act in South Africa. With regard to the general question of penalty the recognised offences are as follow: Unqualified practice; unregistered or unlicensed practice; the illegal assumption of titles; the administration of poisons or other potent drugs; and want of proper skill in either qualified or unqualified practitioners. The conditions which prevail in Egypt are somewhat exceptional and special permission is given to the barbers to continue their practices, which are historical, and which include the rite of circumcision, bleeding, cupping, leeching, and vaccination.

The Egyptian Government appear to recognise any genuine diploma, and there seems reason to believe that great notice is taken of the administration of drugs and poisons; there is also a strong medico-legal department in Egypt which deals with unqualified administration of drugs, &c. It is not possible to attach much importance to the law in South America, as it would appear that, with the exception of Brazil, the question is regarded by the smaller States as rather fiscal than for public protection, and in such unsettled countries as Uruguay and Panama the methods adopted can hardly be seriously considered. The recognition of charity and religion as a cloak for unqualified practice prevails in Russia, and although no returns are here given it also exists among the protectorates of the northern littoral of Africa west of Egypt. Several countries appear from the details given to be in favour of reciprocity in admitting degrees of equivalent value, but no general consensus can be discovered. It may also be remarked that the most exacting country is Switzerland, which requires a complete examination from all who seek to practise even among foreign visitors.

The returns received from the Foreign Office and from the Colonial Office comprise the reports of 34 countries and six of our own colonies. Other returns have been received during the present week. Of these, Persia, Morocco, Zanzibar, and Abyssinia possess no regulations for medical practice; nor does the Empire of India. The conditions prevailing in the German Empire are exceptional. It would appear that so long as the would-be practitioner does not assume any title—e.g., physician, surgeon, oculist, dentist, obstetrician, &c.,—he may practise as much as he pleases. Some of the component States of the German Empire have made local regulations, but while returns are shown from Baden, Bavaria, Hesse, and Würtemburg, the conditions prevailing generally are set out in the despatch from the Foreign Office at Berlin.

The committee propose to continue their investigations and to report further at the next session of the Council.

Sir JOHN MOORE seconded.

The motion was agreed to without discussion.

The Students' Registration Committee's Report.

On the motion of Sir HUGH BEEVOR the report of the Students' Registration Committee was received and adopted.

Removals from the Register.

On the motion of Dr. LATIMER, seconded by Dr. SAUNDBY, a motion was agreed to that the Executive Committee should be requested to consider the report on the course to be followed in the case of practitioners who applied to be removed from the Medical or Dentists Register.

The Report of the Finance Committee.

Mr. TOMES moved the adoption of the report of the Finance Committee. This report showed that the income of the General and Branch Councils for the year ending Dec. 31st, 1907, was £8465 17*s*. 11*d*., and the expenditure during the year was £7370 17*s*. 9*d*., and consequently there was a surplus of £1095 0*s*. 2*d*. The report went on to say that this was very satisfactory indeed, bearing in mind that £235 6*s*. 11*d*. and £415 17*s*. 2*d*. respectively were written off the cost of office improvements and the enlargement of the Council chamber, and so appeared under the heading of expenditure. The receipts from fees were almost identical with those in 1906, for the small difference of £30 1*s*. 6*d*. less received by the branches was compensated by £30 more received by the General Council for colonial and foreign fees. The English Branch showed a large decrease of £265 under this head, but that was nearly wiped out by £195 13*s*. 6*d*. more received by the Scottish Branch, and £39 5*s*. more received by the Irish Branch.

Dr. LITTLE seconded the adoption of the report, which was agreed to without debate.

Appointment of Committees.

The following committees, among others, were appointed:—

The Examination Committee, consisting of Dr. Pye-Smith, Mr. Young, and Dr. Caton (nominated by the English Branch Council), Sir Thomas Fraser, Dr. Finlay, and Dr. McVail (nominated by the Scottish Branch Council), Dr. Kidd, Sir John Moore, and Sir Charles Ball (nominated by the Irish Branch Council).

The Education Committee, consisting of Dr. Norman Moore, Sir George Philipson, and Sir John Williams (nominated by the English Branch Council), Dr. Mackay, Sir John Tuke, and Dr. Lindsay Steven (nominated by the Scottish Branch Council), Sir Thomas Myles, Sir C. Nixon, and Dr. Little (nominated by the Irish Branch Council).

The Public Health Committee, consisting of Dr. Cocking, Mr. Power, and Dr. Langley Browne (nominated by the English Branch Council), Dr. Norman Walker, Dr. Lindsay Steven, and Dr. McVail (nominated by the Scottish Branch Council), Sir John Moore, Dr. Kidd, and Dr. Adye-Curran (nominated by the Irish Branch Council).

The Pharmacopœia Committee, consisting of the President, Dr. Norman Moore, Dr. Barrs, Sir John Moore, Sir G. Philipson, Sir Thomas Fraser, Dr. Little, Dr. Caton, and Dr. McVail.

It was also announced that the Executive Committee and the Penal Cases Committee had been re-elected without any change of *personnel*.

WEDNESDAY, JUNE 3RD.

The Council concluded its sittings this evening, and late in the day the decision in the Catford case was given against Mr. John Papa Nicolas, whose name was ordered to be erased from the Register for unprofessional conduct. An application was made by Mr. Hemming, Mr. Nicolas's solicitor, that the erasure should be postponed for a month in order that a writ of *certiorari* might be applied for.

LYNN THOMAS AND SKYRME FUND.

THE following subscriptions have been received between May 22nd and May 29th by Mr. William Sheen, M.S. Lond., F.R.C.S. Eng. (2, St. Andrew's-crescent, Cardiff), honorary secretary to the fund.

THE LANCET.

LONDON: SATURDAY, JUNE 6, 1908.

The French Hospital and the "Entente."

FEW conditions could more aggravate the pains and perils of sickness than that they should be suffered among strangers in a foreign land; and few charities can have greater claims upon the benevolent than those which seek to surround such sufferers, as completely as may be possible, with the accents of the tongue which takes them back to the days of their childhood and with the innumerable *petits soins* which may recall memories of home. The hospitals which have been established in London for the treatment of the members of foreign nationalities have always seemed to us to be eminently worthy of the support, not only of the members of those nationalities who may be settled amongst us, but also of our own people; and the PRESIDENT of the French Republic could have done nothing more worthy of his high station, or of the great nation which he represents, than to withdraw himself for a time from the honours and festivities with which he has been received and to devote the leisure thus obtained to a visit to the French Hospital in Shaftesbury-avenue and to the practical display of his sympathies with the humblest of the population under his rule. It is pleasant to read in the reports of his visit that during its course "laughter sometimes rippled through the wards," and there can be little doubt that Sister-Superior CÉLINE was justified in the expectation which she expressed—that his coming would be "better than medicine" for many of those under her care. The patients, moreover, would be rejoiced at the official recognition of her long and faithful services by the Cross of Merit with which the PRESIDENT personally decorated her, as well as by the decorations conferred on some of the officials of the institution, and there can be no doubt that the day and the event will be long remembered as things of mark in the history of the institution. President LOUBET, when he was in London five years ago, paid a similar visit; but the steady subsequent growth of friendship between the two nations has added greatly to the importance of the Presidential action in English eyes; and we cannot but hope that it will also add to the substantial recognition of the French Hospital as a charity eminently worthy of our good wishes and of our efforts to give effect to them. The histories of medicine and of surgery owe much to France, and we can make no more graceful recognition of our debt to her than by provision that those of her children who are sick and suffering in our midst shall be surrounded with such care as may best promote their recovery.

The French Hospital, like many other excellent institutions, has grown to its present estate from small beginnings. It was in the first instance established as a dispensary by the late Dr. VINTRAS, a highly respected member of the French colony in London; and in 1867, after six years of eminently useful work, its doors were opened as a hospital with a modest equipment of 16 beds, increased in the following year to double that number by the absorption of an adjoining house. The demands upon its space continuing to increase, the French colony in London set themselves energetically to work to establish an institution worthy of their nationality, with the result that the present hospital was built and was opened in 1890 by the Ambassador, M. WADDINGTON. Since then two adjacent houses have been secured, one as a home for the nurses and the other as an infirmary for cases of pulmonary tuberculosis, so as to keep them from mixing with other classes of patients; and the total number of beds now amounts to 82. The management justly prides itself upon the economy of management in respect of which the French may fairly claim to offer an example to all other nations, and it is announced that the absolute cost of food for the patients amounts only to about one shilling (1fr. 25c.) per head per day. Nor is the economy obtained by any sacrifice of things still more essential, for the management quotes from the report made to King Edward VII.'s Fund by the visitors, Sir TREVOR LAWRENCE and the late Mr. MACNAMARA, a passage in which they "desire to express their admiration of the organisation, and of the order which reigns throughout." They further declared the hospital to be a model of what an institution of the kind ought to be and to leave nothing to be desired. It still failed, nevertheless, in meeting two urgent demands, a place of recovery for convalescents and a home for aged people who were no longer able entirely to maintain themselves; and in these respects it was rendered complete by the establishment and subsequent enlargement of the affiliated institution at Brighton, now containing 60 beds for convalescents and for the aged, beds with which the names of M. PAUL CAMBON, the Ambassador, and of M. et Mme. RUFFER are permanently associated. The French Government, too, justly mindful of the claims of those of its subjects who were assisting to maintain the commercial and industrial intercourse with England, to which both nations owe so much, has from the first been a munificent contributor to the cost of erecting the necessary buildings.

Few events in history, we think, are likely to act more beneficially or to exert a more powerful influence in the direction of peace and civilisation than the friendship between France and this country which is now a happily established fact and which restores the two nations to their proper places in relation to each other. The contemporaries of NELSON and of WELLINGTON were full of an animosity towards France which has long passed away and which it is only worth while to recall in order to point out its completely artificial and accidental character. The wars by which it was fed were not so much wars against France as against a striving for universal empire on the part of NAPOLEON—a strife in which a gallant nation had suffered itself to be led away from its better and earlier traditions by dreams of so-called "glory." We shall not estimate correctly the events thus arising or appreciate their really transitory character unless we remember how the soldiers of ELIZABETH and of HENRI IV. fought side by side against the somewhat similar dreams of empire of PHILIP of Spain, and how completely France in those days had been at one with us in the defence of civil and religious liberty against a despotism. She fought against us in the days of WILLIAM III. and of ANNE, but the struggle was of the same character as that with NAPOLEON, and England opposed the ambition of LOUIS XIV. as strenuously as she afterwards opposed that of the Empire. The true position of France in Europe is so great and her influence, when rightly used, must be so enormous that those who have striven to restrain this power and influence within their natural bounds should be regarded as her friends rather than as her enemies, and as having contributed to the consolidation of her empire rather than to any curtailment of her legitimate ambitions. At the present time, if undue ambition is to be feared on the part of any country, it is certainly not in France that it must be sought, and we have every reason to expect that our friendship with her and with her allies may exert a potent influence in restraining it, if it should exist, within those legitimate *spheres of operation* which are provided by the victories of peace, by the rivalries of inventors, by the efforts of the wise to bring about the increase and the diffusion of knowledge. The visit of the PRESIDENT of the Republic to this country has set the seal of his authority upon the growing friendship of two great nations, and his visit to the French Hospital was a fitting testimony of the care which in these enlightened days it so well beseems the great to extend towards the lowly. The English Hospital in Paris and the French Hospital amongst ourselves should afford to the benevolent of both countries additional opportunities of fostering relations by which both have much to gain and which to both are likely to be "twice blessed."

◆

The Local Government Board of Scotland and Public Abattoirs.

DR. FREDERICK DITTMAR, medical inspector to the Local Government Board of Scotland, has drawn up an official report on the provision of public slaughter houses by local authorities and the methods of meat inspection. Though this report is followed by suggestions for improvement[1] it shows very clearly that Scotland is far in advance of England in this important matter. It is satisfactory to find in this report an official endorsement of the principles for which we have contended in these columns since we took a leading part in the campaign against the inefficient control of the meat-supply. In the very first paragraph the report urges that not only the carcass but also the internal organs should undergo an examination "by an expert" before the flesh is placed on the market and offered for food. It will be remembered that some time ago the German authorities refused to admit into Germany the carcasses of cattle slaughtered in England unless the viscera remained attached so that the veterinary inspectors could make a full and proper examination. To insure such efficient inspection the report of the Local Government Board of Scotland insists, first, that animals "should be slaughtered in places under public control"; and secondly, that persons who decide as to fitness for human food should have no *interest to serve other than that of protecting the consumer.* Consequently they should be employed by, and paid by, "a public authority only"; and "private slaughter-houses, therefore, should be abolished and their place be taken by slaughter-houses under public control." The only exception admitted to this rule is in regard to such scattered communities as the crofters and fishing populations of the Western Highland and the Islands of Scotland. But the beauty of these fine pronouncements rests in the fact that in Scotland this is not merely theoretical. We are told that slaughter-houses belonging to town councils existed in several of the older burghs "almost from time immemorial." Of recent years a number of local Acts have been obtained authorising public slaughter-houses in nearly all the larger towns and many of the smaller burghs. The city of Edinburgh slaughter-house was built in 1851 and since 1865 private slaughtering has been illegal in Glasgow. Dundee had a public slaughter-house in 1876, Falkirk before 1885, Leith in 1863, and Kirkcaldy "from time immemorial." Altogether, out of the 205 burghs of Scotland 60·48 per cent., or 124, of these have public abattoirs. Of course, this represents a much larger proportion of the population as, with the exception of Aberdeen, it is the most populous burghs that have abattoirs. Again, though there are burghs that have no abattoirs this does not mean that they have private slaughter-houses. At Govan and similar burghs on the outskirts of Glasgow and other large towns they do not kill at all but fetch their meat from the public abattoir of the neighbouring town. And so the official report is able to state that from 88 to 90 per cent. "of the total burghal population of Scotland is provided with home-killed meat from slaughter-houses under public control."

These are facts and figures which should rouse the authorities in England and Ireland. If the latter country has the excuse of poverty for lagging behind this cannot be said of England. In Scotland, even in rural and sparsely populated districts, several very poor localities have been grouped together so that they might have a public abattoir between them. For instance, the Upper Deeside district of Kincardineshire and the burgh of Banchory, though their joint population only amounts to 1475 inhabitants, agree to share in the erection of a public abattoir. It would appear that there are 138 abattoirs in Scotland under public control and nine of these are in purely rural districts. These supply 90 per cent. of the population of the towns, or about 2,500,000 people. 340,644 people, or 11·5 per cent. of the town populations, obtain their meat from 154 private slaughter-houses situated in 63 burghs, and there are 563 private slaughter-houses in purely rural districts, with a total population of 1,500,000. Similar statistics in regard to England would constitute a humiliating comparison. In "Our Slaughter-House System," Mr. C. CASH, the author, only succeeded in obtaining information from less than two score English public abattoirs, and even where these existed the private slaughter-houses had not been all abolished. Yet, on the other hand, it would be altogether erroneous to conclude that all is perfect in Scotland. On the contrary, the main purpose of the official publication before us is to show the necessity of further reform. The report urges that no animal should be killed privately if the meat is to be placed on the market. At present pigs intended for curing are generally killed at the place of feeding, on the ground that "driven pork" does not cure well. But this obstacle can be overcome by the provision of sufficient lairage to enable the pigs to rest a few days after their journey and before they are killed. The report then demands that all towns should be compelled to have public abattoirs and that the plan of such structures should be first submitted for approval to the Local Government Board. The cost of construction and upkeep forms a legitimate charge against the public health rate of the district, but excepting in very sparsely populated rural districts the revenue would always prove sufficient to cover the outlay. To make a public abattoir pay, the law, it is suggested, ought to forbid the erection of any other private or public slaughter-house within a fixed radius, for instance, of five miles from a town which has only from 6000 to 8000 inhabitants. In districts where there are no slaughter-houses there should be travelling meat inspectors and the killing of animals intended to be sold for food should take place in the presence of such inspectors. An inspector, if not a veterinary surgeon, ought to have passed the examination held by the Royal Sanitary Institute. A special code should be issued so as to establish throughout the country a uniform standard of meat inspection. Then more energetic measures are needed to prevent the importation of meat. A half-carcass cannot be satisfactorily examined and boned meat cannot be examined at all. On this subject the report says:—

---

[1] Our Glasgow correspondent summarises these suggestions in our letter from Scotland this week.

> It has already been pointed out that the examination of dead meat can, under no circumstances, be fully satisfactory, as the internal organs, in which evidence of disease is so largely found, are necessarily absent. The Government of this country should therefore be satisfied of the thoroughness of inspection at the time and place of slaughter and before the meat is exported to this country.

Such are some of the requirements put forward by the Local Government Board of Scotland, and the Scotch are to be congratulated on the fact that they are very much in advance of the English. It is not too much to ask that we in England should have an early opportunity of enjoying similar benefits. As for London, it is needless to say that the metropolis is not only behind Scotland but is not on a level with some of the smaller English provincial towns. Perhaps the Blue Book just published may help to awaken the English public to a keener appreciation of what is urgently needed in this country.

Medical Missions.

"IMPERIAL expansion" has its appropriate celebration in "Empire Day," and among the contributory forces leading up to the former and worthy of due commemoration on the latter is ~~that of the Medical Mission.~~ What that force has been, particularly in the later decades of the nineteenth century, can best be indicated by the word "circumspice." Wherever Great Britain has established a "sphere of influence" in regions savage or semi-civilised, tropical or subtropical, there she can point to the concurrent establishment of the means of rehabilitation, social and moral, prominent in which stands out the Church mission, reinforced by the medical coadjutor as its "right-hand arm." Eloquent illustration of this fact has just been given in Edinburgh at the General Assembly of the United Free Church, whose moderator for the year is the Rev. ROBERT LAWS, M.D., a worthy successor in that chair of the Rev. JAMES STEWART, M.D., honourably associated with himself in the construction and consolidation of Livingstonia, that great bulwark of British power and prestige in Central Africa. On the occasion of his appointment to the post of Moderator an esteemed correspondent of THE LANCET[1] commented on Dr. LAWS's career in the medico missionary field and gave a forecast of the light which he might be expected to throw on the present and future of that "civilisade" (to use JOHN STUART MILL'S appropriate coinage). That forecast has been amply verified. The "mission," wherever initiated, has been successful in the degree in which it has utilised its medical arm, a policy and a method of "opening the door" of which Dr. LAWS is himself a typical exemplar and expositor. "It is," he said, "a trite piece of history now that PARKER led the way for the Gospel into China with the point of his lancet," while for gaining an entrance into Mahomedan regions no method has been found so effective. This, he proceeded to prove, was seen in the experience of Dr. PATERSON and his colleagues in the work at Hebron, where, received at the outset with curses as enemies, they "were now welcomed with blessings as trusted friends." Nay, more. In the Livingstonia Mission "one remarkable feature had been that all their stations, with the exception of one, had been begun by the medical missionary, and, in the case of that exception, rapid advance took place only after his advent." So much for medico-missionary work if looked at in its broad general effects. But those effects are the outcome, the aggregate, of the work bestowed on individuals. "It was," he says, "the physical need of the individual patient, and the treatment of this need that opened the door to the individual heart with its need of that Gospel which the missionary brought."

In this way, as in every other missionary effort, "the treatment of the individual which, by GOD'S blessing, led to his conversion, added one to the Church, and when this becomes co-extensive with the population there was not only a Christian Church but a Christian tribe or nation." Dr. LAWS continued his exposition of the success that waited on missionary labour when medically reinforced by an eloquent tribute to the educational coadjutor who follows in the track so prepared—the whole system adequately supported and encouraged being conducive to that "Imperial expansion" which is the envy of Great Britain's contemporaries, far behind as those are in the enlightenment and philanthropy of their methods, and in the same proportion inferior in the impression which they produce on the tribe or population under treatment. Not that the medico-missionary is a civilising agent peculiar to the English-speaking world.

As already pointed out, the Portuguese and the Italians, even so far back as the first post-Reformation decades, were pioneers in missionary exploration and evangelising, aided by skill in the healing art; while the noble work of the Capuchin MASSAIA in the Galla country, of which (with its extinction of small-pox and the consequent triumph of his mission) a vivid account is given in the publication

---

[1] THE LANCET, Nov. 30th, 1907, p. 1550.

(Rome, 1895) of the "Missionari Catholici Italiani," must ever remain in our memories. But even those efforts—and particularly this last—lacked the systematic support and the "staying power" characteristic of Anglo-Saxon enterprise, and they remain rather as evidence of "the might have been" than of the *fait accompli.* With such examples of failure, past and contemporary, Great Britain will have herself to blame if she does not keep in the van of "Imperial expansion" so auspiciously begun, so fraught with future augury, if she does not vouchsafe all encouragement and support to the efforts, in which her various Churches compete in honourable rivalry, for the rehabilitation of her ever-increasing subject-races by the methods so conspicuously successful of the medico-missionary organisation.

Annotations.

"Ne quid nimis."

THE STANDARDISATION OF TETANUS ANTITOXIN.

IN a United States Treasury Bulletin[1] Dr. Milton J. Rosenau and Dr. John F. Anderson describe the American method of standardising tetanus antitoxin and compare it with the German method described by Behring, the French method of Roux, and the Italian method after Tizzoni. They state that the European standards are admitted to be unsatisfactory and for the most part inaccurate, further that they are complicated and difficult to carry out. The American method is the result of several years' work in the Hygienic Laboratory and it is believed that it will commend itself for its simplicity, directness, and accuracy. The standard toxins and antitoxins are preserved under special precautions to prevent deterioration and are tested against each other reciprocally so that the least alteration in either may be detected. The unit is based upon the neutralising value of an arbitrary quantity of antitoxic serum but the antitoxin is not issued to other laboratories for the purpose of control, as is the case with diphtheria antitoxin. All the tetanus antitoxic serums for use in man upon the American market are now measured against a stable, precipitated tetanus toxin, the test dose of which has been carefully determined. Before the establishment of the American standard the tetanus antitoxins upon the market varied widely in the unit strength claimed for them and were for the most part comparatively weak in antitoxin potency. The American official immunity unit for measuring the strength of tetanus antitoxin is ten times the least quantity of antitetanic serum necessary to save the life of a guinea-pig weighing 350 grammes for 96 hours against the official test dose of a standard toxin furnished by the Hygienic Laboratory. In other words, one-tenth of a unit of the antitetanic serum mixed with 100 minimal lethal doses of the standard toxin contains just enough free poison in the mixture to kill the guinea-pig in four days after subcutaneous injection. The antitoxic serum for the purposes of this standard was obtained from a single horse. The serum was dried, powdered, and preserved in vacuum tubes under the influence of pentaphosphoric acid, in darkness, at a temperature of 5° C. While the antitoxin so prepared is stable, duplicates are made from time to time so as to guard against loss or change and to insure the permanence of the standard. In order to obtain trustworthy and comparable results it is necessary to take into account all the factors concerned, including the composition of the poisons, their concentration, the diluting fluid, the length of time during which the mixtures are allowed to stand, the site of inoculation, and other factors. All the known factors have been considered in devising this method of standardising tetanus antitoxin which is described in detail in the Bulletin. The necessity for an accurate standard is shown by a table representing the differences in potency and in the methods of testing tetanus antitoxin before the adoption of the American unit. It is now well known that when the symptoms of tetanus have developed the toxin has combined with the motor nerve cells and that the union between the cell and the poison is too strong for the antitoxin to break up. But if the antitoxin is given in time the toxin is neutralised and rendered harmless. Tetanus antitoxin is therefore an exceedingly valuable prophylactic and for this purpose it is coming into more general use in human and in veterinary practice.

THE MIDDLESEX HOSPITAL AND CANCER RESEARCH.

THE weekly board of the Middlesex Hospital reported to a recent meeting of the court of governors that a special committee had been established which will have for its sole object the promotion of the interests of the Cancer Charity and the collection of such sums as shall place the advance of the research work beyond the impediment of pecuniary anxiety. An urgent public appeal is being made for funds to meet the expenses of the current year, £1000 of the requisite £2500 having been already subscribed. At the same court, which was presided over by Field-Marshal Lord Grenfell, Major-General Lord Cheylesmore, C.V.O., moved the adoption of the hospital's report, which was seconded in a very able speech by Mr. A. Pearce Gould. This was largely directed to warning those who were interested in the Cancer Research Fund against becoming disheartened by the comparative slowness and the apparent insignificance of the steps which it was making in its advance against the hidden strongholds of malignant disease. He pointed out the necessity of the patient and laborious collection of facts bearing upon every side of the question as being the sure foundation upon which successful treatment of the disease must ultimately rest. In this connexion he adduced the recent reopening of a lying-in ward at the Middlesex Hospital, saying that it was a demonstration of the advance in the knowledge of another dread disease—puerperal fever—the prevalence of which in hospitals not so many years ago had made such wards simply disastrous for their inmates. The benefits which poor parturient women now infallibly derived from them were due entirely to the anxious, persistent, and devoted investigation in the laboratory which had revolutionised the whole practice with regard to midwifery. He confidently looked forward to an equally signal victory over cancer which would be attained by similar means. We agree with Mr. Gould that patient research will ultimately solve the problem, but we are not without hope that some investigator may arise who will be possessed of the true scientific imagination to reduce a thousand isolated facts into the compass of apparent law, the enunciation of which will suggest further investigations for its verification until the inner heart of the mystery is laid bare. It is only once in several generations that a genius arises who could, for instance, be led directly from a crystallographic study of tartaric acid to the elucidation of the causes of puerperal septicæmia by sheer scientific insight, but the conquest of cancer awaits such a one as Pasteur and we would fain believe that he will appear in this country. Meanwhile the continued minute study of the natural history of cancer by every means at our disposal is worthy of the fullest measure of support, and, indeed, the money already expended has been justified by its first fruits, for Mr. Gould was able to tell his supporters that notably in the electrical department in a large number of cases great good had been done to the poor patients suffering from cancer who went to the Middlesex Hospital for relief.

INSTANTANEOUS RADIOGRAPHY.

AN interesting demonstration was given on this subject at the London Hospital on May 27th last when very satisfactory radiographs were made of some cases of aneurysm in from one-fifth to half a second. While so-called instantaneous radiographs were made some years ago by several workers it was not until quite recently that the method has been so far perfected that it could be adopted as a regular procedure and it is chiefly due to Dr. Graedel of Nauheim that it has been brought within the sphere of every-day radiography. It may surprise some to find that very little modification of their existing x ray apparatus is necessary so long as a high voltage continuous current is available. The best results are obtained with the 200 volt to 250 volt current from the main. A very large primary current is used, sometimes as much as 90 ampères, through a special triple anode electrolytic interrupter. There is no danger to existing cables, fuses, and so on, owing to the very short time during which the current is flowing, and for the same reason the x ray tubes are not damaged, though the current through the latter may be from 20 to 50 milliampères or more. While excellent results are obtained with the tube, say, 24 inches from the plate, good results are also obtained at a distance of 80 inches and in this case there is so little distortion that the parts are represented at almost exactly their natural size—so nearly so that an orthodiagraph is unnecessary. This and the convenience of dealing with fretful and fidgety patients, such as children, make this new modification one of considerable value. While no doubt all makers of x ray apparatus will be supplying outfits specially designed for this work it is only fair to state that it has been first introduced into this country by Mr. K. Schall, and that it was in the factory of the firm of which he is a member that the technical details were worked out. The firm also provided the apparatus used in the demonstration at the London Hospital.

THE NECESSITY FOR OBTAINING THE PATIENT'S CONSENT TO OPERATION.

THE necessity for obtaining the patient's consent to operation may seem too obvious to require discussion, but cases in which the question is not so simple as might be imagined occur from time to time. In the *Cleveland Medical Journal* for May Professor Alfred Olum has discussed some cases which are of considerable interest. In Minnesota a patient consulted an aural surgeon for deafness of the right ear. There were a large perforation in the lower portion of the membrana tympani and a polypus in the middle ear. The surgeon advised operation, to which the patient consented. At the latter's request his family physician was present at the operation. When the patient was under the anæsthetic the surgeon examined his left ear and found that it was in a more serious condition than the right and in greater need of operation. He found a large perforation high in the membrane and the bone of the inner wall of the middle ear necrosed. He called the attention of the patient's physician to the condition and recommended that the operation should be performed on the left ear. To this no objection was made. The patient had not complained of any deafness in this ear or known of any trouble in it. The operation was successfully performed but after it the hearing of the left ear was seriously impaired and the patient brought an action for assault and battery against the surgeon. The court held that the operation was a violation of the rights of the patient unless the surgeon could show that the patient had explicitly or implicitly consented to an operation on the left ear. The jury returned a verdict for the plaintiff. In another case a woman the subject of epilepsy consented to some minor operation on the pelvic organs which took place in hospital. She left the hospital saying that she would consent to no further operation. She was induced to return and a major operation was performed. An internal organ (not specified) was removed. There was some evidence that the anæsthetic for the operation was administered to the patient when she was asleep. The surgeon testified that her husband had given his consent to the second operation. The court held that whether such consent was obtained or not was unimportant, because the wife's consent was necessary. A verdict was given for the plaintiff with exemplary damages—$3000. On appeal the verdict was upheld and the court regarded the operation as a mutilation which the surgeon had no right whatever to perform. This case is the precedent in the American courts that the consent of a husband is no legal substitute for the consent of his wife when she is the subject of operation.

THE APPOINTMENT OF POLICE SURGEONS FOR EDINBURGH.

THE *Scotsman* recently contained a letter over the initials "A. W." concerning the rates of pay which the town council of Edinburgh is offering to the police surgeons who are to be appointed to the districts of the city. According to him the highest salary is to be £80, the lowest £15, and the average about £50. The duties, he says, are onerous enough, including a daily visit to the police-station, attention to prisoners, sick constables, and so on. He not unnaturally asks the town council whether it regards wages below those of a scavenger as suitable for the remuneration of educated professional men. "A. W." further asks what a trade union would say to such a scale of pay and we must answer him that medicine is in the hands of a liberal profession in this country and not of a trade union, although this may offer cold consolation to those ground under the iron heel of unfair contract practice. This case at Edinburgh, however, seems to be one for which some remedy might be found by the united action of the medical practitioners in the neighbourhood of the various districts concerned, and an effect might even be produced by individual representations to some of those councillors who have the control of the public purse-strings, which, according to the *Scotsman's* correspondent, are opened liberally enough in respect of the salaries of other officials or in the cause of "municipal banquets and miscellaneous entertainments."

THE BOMBAY MEDICAL CONGRESS.

WE desire to call the attention of all our readers who are interested in Indian medical affairs and tropical medicine to an announcement which appears in our advertisement columns of a Medical Congress which will be held in Bombay in the early part of next year. His Excellency the Governor of Bombay will preside over the congress, and amongst the vice-presidents will be the members of his council, the Director-General of the Indian Medical Service, the Principal Medical Officer H.M.S. Forces in India, the Surgeon-General with the Government in Bombay, the Senior Medical Officer of the Royal Navy in Bombay, the Principal Medical Officer of H.M.S. Forces, Poona Division, and representative native medical practitioners. The general secretary and editor of the Transactions will be Lieutenant-Colonel W. E. Jennings, I.M.S., and the central committee consists of representatives of the official and non-official branches of the medical profession in India. The special objects of the congress will be the consideration of tropical diseases and sanitation as applied to India; the session will extend over four days and the subjects will be considered in six sections—namely: I., Cholera, Dysentery, Enteric Fever, and Tropical Diarrhœa; II., Malarial Fever, Plague, Leishman-Donovan Body Invasion, and Relapsing Fever; III., Parasitic Insects, Snake Venom, Beri-beri, Mycetoma, Elephantiasis, and Leprosy; IV., Sewage Disposal in India, Water Supplies, Disinfection, and General Sanitation; V., Ophthalmic Surgery Urinary Calculi, and Miscellaneous Papers on Tropical Surgery; and VI., Exhibition of Pathological Specimens and Lantern Slide Demonstration. In view of the great advances which are being made by the sanitary service of India we have no doubt that the forthcoming congress will be productive of very useful results for that and other tropical countries, and we trust that the profession in England will avail itself of the general-secretary's invitation to contribute papers for the consideration of the central representative committee.

THE FORMATION OF A MEDICAL BENEVOLENT SOCIETY FOR THE EAST AND NORTH RIDINGS OF YORKSHIRE.

IN the East and North Ridings of Yorkshire although the need has long been felt of such a society and the question of its formation has been raised on many occasions it is only recently that any definite action has been taken. Some months ago a provisional committee was formed in Hull which, after investigating the matter, decided that the formation of a society on the lines of the West Riding Medical Charitable Society was most desirable, and the views of the whole of the medical practitioners (nearly 500 in number) in the East and North Ridings and the city of York were obtained by circular letter. The response was so satisfactory that a meeting was held at York on May 21st and the society was definitely formed. More than 100 members have already joined, including a large number of life members. The annual subscription was fixed at 1 guinea and for life members at 10 guineas. Only members or their relatives can participate in the benefits. The first officers of the society are: President, Dr. J. Mitchell Wilson, Beverley. Vice-Presidents, Mr. W. H. Jalland, York; Dr. F. W. A. Godfrey, Scarborough; Mr. R. H. B. Nicholson, Hull; Dr. C. A. Lee, Hull; and Dr. H. J. C. Godfrey, Bridlington. Treasurer, Dr. E. M. Hainworth, Hull. Honorary secretary, Dr. Edward Tutton, Hull. From the support already received the future success of the society would seem to be assured.

THE FRANCO-BRITISH EXHIBITION AND SUNDAY OPENING.

THE question of the Sunday opening of this exhibition is now being much debated, and in this connexion it is interesting to quote the editorial article which appeared in THE LANCET of April 16th, 1853, referring to the opening of the Crystal Palace on Sunday, the Palace after it had been used for the Great Exhibition of 1851 having been removed to Sydenham:—

> Those who are industriously bent upon *resisting* the opening of the Crystal Palace at Sydenham on Sundays, seem to consider that their other arguments will be strengthened if they can enlist the support of the medical profession. A petition is now being *actively* circulated amongst medical practitioners, which appears to us to be singularly inconsistent in fact and reasoning. The document sets out with the following proposition:—
>
> > That your petitioners, from their acquaintance with the labouring classes and with the laws which *regulate the animal economy*, are convinced that a seventh day of rest, instituted by God, and co-eval with the existence of man, is essential to the bodily health and mental vigour of men in every station of life.
>
> We may freely admit the proposition; but how does it follow that escape from the dingy town, and "fresh air and recreation" in Penge Park must be "pregnant with disastrous results to the health of the labouring classes"? There may possibly be objections of a moral and religious character against the measure—and these it is not our province to consider—but certainly it is neither reconcileable with our knowledge "of the laws which regulate the animal economy," nor with the plainer laws of common sense, to contend for the closing of the Crystal Palace on Sundays on sanitary or medical grounds.

It will be seen that 55 years ago the same subject was being debated with as much vigour as it is this year, and it would not be surprising if the partisanship of the medical profession were attempted to be enlisted in the same manner that it was at that length of time ago. Medical men themselves who work seven days in the week should know a good deal about the effects of Sunday labour from a personal point of view, and it is possible that they may be represented as desirous of seeing the exhibition closed on Sundays in the interests of the persons employed in its management. On the other hand, it may be argued that the enormously increased receipts which would follow Sunday opening would enable the directors to enlarge their staffs and so to provide that their employees should get one day in seven free. The question of the opening on Sundays of the Franco-British Exhibition is obviously a difficult one, but we see little reason to contend for its closing on sanitary or medical grounds, even if the "fresh air" of Shepherd's Bush of 1908 be not quite comparable with the "fresh air" of Penge Park in 1853.

THE ILLINOIS STATE BOARD OF HEALTH AND ITS CRUSADE AGAINST TUBERCULOSIS.

WE have received copies of the seventh revised edition of a circular on "The Cause and Prevention of Consumption," issued by the Illinois State Board of Health and written by Dr. James A. Egan, secretary to the Board. This Board, with commendable public spirit, has started an active crusade against tuberculosis in the State of Illinois, and one of its chief objects is to diffuse knowledge among the general population in regard to the prophylaxis and treatment of this disease which, it is stated, causes 150,000 deaths annually in the United States and between 7000 and 8000 deaths in the State of Illinois. We learn from a cutting from the *Journal*, Springfield, Illinois, of Feb. 23rd that it is intended to distribute 100,000 copies of the circular to the physicians and school-teachers in the State, to University students, charitable organisations, clubs, churches, and other similar bodies. It is hoped that by the coöperation of the medical profession it will be possible to place a copy in the hands of every consumptive person in the State. Copies can be obtained without charge by any citizen in Illinois who desires to receive one. The circular itself is in the form of a pamphlet of 60 pages inclosed in a cover. It is liberally illustrated and is written in such a manner as to be easily intelligible to the layman, for whom it is, of course, primarily intended. After an introduction describing the prevalence of the disease and the ravages which it makes, the importance of prevention is pointed out and the phrase "No spit, no consumption" is repeated in thick type on many pages as a serious warning. General directions are given to consumptives as regards their mode of life, their diet, and their home treatment. Various illustrations are given of suggestions for open-air or "out-of-door" treatment at home, such as that by sleeping in a porch, verandah, or lean-to. The useful "window tent" introduced by Dr. S. A. Knopf of New York is also figured and described. Directions for the general hygiene of the sick room are given and excellent information is afforded in regard to disinfection. Nearly half the book is devoted to the treatment of consumption in Illinois and to a consideration of the need for a State hospital or sanatorium for the care of consumptives. Illustrations are given of some of the other sanatoriums in the United States, notably of the Adirondack Cottage Sanatorium at Saranac Lake. The Illinois State Board of Health is to be congratulated on the strenuous efforts which it is making to deal with this important problem and on the really admirable pamphlet which Dr. Egan has produced for it. If an abridged form of it could be supplied to many of the consumptives in this country it would serve a useful purpose.

HOSPITAL STOPPAGES IN THE NAVY.

THE *Naval and Military Record* in a recent issue directs attention to an ancient naval grievance, the existence of which is one of those mysteries that none but a Government office can attempt to explain. A man who contracts venereal disease is allowed 30 days' hospital treatment on full pay, but a man who, through no fault of his own, contracts other forms of disease is liable to certain reductions of pay whilst in hospital: after 30 days every naval patient is subject to these stoppages, irrespectively of the nature of his malady. The stoppages are slight but irksome, and the distinction drawn between the different classes of disease in their imposition is so unjust as to be almost ludicrous. The paper from which we quote remarks pertinently that sailors do not contract fevers purposely, or stop in hospital for the pleasure which they derive from it, but we cannot agree with its further dictum that every man who contracts venereal disease should have a portion of his pay stopped during the whole period of hospital treatment, for we hold that the disease brings sufficient punishment of itself. Moreover, the State secures the services of men under conditions which detach them from home influences and render marriage imprudent and in many cases impossible, whilst the temptations to which Jack ashore is exposed are notorious. The State at the same time, with what seems to many a pusillanimous dread of uninstructed public sentiment, enacts no preventive regulations to check venereal disease at any of the great naval stations. We would rather reserve the hospital stoppages for men who contract the disease and neglect to report it immediately they are aware of the fact to the medical officer of their ship or division, and who are detected subsequently, for such men injure themselves and the service and are, moreover, very liable to infect others.

THE HAMPSTEAD GENERAL HOSPITAL.

DURING the past year we have had on several occasions to refer to the affairs at the Hampstead General Hospital, which ultimately led up to its amalgamation with the North-West London Hospital. The constitution of the combined hospitals has been finally settled at a recent meeting of the council, at which it was decided that the regular out-patient department at present in existence at Hampstead should be closed and any necessitous cases should be referred in future to the department at Kentish Town. There is no shadow of doubt that an out-patient department is needed in that very poor district, and we think that the council has acted wisely in closing the department adjoining the hospital on Haverstock Hill except as regards the attendance of casualty cases. The existence of that department has been a standing grievance to many practitioners in the neighbourhood, and, at a time when the relations between the hospital authorities and the local medical men have been so unfortunately strained owing to a complexity of causes, the removal of a department which was very generally agreed to be unnecessary at Hampstead will, we hope, do something to smooth out the whole matter. With regard to the recent change of staff, we sympathise fully with the position of the gentlemen who have served the hospital so well and faithfully until the present rearrangement brought about their voluntary retirements, and we admire the manner in which they forfeited their personal interests in making common cause with their local professional brethren, but there is no doubt that the action of the hospital council was to a great extent forced by the fact that it has increased to such a size that it could not afford to become independent of King Edward's Hospital Fund, and this being the case the solution that has been arrived at was inevitable, hard as it was upon individuals. Now that the matter is *fait accompli* we can only express a hope that the utility of the institution will not be affected by anything of the nature of a professional boycott in the neighbourhood, for such a procedure could only harm the charity in question without in any way advancing the cause of those who desired the staff appointments to remain in the hands of local medical men.

LONDON INTER-COLLEGIATE SCHOLARSHIPS BOARD.

THIS Board was constituted in 1904, with the approval of the governing bodies of University College, King's College, and the East London College, for the purpose of holding a combined annual examination for entrance scholarships and exhibitions tenable at those colleges and at such other "schools" of the University of London as might afterwards agree to make use of the organisation of the Board. An arrangement has now been entered into with various other colleges and medical schools and a combined examination for medical entrance scholarships and exhibitions will be held in September next. The aggregate value of these scholarships and exhibitions amounts to £1500 and they are 23 in number. They are tenable in the faculties of medical sciences of University College, King's College, and in the medical schools of King's College Hospital, St. George's Hospital, Westminster Hospital, and the London School of Medicine for Women. The examinations will be held in London by the London Inter-Collegiate Scholarships Board on Sept. 22nd and following days. Candidates will be admitted to the examination for the scholarships and exhibitions under the various regulations governing them. For full particulars and entry forms application should be made to the secretary of the board (Mr. Alfred E. G. Attoe, University College, Gower-street, London, W.C.), or to the deans (or secretaries) of the medical schools concerned.

THE REFINING OF SALT.

IT may not be strictly a medical subject, but common salt is for domestic purposes so closely associated with our daily life, to say nothing of its importance in manufacture, that it may be of interest to refer to a great change, which has already got beyond the experimental stage, in the manner of its refining. No change in the principle of the refining process has taken place since before the time of the Romans —the solution of the rock-salt in water, with its subsequent evaporation. In the new process, called the Tee process after the name of the inventor, water is not used. The rock salt, impure and discoloured, as it is often found, is melted and purified by fire. While liquefied the impurities are precipitated and when the liquid cools and becomes solidified in a mould the salt is found at the top and the impurities below, while between the two is a distinct line of demarcation. A demonstration of the new process was given quite recently at some works near St. Helens. The rock salt was carried in barrows to the top of a huge oven and dropped in on to a metal plate heated to whiteness by gas. Rock salt requires for its melting a temperature of 1400° F., to which point the table evidently was heated, for it flowed off it as a liquid and fell into a recess below. After a time a quantity was drawn off into a large mould and compressed air was forced into it till a violent ebullition was set up to facilitate the precipitation of the impurities to the bottom of the mould. After the mould was allowed to cool it was found that all the mpurities had sunk to the bottom, leaving pure white solid alt at the top. The impure portion of the block is separated asily by a blow with a chisel. The pure salt may then e ground to any degree of fineness required. The new method is said to be much cheaper than the old one and much more economical of time, taking hours only while the ld one required days. Another advantage is that by the fire process the salt is freed from water and in this anhydrous condition is very slow in absorbing moisture from the atmosphere, so that no ingredients need be added to prevent t from "caking." Some hundreds of tons have been efined, tested, and analysed with, it is said, quite satisfactory results, and works on a large scale are to be erected where the new method can be carried on.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

It will be remembered that in Lord Mount-Stephen's letter o the Prince of Wales which accompanied his recent plendid donation to King Edward's Hospital Fund he expressed a hope that the friends of the fund would unite n raising the further capital sum required to increase the permanent income of the Fund to £75,000 a year, the income rom subscriptions being now estimated at the like sum. His Royal Highness has now contributed £500 himself and has received from Lord Revelstoke a gift of £500, from Mr. Frederick M. Fry £250, and from an anonymous donor £1000 as contributions to this object.

THE DALRYMPLE HOME FOR INEBRIATES: AN INTERESTING REPORT.

The annual report of the Dalrymple Home for 1907 shows a continuance of the steady progress which has marked the history of this institution under the management of its present medical superintendent, Mr. F. S. D. Hogg. During the year 36 patients were received and 39 were discharged. With regard to the patients received Mr. Hogg notes with regret that only ten were inebriates certified under the Act, the other 26 being private patients, over the duration of whose stay under treatment the physician can exercise no legal control. It is an extremely gratifying fact that, even under these very unfavourable conditions, the after-history of traceable cases should show so high a proportion as 62 per cent. under the rubric "doing well," while only 22 per cent. are returned as "not improved." It is interesting to note that Mr. Hogg's wide experience has satisfied him that the sudden and complete stoppage of alcohol is not attended by any of those risks to the health of habitual drunkards which many people, and, as Mr. Hogg drily observes, especially many patients, attribute to this drastic method. On the contrary, he has found that appetite and natural sleep are restored very much sooner when this mode of treatment is followed than when the use of alcohol is gradually discontinued. A matter on which Mr. Hogg lays very special stress and regarding which he speaks with exceptional authority, is the present unsatisfactory state of the law which so deplorably hampers the application of institutional treatment to drunkards who do not possess the further qualification of being criminals. As matters stand, a man may be in a condition of chronic alcoholic or drug poisoning or may be periodically in an unfit condition for decent society, but so long as he avoids criminal acts and is not persistently in such a state that he may be classed as insane, he is free to squander his capital, to ruin himself and his family, and to drink or to drug himself to death; and unless he decides to place himself under treatment nothing can be done to save him. The remedy which Mr. Hogg advocates is that inebriates of this class should be certified much in the same way as lunatics are certified and that they should be placed compulsorily under treatment before they have financially, mentally, and physically foundered. We find this simple plan reasonable; something of the sort should certainly be adopted when the Government fulfils its promise of introducing legislation to amend the Inebriates Acts.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN.

The following are particulars of the course of lectures and demonstrations which have been arranged to take place at the rooms of the Incorporated Society of Medical Officers of Health in London during Whit-week:—

Tuesday, June 9th.—3 P.M.: Opening Meeting in the rooms of the Society, 1, Upper Montague-street, Russell-square, London, W.C. Address by Dr. James Kerr, chief medical officer of the London County Council Education Department.

Wednesday, June 10th.—11 A.M.: Lecture on "Medical Inspection," by Dr. C. J. Thomas (L C.C. Education Department). 2 P.M.: Visit to schools. 5.30 P.M.: Lecture, "*Anthropometry,*" *Dr. F. C. Shrubsall*; *Physical Exercises*, Dr. Shrubsall.

Thursday, June 11th.—10.30 A.M.: Demonstration of Special Cases, Dr. Kerr (L.C.C. Education Offices). 11.30 A.M.: Office Routine; Ringworm Examination, &c., Dr. Thomas (L.C.C. Education Offices). Visits to Schools. 2.30 P.M.: Lecture, "Eyes and Ears," Dr. Kerr. 3.30 P.M.: Lecture, "School and Home; Infectious Diseases," Dr. H. Meredith Richards. 5.30 P.M.: Lecture, "School Clinics," Dr. A. H. Hogarth.

Friday, June 12th.—10.30 A.M.: Demonstration at London County Council Education Offices, Dr. Kerr. Visits to Schools. Further arrangements are in contemplation.

An exhibition of appliances, outfits, record systems, office requisites, and so on, will be open daily from 10 A.M. to 6 P.M. All desirous of attending the lectures are requested to communicate with Mr. W. A. Lawton, at the offices of the Incorporated Society of Medical Officers of Health, 1, Upper Montague-street, Russell-square, London, W.C.

THE SIXTEENTH INTERNATIONAL CONGRESS OF MEDICINE AT BUDAPEST, 1909.

A meeting of the National Committee for Great Britain and Ireland of the Sixteenth International Congress of Medicine was held at the rooms of the Medical Society of London on May 28th, Dr. F. W. Pavy, F.R.S., being in the chair. The National Committee was reconstituted by incorporating 22 new members with the former committee. It was proposed by Mr. W. H. H. Jessop, seconded by Mr. L. Eliot Creasy, and carried unanimously, that the officers of the new committee should be Dr. Pavy, President, and Mr. D'Arcy Power and Dr. Clive Riviere, honorary secretaries. Letters were read from the general secretary of the Congress stating that it would be held at Budapest from August 29th to Sept. 4th, 1909, under the patronage of his Imperial and Apostolic Royal Majesty Francis Joseph I. It was further reported that certain changes had been made in the method of obtaining scientific communications; no members or societies had been invited directly to contribute but all papers and discussions had been left to the initiative of individuals. In these circumstances the National Committee felt that it was necessary to urge those who proposed to read papers to send in the titles to the general secretary (Professor Emil Grósz, Esterhazy-utcza 7, Budapest VIII.) as soon as possible, because it is very desirable that the medical profession in the United Kingdom should be adequately represented at the Congress. The work of the Congress is divided into 21 sections of which the sixteenth section, Otology, is to be held simultaneously with the Eighth International Congress of Otology. The remaining sections are Anatomy and Embryology, Physiology, General and Experimental Pathology, Microbiology (Bacteriology) and Pathological Anatomy, Therapeutics, which includes Pharmacology, Physical Therapeutics and Balneology, Internal Medicine, Surgery, Obstetrics and Gynæcology, Ophthalmology, Diseases of Children, Diseases of the Nervous System, Psychiatrics, Dermatology and Venereal Diseases, Diseases of the Urinary Tract, Laryngology, Otology, Stomatology, Hygiene and Prophylactic Medicine, Medical Jurisprudence, Military and Naval Hygiene, and Tropical Diseases. There will probably be the usual reduction in railway fares for those who attend the Congress but no details are as yet forthcoming. Should a sufficient number of members from Great Britain and Ireland signify their intention of attending it may be possible to obtain a special through train from Boulogne to Budapest. The cost of membership is 25 crowns (which is approximately £1 sterling) for each member and half that amount for members' wives and daughters. The money can be remitted by post-office money order payable to Professor Dr. Elischer, treasurer of the Congress, at the current rate of exchange.

THE death is announced of Dr. Prior Purvis of Blackheath at the great age of 95 years. Dr. Purvis obtained the degree of M.D. London in 1842.

THE President of the Board of Education has appointed Miss Janet M. Campbell, M.D. Lond., to the Medical Department of the Board.

THE annual banquet of the Coroners' Society of England and Wales will be held at the Holborn Restaurant, London, on Thursday, June 18th, at 6.45 for 7 P.M. The honorary secretary is Mr. Walter Schröder.

THE Hunterian Society has decided to award a silver medal annually for the best essay by a general practitioner embodying the results of original observations. Intending candidates can obtain full particulars from the senior honorary secretary, Dr. W. Langdon Brown, 37A, Finsbury-square, London, E.C.

THE annual Bolingbroke lecture will be delivered on Friday, June 12th, at 9 P.M., before the South-West London Medical Society, at the headquarters of the 4th Volunteer Battalion East Surrey Regiment (opposite Clapham Junction Station), by Dr. David Ferrier who has taken as his subject "Hysterical Paralysis." Medical men other than members of the society are cordially invited.

THE Harben lectures (1908) of the Royal Institute of Public Health will be delivered in the lecture theatre of the institute on Wednesday, June 10th, 17th, and 24th, at 5 P.M., by Professor George H. F. Nuttall, M.D., D.Sc., F.R.S., Quick Professor of Biology in the University of Cambridge, on the following subjects:—Lecture 1, Ticks, their Biology and Structure; Lecture 2, Spirochætosis in Man and Animals; and Lecture 3, Piroplasmosis. To these lectures all who may be interested are cordially invited.

EASTBOURNE WORKHOUSE.—It is not at all surprising to learn that the Local Government Board will not permit of any further extension of the old workhouse premises at Eastbourne. The guardians had hoped to provide for their increasing indoor poor in this way but met with a prompt refusal. The present buildings, originally cavalry barracks, were all very well when workhouses were chiefly for the relief of the able-bodied and not the sick, the aged, and the infirm, who now greatly preponderate, and in view of the great changes that have come over Poor-law administration, particularly as regards the nursing of the sick, it seems a wonder that the guardians were not called upon to build new premises some years ago. The board has now decided to build a new workhouse on its estate at Willingdon to accommodate 550 inmates at a cost of £50 per bed for the able-bodied, and £100 per bed for the infirmary inmates. This decision was only arrived at by a very narrow majority, several guardians favouring delay until the report of the Poor-law Commission was issued. Of the present inmates 102 [illegible] age of 70 years.

AMERICA'S TRIUMPH IN PANAMA:

THREE YEARS' MEDICAL AND SANITARY RECORD IN THE CANAL ZONE.

BY JOHN GEORGE LEIGH.

IT was my privilege some three years ago to contribute to the pages of THE LANCET a series of articles[1] explanatory of certain climatic and hygienic problems then facing the United States Administration in the inaugural stages of the stupendous enterprise which it had undertaken and pledged itself to achieve in the Central American isthmus. In these I expressed a firm conviction that, despite some initial errors (not, I trust, unkindly criticised), and many visible and yet undisclosed difficulties, success would crown its efforts; basing my confidence—not upon the feasibility of the project, the skill of modern engineers, or the command of immense monetary resources—but upon the probability of a satisfactory reply being forthcoming to the following question: Can the health conditions of the isthmus be so ameliorated as to prevent, during the period of canal construction, a recurrence of the appalling mortality among the labourers which accompanied the building of the Panama railroad and the work of excavation along the canal route in the days of the de Lesseps Company? In the course of my remarks I referred at considerable length to the eventful and usually lugubrious history of the isthmus; the latter's evil reputation as a hotbed of malaria and yellow fever; and the misgivings with which sincere well-wishers of the enterprise regarded a then threatened radical modification in the design of the canal. Superficially, it seemed a matter of little moment, from the standpoint of health conditions, whether the canal were built with a summit level and locks or excavated throughout the entire distance to 35 or 40 feet below the mean level of the ocean. It is happily unnecessary to-day to recall the arguments with which I sought to controvert this assumption and to demonstrate, on the contrary, that the question was of paramount importance; for the sea-level canal—thanks to the strenuous opposition of the few rather than the good sense of the many—has gone the way of the Nicaragua, Darien, and other more or equally specious projects for uniting by an artificial navigable highway the waters of the Atlantic and Pacific oceans.

It may, however, be pointed out that the fear expressed in June, 1905, was amply justified, for early in the following year a majority (including all the foreign members) of the Board of Consulting Engineers, to whom had been delegated consideration of all the plans, decided to recommend, for final adoption by President Roosevelt and Congress, a waterway everywhere brought down to sea-level. This result was hailed with satisfaction from two quarters: by the men who honestly believed that such a canal, when completed, would offer superior advantages to commerce, and by others interested in the trans-continental railroads, who remained faithful to the tradition of supporting that rival enterprise which promised to be most difficult and dangerous and costly in time and money. Their joy, however, was but short-lived, for, side by side with the recommendation to which I have referred, the President and Secretary of War were able to consider reports from the minority of the Consulting Board and the then Isthmian Canal Commission and chief engineer, each strongly favouring adherence to the high-level project as not only more desirable from technical and economic standpoints but also as promising superior efficiency. The arguments advanced in these documents seemed, and indeed were, so conclusive that Congress, after some months of useless talk, abandoned its earlier and newly revived predilections and decided to vote the required appropriations, leaving to the President, his advisers, and nominees unfettered discretion in determining and building such type of canal as appeared to them desirable.

In my first article, referring to the impending conflict, I wrote: "It seems not unreasonable to suggest that, before the fateful decision, the last word should be spoken not by the aspiring engineer but by the profession which will be held mainly responsible should the prophecies of ill be justified by events." Fitting regard was, of course, given by the Executive and Congress to engineering and commercial considerations, but no one will deny that both in committee and open debate the really determining arguments were those having relation to topography, climate, and hygiene. It was, in brief, impossible to avoid the conclusions that the more disturbance there was of the low-lying, malaria-laden marsh lands, and the longer the time devoted to the work of canal construction, the greater must be the risk of abnormal sickness and mortality among the labourers and their supervisors, and this quite regardless of the measure of success, large or small, attending the operations of the medical and sanitary departments.

---

[1] Sanitation and the Panama Canal: the Solution of Certain Climatic and Hygienic Problems, THE LANCET, June 3rd (p. 1530), 10th (p. 1597), and 24th (1726), 1905.

Since the sea-level project was dismissed from consideration as a practical alternative to the proposed canal with locks the isthmus has been the theatre of remarkable activity and continued valuable work. Appreciation of the last-mentioned was, however, for a long time overshadowed by bickerings and discord among the many administrative departments, the intrigues of politicians at Washington, and the persistence with which sensation-mongers, not always of the usual irresponsible type, devoted themselves to the apparently congenial occupation of "smelling out" scandals and threatening lurid "revelations." Among those who took part in this campaign were, it is regrettable to recall, some members of the medical profession, whose allegations for the most part were based upon the distorted and unsubstantiated testimony of dismissed or disgruntled employees or, at the best, a few days', ofttimes few hours', personal experience of the isthmus. The situation at length became so unendurable, and even dangerous, that it was with positive relief that well-wishers of the enterprise received the announcement of the revolutionary administrative changes of March and April of last year.

These changes placed the government of the Canal Zone and the work of canal construction, actually as they had already been in theory, in the hands of the War Department and freed both from the incubus of political interference. All the members of the then existing and newly reconstituted Canal Commission were induced to resign and to the vacancies thus created were assigned Lieutenant-Colonel G. W. Goethals of the Corps of Engineers, U.S.A., as chairman and chief engineer; two officers of the same corps, Major D. D. Gaillard and Major W. L. Sibert; Colonel W. C. Gorgas, M.D., Assistant-Surgeon-General, U.S.A.; Civil Engineer H. H. Rousseau, U.S.N.; and two civilians, Mr. J. C. S. Blackburn and Mr. Jackson Smith. All these appointments have been fraught with happy consequences, and none more so than that of Colonel Gorgas, whose promotion to the rank of Commissioner must be regarded not only as a well-merited personal compliment but also as a national recognition through the chief of the Executive of the immense services which are being rendered to the United States in the prosecution of its great undertaking by members of the medical profession. It has been largely due to the devotion with which his staff has seconded Colonel Gorgas's efforts and to the loyal support given by the Administration to the policy and representations of the health officers that it is already possible to describe the canal enterprise as realising the writer's confident belief of 1905—namely, that it would, "during construction, prove the most striking object-lesson ever offered of the benefits to be derived from a well-organised sanitary organisation associated with a great public work."

Before I review the achievements on which this assertion is based it may be desirable to refer, in brief and general terms, to the character of the undertaking as a whole. The canal now in course of construction differs in many essential details from that outlined by me in 1905 and that recommended for adoption in the reports of engineering experts to which reference has already been made. During the past two years and even within the last few months the plans have been subjected to such drastic revision and modifications that, until now, it has not been possible to estimate, with any measure of certainty, their complete scope and approximate cost. As now arranged, the Atlantic terminal of the canal will be between breakwaters built across the entrance of Limon Bay, and thence ships will pass through a channel, 500 feet wide and 41 feet deep to the shore line, a distance of 4·55 miles, and to the locks at Gatun 2·6 miles inland. At Gatun there will be built duplicate flights of three locks, by which the summit level will be reached, and also a great dam and regulating works. The object of these latter is to form a great reservoir, or inland lake, some 170 square miles in area, giving open navigation in a broad waterway all the way from Gatun to Obispo, and into which the floods of the Chagres will be received, controlled and utilised for the service of the canal. The total length of the lake—the surface of which will be 85 feet above the mean level of the oceans—will be 30 miles, and for half this distance only a small amount of excavation will be required to provide a navigable channel 1000 feet wide at the bottom and 45 feet deep. Elsewhere, as the amount of excavation necessary to obtain the minimum depth of 45 feet increases, the width will be decreased to 800 feet for a distance of 3·86 miles, 500 feet for 3·73 miles, 300 feet for 1·55 miles, and, finally, to 200 feet for 4·7 miles through the deepest portion of the Culebra cutting. Then the channel will become 300 feet wide for 1·88 miles to the Pedro Miguel lock, where the summit level will end, and the first descent be made to the level of the Pacific. This will be finally reached by a flight of two locks at Miraflores, whence there will be a channel, eight miles in length and 500 feet wide, to deep water in the ocean. Thus the total length of the canal from ocean to ocean will be 49·72 miles, divided into four levels by three flights of six locks, the last being in duplicate in order to provide against any delay to shipping arising out of the from time to time inevitably necessary repairs and renewals.

From data gathered and surveys made during the first year or so of the American occupation of the Canal Zone it has been estimated that to complete a navigable highway between the oceans of the type outlined above there would be required 124,310,000 cubic yards of excavation. Of this quantity—the immensity of which may be gauged from the fact that one and a half cubic yards of rock or earth is a good load for a two-horse waggon—the American steam-shovels and dredges accounted for 9,795,000 cubic yards up to March 30th, 1907. So nearly perfect, however, was the organisation on that date that in the 12 months following there was added to the record of excavation no less than 22,000,000 cubic yards, of which quantity about half was removed from the Culebra cutting. The record of monthly excavation has also regularly been raised. The totals, for example, for August, September, and October last, the three wettest months of the year, were respectively 1,285,791, 1,517,412, and 1,868,729 cubic yards, as against for all three corresponding months of 1906 1,470,779 cubic yards. In February, 1908, the total excavation was 2,945,880 cubic yards, and in the following month no less than 3,480,270 cubic yards. Added significance is lent to these figures by the fact that under the old *régime* 1,000,000 cubic yards a month was looked upon as a record only to be reached under the most favourable conditions.

The performances of the Department of Excavation and Dredging during the year ended March 30th last are not only remarkable in themselves but also eminently suggestive of the near approach of the time when we may begin to talk confidently of the completion of the canal. If work could be continued at the same high pressure and "making the dirt fly" were the only or main consideration, five years hence might witness the solution of the great problem which has vexed civilised mankind since Balbao first gazed upon the Pacific. To complete the Panama Canal, however, there will be required huge locks and dams and other accessory structures, some of dimensions and types unparalleled in the history of modern engineering, and one at least of such daring character as to be vindicated only by success. Preparations are now on foot for the initial work of construction, and it is hoped that the latter may be continued *pari passu* with the removal of earth and rock so as to justify the apparently not over-sanguine expectation of the authorities on the isthmus that the canal will be practically completed, if not actually opened for traffic, in the early months of 1915.

When the Americans, on May 4th, 1904, took formal possession of the canal properties they found between 600 and 700 men employed on the works, the majority continuing in somewhat perfunctory fashion the excavation of the Culebra cutting and the remainder occupied as caretakers of the machinery and stores of the French company. In the following November the Canal Commission's employees on the isthmus numbered 3500; on June 30th, 1906, there were on the canal work 500 white Americans and Europeans and 13,625 West Indians, and on the Panama Railroad an additional force of 5475 men; on June 30th, 1907, the canal employees numbered 4317 whites and 14,606 West Indians and those of the railroad company 10,523; and at the end of January last the total force of the Canal Commission actually at work was 25,367 men and of the Panama Railroad 6557 men. On Feb. 29th last the white employees of the Commission numbered 5083 and of the Panama Railroad 1091, all accommodated, together with 1275 women and 1067 children, in quarters provided by the Commission. There were also on the same date about 200 women and 200 children, relatives of white employees, residing in independent quarters in Colon and Panama.

Referring in June, 1905, to the health conditions then prevailing in the isthmus—improved certainly since the American occupation, but still far from satisfactory—I deprecated very strongly, first, any undue haste in introducing the vast army of immigrant labour required to complete the canal; and, secondly, the inclusion among these recruits of any considerable number of Asiatics (Chinese or Japanese), "the most susceptible of any people to yellow fever infection. It must now be evident," I added, "even to the most confirmed doubter, that yellow fever is still endemic on the isthmus, and that neither Colon nor Panama can be considered reasonably secure from a recurrence of dangerous outbreaks until each is provided with an ample and wholesome water-supply; for, pending such improvement, it is obviously impossible to prohibit the use of water-containers, the favourite breeding place of the stegomyia mosquito. Nor can it be hoped, until the long-promised waterworks and sewers are in operation, that there will be any sensible diminution in the general death-rate."

For purposes of comparison (always bearing in mind for later periods the increased population, largely of immigrant labour, with but little earlier experience of sanitary regulations) between the condition of things during the first months of American rule and figures to be hereafter quoted the following brief summary of statistics will repay attention. The death-rate per 1000 among the entire population of the Canal Zone, Panama, and Colon, during the year ended Oct. 31st, 1905, was 53·78, the records ranging from about 40 in the earlier months to 66·40 in October. During the same period the rate of mortality among employees of the Canal Commission averaged 24·30 per 1000, the minimum return of any one month being 14 and the maximum, that for July, 46·11. The total record of cases of yellow fever and deaths from July 1st, 1904, to Oct. 31st, 1905, was 241 and 80 respectively, the maximum figures of 62 cases and 19 deaths being those of June. Other deaths by disease throughout the zone during the 15 months ended August 31st, 1905, were: malarial fever, 86; typhoid fever, 10; pernicious fever, 22; dysentery, 46; beri-beri, 36: tuberculosis of the lungs, 54; and pneumonia, 49.

Since the period with which these figures deal the isthmus has been the scene of many remarkable changes; indeed, it may without exaggeration be said that not only the face but also the character of the country have been altered. In my earlier contributions, it may be remembered, I referred at length to the physiological effects of its high temperature and debilitating humidity, accentuated by the noisome exhalations from decomposing organic matter, upon not only people accustomed to a temperate climate but also upon the native population. It seemed then almost ridiculous to anticipate that these effects could be sensibly modified, that life in the zone could be made endurable for the foreigner, or that the native could be awakened from his traditional sloth and disregard of the first elements of the laws of hygiene. Yet in three short years all this has happened. Panama and Colon, from hot-beds of disease have been transformed into practically new cities, not only by the provision of complete waterworks and sewerage systems, an efficient system of quarantine, the reconstruction or widening of many thoroughfares, and the paving of every street with stone or brick, but also by the now willing coöperation of their people in furthering the designs of the masterful American. The older hospitals have been enlarged and modernised, and wherever required new ones have been erected and properly equipped. At every important point along the canal line water and sewer systems have been installed, and nothing has been left undone to impress both native and immigrant employee with a sense of the dominant Power's appreciation of the value of life and health. The arrangements for the housing and feeding of the army of workers, white and coloured, on the canal and railroad leave little to be desired, and—a matter too often neglected in enterprises involving the employment of a large labour force—every possible encouragement is given by the Commission to the promotion of healthy social life.

The first result of all this care to which attention should be directed is the fact that for two years there has been no case of yellow fever on the isthmus, the last case having occurred in Colon in May, 1906. Yet yellow fever continues to be present in all the countries around the zone with which the latter has commercial relations. Bubonic plague is also prevalent on the Pacific coast, both north and south of the isthmus, but no case has occurred in the zone since 1905. Here we have abundant proof of the virtues of quarantine and a fairly substantial assurance that, thanks to pure water and to the vigilance of the sanitary corps, yellow fever has been practically stamped out in Panama and Colon. Even more interesting, however, is the record in respect of malaria. Of the deaths in 1907 among the workers on the canal line only 4·57 per 1000 can be attributed to diseases ordinarily known as tropical, among which, of course, is included malaria in its various forms. There were admitted to the hospitals last year, when the labour force averaged over 39,000, 16,753 cases of malaria, as compared with 21,739 cases in 1906, when the average force was but 26,000, indicating that in one year malaria had been reduced just 50 per cent. It is also worthy of note, as showing a greatly increased resisting power among the blacks, that whereas in 1906 the death-rate from malaria was approximately among the whites 2 per 1000 and among the blacks 8 per 1000, the same rates in 1907 were respectively 3 and 4 per 1000.

Other interesting data, all evidencing improved health conditions, resulting from more perfect sanitary and hygienic organisation, will be found in the following table:—

	1907.	1906.
Average number of employees of all grades (Canal Commission and Panama Railroad)	39,343	—
Deaths	1,132	—
Annual death-rate per 1000	28·77	41·24
Average number of white employees	10,709	—
Deaths	179	—
Annual death-rate per 1000	16·71	16·27
Average number of American white employee	4,300	—
Deaths	42	—
Annual death-rate per 1000	9·76	—
Deaths from disease	29	—
Death-rate from disease per 1000	6·74	—
Average number of negro employees	28,634	—
Deaths	953	—
Annual death-rate per 1000	33·28	49·01
Women and children in Commission quarters	1,367	—
Deaths	9	—
Death-rate per 1000	6·73	—
Average number of sick employees per day	987	—
Rate per 1000	25	—
Deaths from dysentery	48	69
Deaths from malaria	154	233
Deaths from pneumonia	328	421
General population of the Canal Zone, including Panama and Colon	102,000	66,000
Annual death-rate per 1000	33·63	49·1
Deaths from malaria	568	712
Deaths from dysentery	116	190
Deaths from pneumonia	681	720
Deaths from beri-beri	53	68

The records of the first three months of the current year are even more satisfactory and indicate a marked improvement as compared with the corresponding periods of 1907. Indeed, they provide the most favourable reports which the Health Department has been able to make. The death-rates for the whole population of the Canal Zone are especially noteworthy and compare favourably with those of many European and American cities, while the statistics having relation to the canal and railroad labour force indicate that the mortality among the latter is less than one-third what it was two years ago.

Referring particularly to the figures for March, it will be seen that the death-rate among employees was only about one-fourth what it was a year ago, the improvement (10·80, against 48·50 per 1000) being especially marked in the case of the negro workers. Taking special diseases and comparing the same months, the statistics are no less satisfactory. For example, in March of this year the deaths from malarial fever were nine, from pneumonia five, from tuberculosis three, and from typhoid fever one, as against, in March, 1907, 16, 53, 12, and nine respectively. This year there were admitted to the hospitals among the employees 533 malaria cases as against 1576, and the general sick-rate fell from 22·97 to 18·23 per 1000. It is also noteworthy that, although the weather conditions this year have been abnormally favourable to the development of

Anopheles the average weekly malarial sick-rate in the Canal Zone has been less than one-third of that during the three months ended March 31st, 1907. Records show that there is usually less malaria in May than in any other month of the year, yet the malarial rate for March last was about one-half that of the preceding May.

When Colonel Gorgas in 1904 entered upon his duties as head of the Health Department he fully recognised the importance and difficulties of the task set before him. Yet at the same time he quite frankly acknowledged that the political conditions ruling in the Canal Zone and the quite exceptional powers secured to the United States authorities for putting into force far-reaching sanitary rules and regulations could not fail to be most valuable auxiliaries to himself and his medical coadjutors. Among the latter, also, he found many men who, like himself, had had large experience of tropical people, diseases, and sanitation; and he well knew that, whatever efforts might be made to thwart his endeavours or impugn his methods, there would be no inclination on the part of those highest in authority to dispute his judgment. Reviewing these advantages, he very candidly confessed that the service of which he was the head "ought to be able to get up a model sanitary department." He set out to create this and, if success be measured by results, has most assuredly achieved his purpose.

Therefore, while claiming for the medical and sanitary staffs on the isthmus a maximum measure of credit for cleansing the country and thereby maintaining in the highest state of efficiency the army of canal and railroad workers, I regard it as a bare act of justice to record my conviction that without loyal support from headquarters much of the success would have been impossible. President Roosevelt has, at every stage of the enterprise, reiterated the sentiments expressed in his letter to the Secretary of War on May 9th, 1904, and Mr. Taft, as administrative head of the canal, has never faltered in his allegiance to them. As recently as Jan. 16th last Mr. Taft attended a meeting of the Senate Committee on Inter-Oceanic Canals, and in reply to some heckling on the subject of the cost of sanitation declared that the Government had in this matter adopted and followed a fixed policy—that of acting on the advice of the Isthmian medical staff. "The Government did not care," he said, "to assume the responsibility of acting contrary to the views of the doctors." "Moreover," he added, "Dr. Gorgas has proved so uniformly successful that we have felt fully justified in taking his advice in such matters. ...... The Spanish war has taught us and all the world how to live in the tropics."

In the lap of the gods rests the future of the Panama Canal enterprise. Whether it prove the great engineering triumph and commercial highway to which many of us look forward with confidence time alone will show; but of one credit history can never rob the United States. Among much good and evil it must record that it was under American administration that the knowledge and resources of modern science were applied to the hygienic redemption of the once noisome isthmus. Such fruits of labour in this direction have already been gathered that they promise to rival as a worthy monument of American achievement even the canal itself.

THE DIFFICULTIES UNDER THE MIDWIVES ACT.

If the full benefit is to be derived from the Midwives Act when it comes into plenary force in 1910 the various associations for the supply of midwifery nurses will have to be prepared with some definite scheme to place before the Privy Council and the Local Government Board, the two authorities which are responsible for carrying out the provisions of the Act. Until a scheme satisfactory to all concerned is definitely adopted it cannot be expected that either the Government or the public will do much towards supplying the funds which will be needed. Real efforts are being made to overcome the difficulties which hitherto have threatened to stand in the way of carrying out the full powers which the Act admits, and it is possible that coöperation between the different workers may result in some satisfactory proposals.

At a meeting of the Cottage Benefit Nursing Association held at Denison House, Vauxhall Bridge-road, London, on May 20th, under the presidency of Lord Ancaster, Mrs. Charles Hobhouse, referring to what was likely to take place when the Midwives Act came into full force in 1910, said she thought it was important that all voluntary associations should unite and ask the Government for one particular line of policy. With this object it was proposed to hold in July a meeting in London of the different associations throughout the country. Miss B. M. Broadwood, honorary secretary and director of the Cottage Benefit Nursing Association, said that in starting the association she was advised of the undesirability of introducing certificated midwives into the country who might be tempted to take the place of medical men. On the other hand, it was clear that there were large districts where medical men made no attempt to practise midwifery among the very poor. In such districts there could be no objection to midwives being employed. She suggested that branches of the Cottage Benefit Nursing Association should adopt the distinct rule that a midwife should only be supplied to a labourer earning not more than 15*s.* a week and that a charge of 15*s.* 6*d.* should be made to include two weeks of service after the child was born. The service of a medical man should be retained in every case at a fee of 5*s.* 6*d.* prepaid by a branch of the association. If it were necessary that the medical man should be called in by the midwife a further fee of 15*s.* 6*d.* should be paid. She added that there was a great danger in turning loose upon the community women with the qualification of midwife who were not absolutely going to practise in some definite post. She thought that it would be useful if medical men would send their opinions on these subjects to the office of the Cottage Benefit Nursing Association.

Another sign of the prevailing desire that the provisions of the Act shall be utilised to the fullest advantage is a letter which has been sent to the chairmen and clerks of county councils signed by Lord Goschen, chairman of council, Queen Victoria's Jubilee Institute of Nurses, 120, Victoria-street, London, S.W.; Mrs. Agnes Mabel Bruce, chairman of executive committee, Association for Promoting the Training and Supply of Midwives, Dacre House, Dean

Farrar-street, London, S.W.; Mrs. Josephine Heywood Johnstone, chairman of executive committee, Rural Midwives' Association, 47, Victoria-street, London, S.W.; Miss Alice Gregory, honorary secretary of the Home for Mothers and Babies, Wood-street, Woolwich; and Miss J. Wilson, president of the Midwives' Institute, 12, Buckingham-street, London, W.C. As will be seen by the document which follows the representatives of the different bodies unite in thinking that a local rate is the obvious way in which the expenses of providing midwives in accordance with the Act can be met:—

> We are aware that in many parts of the country grants are made for training local women, and that admirable voluntary organisations are at work; but so far no official or concerted action has been taken to insure that midwives will be within the reach of mothers in remote and sparsely populated districts where no voluntary organisation exists, where the number of births cannot afford a maintenance to a midwife, and which suffer from the further disadvantage of being far from medical aid. There is no doubt from information in our possession that in many areas the year 1910 will bring great difficulty unless prompt action is taken. In view of the vital importance of midwives to the greater number of mothers of the working class, and of the responsibility, as local supervising authority, already placed by the Act upon county councils, we venture to ask whether steps could be taken to obtain Parliamentary power to incur expenditure, when necessary, to insure a due provision of midwives in each county in coöperation with, or supplementary to, existing nursing and other associations. In making this suggestion we are fully aware (1) of the danger of pauperising the poorer classes by the provision of assistance for which they ought to be responsible; (2) that there exists already a very large amount of voluntary effort and organisation which should be encouraged to the utmost. The fact remains, however, that such organisation is by no means universal; and many rural districts are and will be entirely unprovided with trained women unless there is a central body in each county with power to act in case of necessity. As the local authority appointed by the Act, we respectfully, therefore, urge upon your council the consideration of the questions we have raised, and of whether such expenditure should fall upon the local rate, or be in the form of an Exchequer grant, made on need shown by the council for such assistance. Such a grant could be applied for annually as occasion might demand, seeing that the necessity would, in many instances, be temporary, pending, for example, the working up of a practice of a midwife, or by the formation of a voluntary local organisation. We would point out that in many European countries this difficulty of remote districts is met very frequently by the payment to the midwife of a minimum wage by the State or by local authorities.

The letter does not take into account the difficulty caused by the midwife being obliged to call in medical men in certain circumstances, while there is no provision for the payment of medical fees. It seems to us that a conference of all interested in the subject would find excellent material for debate.

INTERNATIONAL CONGRESS ON TUBERCULOSIS AT WASHINGTON.

SEPT. 21ST TO OCT. 12TH, 1908.

WE have received the following complete list of the executive committee for Great Britain and Ireland in connexion with the Washington meeting:—Chairman: Sir William Selby Church, Bart., K.C.B., ex-President of the Royal College of Physicians of London. Vice-Chairman: William Osler, M.D., F.R.S., Regius professor of medicine in the University of Oxford. Honorary Treasurer: Theodore Dyke Acland, M.D., F.R.C.P., physician to St. Thomas's Hospital, consulting physician to Brompton Hospital for Consumption. England:—Sir Thomas Clifford Allbutt, K.C.B., Regius professor of physic in the University of Cambridge; German Sims Woodhead, M.D., F.R.S. Edin., professor of pathology in the University of Cambridge; Sir Felix Semon, K.C.V.O., M.D., F.R.C.P., physician extraordinary to His Majesty the King; H. Timbrell Bulstrode, M.D., medical inspector to the Local Government Board; W. Watson Cheyne, C.B., F.R.C.S., F.R.S., professor of clinical surgery, King's College; J. Kingston Fowler, M.D., F.R.C.P., visiting physician to King Edward VII. Sanatorium, consulting physician to Brompton Hospital for Consumption; Charles H. Garland, chairman of the National Association for the Provision of Sanatoria for Workers suffering from Tuberculosis; G. A. Heron, M.D., F.R.C.P., senior physician to the City of London Hospital for Diseases of the Chest; James Kerr, M.D., medical officer Education Office, London County Council; Percy Kidd, M.D., F.R.C.P., visiting physician to King Edward VII. Sanatorium, consulting physician to Brompton Hospital for Consumption; Arthur Latham, M.D., F.R.C.P., physician to St. George's Hospital, senior assistant physician to Brompton Hospital for Consumption; Arthur Newsholme, M.D., F.R.C.P., chief medical officer to the Local Government Board; Joseph John Perkins, M.B., F.R.C.P., physician to Brompton Hospital for Consumption, physician to outpatients, St. Thomas's Hospital (*honorary secretary*); J. Edward Squire, C.B., M.D., senior physician to Mount Vernon Hospital for Consumption; A. William West, chairman of St. George's Hospital; C. Theodore Williams, M.V.O., M.D., F.R.C.P., visiting physician to King Edward VII. Sanatorium, consulting physician to Brompton Hospital; Sir Isambard Owen, M.D., F.R.C.P., Vice-Chancellor of the University of Wales, Principal of Armstrong College; Sheridan Delépine, M.B., professor of pathology and bacteriology of Victoria University; I. Walker Hall, M.D., professor of pathology, University College, Bristol; E. W. Hope, M.D., medical officer of health of the city and port of Liverpool; Nathan Raw, M.D., F.R.C.S., F.R.S. Edin., member of the International Committee for the Prevention of Consumption; John Robertson, M.D., medical officer of health of the city of Birmingham; and John C. Thresh, M.D., medical officer of health to the Essex County Council. Wales:—William Williams, M.D., medical officer of health of the county of Glamorgan. Scotland:—The Rt. Hon. Sir Herbert Maxwell, Bart., F.R.S., chairman of council of the National Association for the Prevention of Consumption; Matthew Hay, M.D., medical officer of health of the burgh of Aberdeen, professor of forensic medicine and public health in the University of Aberdeen; J. Patten MacDougall, C.B., Vice-President of the Local Government Board for Scotland; Leslie Mackenzie, M.D., medical member of the Local Government Board for Scotland; D. J. Mackintosh, M.V.O., M.B., C.M., F.R.S. Edin., medical superintendent of the Western Infirmary, Glasgow; R. W. Philip, M.D., F.R.C.P., F.R.S. Edin., physician to the Royal Infirmary and Royal Victoria Hospital for Consumption, Edinburgh; Ralph Stockman, M.D., F.R.S. Edin., professor of materia medica and therapeutics in the University of Glasgow; and Charles Templeman, M.D., medical officer of health of Dundee. Ireland:—Her Excellency the Countess of Aberdeen (President); Sir John Byers, M.D., professor of midwifery, Queen's College, Belfast; Sir Robert Matheson, LL.D., Registrar-General for Ireland; Sir John William Moore, M.D., F.R.C.P.I., professor of medicine at the Royal College of Surgeons in Ireland; Sir William J. Thompson, M.D., F.R.C.P.I., physician in ordinary to the Lord Lieutenant of Ireland; A. E. Boyd, M.B., D.P.H., honorary secretary of the Dublin branch of the National Association for the Prevention of Consumption; A. E. Mettam, B.Sc., M.R.C.V.S., M.R.I.A., Principal of the Royal Veterinary College of Ireland; E. J. McWeeney, M.D., D.P.H., bacteriologist to the Local Government Board for Ireland, professor of pathology and bacteriology to the Catholic University, Dublin; T. J. Stafford, C.B., F.R.C.S.I., medical commissioner to the Local Government Board for Ireland; and P. J. O'Sullivan, M.D., professor of medical jurisprudence, Queen's College, Cork.

Our own country will also be officially represented in accordance with the invitation of the United States Government, and delegates and representatives will attend in large numbers from most, if not all, civilised countries. It is especially to be desired that Great Britain and Ireland should be worthily represented, partly because the Congress is being held in a country so near akin to our own and partly because of the foremost position among the great nations which we have always taken in sanitary advance and the diminution of tuberculosis. In addition to sending representatives it is hoped, therefore, that the various public bodies will contribute descriptive and statistical accounts (including charts, models, &c.) of their work in dealing with tuberculosis. In this connexion it should be added that the Congress will include a museum, in which such charts, models, &c., will find a place. Dr. J. J. Perkins, honorary secretary of the executive committee for Great Britain and Ireland, will be pleased to give further information to all who desire it.

The members of the Congress are of two classes: Active members, who pay a fee of 5 dollars and who receive, besides the ordinary privileges of membership, the full set of published transactions without extra charge; and associate members, who pay a fee of 2 dollars. Associate members do not receive the published transactions or vote in the Congress, but they receive the official badge, the printed matter distributed during the Congress and at the exhibition, and share in the entertainments, attend the meetings, clinics, demonstrations, &c., and have the benefit of special transportation and hotel rates. An itinerary of special excursions for members is being prepared.

The subscriptions should be forwarded, payable to Mr.

Henry Phipps, treasurer of the International Congress on Tuberculosis, to Dr. John S. Fulton, secretary-general, 714, Colorado Building, Washington, D.C., U.S.A.

MEDICINE AND THE LAW.

The Problem of Expert Testimony.

AT a meeting of medical men in Boston, U.S.A., recently the following motion was carried :—

> That this committee recommend to the various district societies of the State a plan by which physicians, when called to make examinations for the purpose of testifying in court, shall make that examination upon the basis of a professional consultation.

Such a plan has been adopted by Dr. F. W. Anthony of Massachusetts for several years with great success; it has, in practice, been approved both by bench and by bar. Those who favour original legislation to deal with the abuses of expert evidence allege, however, that one cannot deal with "shysters" upon this footing, or, possibly, it may be urged upon any other footing short of discrediting them; that lawyers will not forego the possibility of adducing biased testimony, unless, indeed, they are compelled so to do, as by the application of the "Anthony plan"; the last objection is that certain professional experts will not willingly fall in with the suggestion. In answer to the last objection it may be affirmed that any expert witness who declined to consult with colleagues in this sense prior to the forensic examination would have difficulty in persuading a jury of his *bona fides.* In the United States objection has been raised, only to be overruled, that such an admission cannot be extracted from an expert witness under examination. If the question has been propounded in the presence of the person examined, it is admitted as a part of what was said and done in that presence, and even if it is made to the physician himself it will be admitted as a question bearing upon his credibility and bias. Dr. Anthony claims that his plan deprives "the ambulance chaser" of his chief reliance, it adds to the self-respect of all physicians who testify in court, and chiefly it is the first step to the elevation of expert testimony, for the plan is as applicable in other lines as in that of medical testimony.

The London Parks as Sleeping Places.

Apparently there is a regulation for the benefit of those frequenting the London public parks under which authority is given to those in charge of them to prevent idle and disorderly persons from lying about on the grass and from occupying the seats. Relying upon this regulation a park constable on duty on Primrose Hill recently tried to induce a man, described as a labourer, who was lying on the grass, to move on, and was saluted by him with a volley of bad language in reply. The man was arrested and brought before Mr. Paul Taylor at Marylebone police-court, but apparently the learned magistrate was not in sympathy with the regulation or with the park constable's manner of enforcing it, although the defendant was described by the constable as a perfect pest to the park, continually lying about in it. Mr. Taylor was of opinion that lying about in the park did not prove him to be an idle and a disorderly person and suggested as a parallel that he himself might be arrested if he chose to rest on the grass in Hyde Park, where, as he said, no doubt with truth, many people habitually lie. He was of opinion that proof of uncleanliness was necessary and he dismissed the charge. We are not altogether in agreement with Mr. Taylor who suggested that there might be a danger lest the police should arrest or bring a criminal charge against respectable poor people going to the parks to enjoy the fresh air. The respectable poor, and, indeed, respectable people who are not to be classed as poor, together with their children, find their healthy enjoyment of the open and grassy spaces provided for their recreation and pleasure curtailed and interfered with by the presence of loafers and idlers of both sexes sprawling on the grass. These are in some cases filthy and verminous but not in all. Many of them are idlers who contrive to live well and to keep themselves a little above the condition to which rags are appropriate. Their wives work hard to support them or in other ways they pick up as much money as they require without any exertion on their own part. The police can be trusted to exercise discretion and to distinguish between disreputable loafers and citizens of the humbler class. The parks are not maintained as sleeping places for those who in summer make use of them in order to save the expense of beds in common lodging-houses and Salvation Army shelters.

Hypnotism as an Excuse for Crime.

To judge from the reports of French criminal trials which appear in the daily papers from time to time, accused persons in France are ready to put forward defences which are never heard of in this country. In a case reported on Monday last, a young man charged in the first instance with the murder of two persons admitted the fact but declared that at the time he was under the hypnotic influence of a certain medical man who often mesmerised him. "I had fallen asleep," he said, "when the spell came upon me, I fought against it but was compelled against my will to go to the Prince's house and strike at the Princess and her nephew." The medical man in question denies that he had exercised any influence in the matter. We do not know whether this defence is to be solemnly put forward in a court of justice; we can only say that it would meet with but short shrift before a judge and jury in this country. As English law now stands we imagine that a man might as well plead drunkenness as an excuse for his misdeeds as allege that he was acting under the hypnotic influence of a third party. The defence of insanity would be out of the question. It has long been the law that to establish a defence on the ground of insanity it must be clearly proved that at the time of the committing of the act the party accused was labouring under such a defect of reason from disease of the mind as not to know the nature and quality of the act which he was doing, or, if he did know it, that he did not know he was doing what was wrong. The accused has himself done his best to place his case outside this category by saying that he fought against the evil influence brought to bear upon him.

Assaults on Officials Discharging their Duties.

In two cases heard on the same day, the one at the Tower Bridge police-court and the other at the Thames police-court, serious assaults were proved to have been committed upon officials employed to enforce the law. In the first a perfumer named Albert Lowen had attacked a factory inspector named Davis who had called at the defendant's premises in Westminster Bridge-road with reference to his failure to put up an abstract as required by the Factory Acts. The defendant asked for proof of the inspector's authority and was shown it, but nevertheless attacked him savagely and threw him violently into the street, inflicting upon him injuries which delayed the hearing of the charge from March 12th until May 30th. The defendant's excuse was that he did not see what was on the parchment, and thought that Mr. Davis was an impostor, and witnesses on behalf of the defendant alleged that Mr. Davis had abused the defendant and behaved in an unjustifiable manner. Mr. Rose appears to have disbelieved these allegations, for he described the assault as an outrageous and aggravated one, inflicting a fine of £5 with the alternative of one month's imprisonment. In the other case referred to five persons—Aaron Selway, Harris and Annie Lupinsky, Esther Oheleboloff, and Ada Matznow were charged with harbouring smuggled saccharin and were ordered to pay fines ranging from £70 to £3, with alternatives of varying terms of imprisonment for that offence. It was shown, however, by the evidence that when the seizure of the saccharin took place and while a large quantity of it was being thrown out of window by some of the defendants Mr. J. H. Davies, a preventive inspector, was violently assaulted, and Mr. A. W. Cope, a supervisor who accompanied him, was threatened with a knife. In the circumstances described the fines inflicted in both cases seem scarcely to constitute sufficiently heavy punishment to act as a deterrent against similar assaults. Factory inspectors, sanitary inspectors, medical officers of health, and many others, besides officers connected with the collection of revenue of various kinds, are often compelled to visit the houses of strangers and to perform tasks which render them highly obnoxious to persons of a very rough class. They are not selected and trained with a view to their defending themselves against violence like police constables and often act without police assistance and they are entitled to a full measure of protection from the law. The foreigners, moreover, who are so frequently offenders against the laws which have to be enforced by the officials in question are usually quite well aware that they are breaking the law and know perfectly well from experience in their own countries that they ought not to resist lawfully constituted authority with violence. If those who represent the law, on the other hand, transgress their conduct can be complained of in the proper manner.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE ELECTION TO THE COUNCIL.

AS we have already announced, on Thursday, July 2nd, the Fellows of the College *will elect four Fellows to fill the* vacancies on the Council. Every year three members of Council retire and those due to retire this year are Mr. J. Ward Cousins, Mr. A. Pearce Gould, and Mr. W. Harrison Cripps. Mr. F. Howard Marsh has resigned two years before the termination of his period of office and therefore there will be four vacancies to be filled. Mr. Ward Cousins was first elected in 1895 as a substitute member, again as a substitute member in 1897, and again in 1900. Mr. Pearce Gould was elected in 1900 and is a candidate for re-election. Mr. Harrison Cripps was elected in 1905 as a substitute member, and he also will no doubt apply for re-appointment. Other candidates are Mr. W. Arbuthnot Lane, Mr. J. Lynn Thomas, Mr. George Eastes, and Mr. William Frederick Haslam. It is probable that Mr. C. B. Lockwood will also be a candidate. At the forthcoming election the successful candidate who receives the smallest number of votes will serve as substitute member for Mr. Howard Marsh and will retire in 1910. The following table gives the dates at which the several members of the *Council will retire.*

In 1909.—Mr. W. Watson Cheyne, first elected 1897.
Mr. A. W. Mayo Robson, first elected 1893.
Mr. R. Clement Lucas.
In 1910.—Mr. J. H. Morgan.
Mr. H. H. Clutton.
In 1911.—Mr. H. T. Butlin, first elected 1895.
Mr. Clinton C. Dent.
Mr. G. H. Makins.
In 1912.—Mr. F. S. Eve, first elected 1904.
Mr. A. A. Bowlby.
Mr. G. Barling.
In 1913.—Mr. Rickman J. Godlee, first elected 1897.
Mr. Edmund Owen, first elected 1897.
Mr. C. H. Golding-Bird.
In 1914.—Mr. H. Morris (President), first elected 1893.
Mr. F. Richardson Cross, first elected 1898.
Mr. G. A. Wright.
In 1915.—Mr. C. W. Mansell Moullin, first elected 1902.
Mr. W. Bruce Clarke.
Mr. Charters J. Symonds.

BRITISH MEDICAL BENEVOLENT FUND.

AT the May meeting of the committee 22 cases were considered and grants amounting to £156 were made to 17 of the applicants. A vacant annuity was filled by the election of an approved candidate. Appended is an abstract of the cases relieved:—

Widow, aged 64 years, of L.F.P.S. Glasg. Since husband's death, after a long illness, about a year ago, applicant has endeavoured to support herself by letting lodgings. No children. Voted £5, with leave to apply again in six months if necessary.

Widow, aged 57 years, of L.F.P.S. Glasg. Left quite unprovided for at husband's death about 10 years ago. Nine children who do all that is possible. Relieved nine times, £125. Voted £5.

Daughter, aged 37 years, of late M.D. Glasg. Is a daily companion to an invalid lady, but earnings are insufficient for her own maintenance and a little help she is obliged to give her mother. Relieved four times, £22. Voted £5.

Daughter, aged 66 years, of late M.R.C.S. Has supported herself for many years but is now dependent on relations and is a candidate for the Epsom pension. Voted £5.

M.R.C.S., aged 67 years. Is incapacitated by hemiplegia and dependent on a son whose earnings are small. Voted £5.

M.R.C.S., L.S.A., aged 68 years. For some time past has been quite incapacitated by paralysis and heart disease. Eight children, of whom only three are entirely self-supporting. Has a small pension from a board of guardians but it is quite inadequate for unavoidable expenses. Relieved six times, £90. Voted £12.

Daughter, aged 76 years, of late M.R.C.S. Has a small annuity and hopes shortly to be elected to a U.K.B.A. pension, but requires a little help meantime. Relieved once, £12. Voted £5.

Daughter, aged 52 years, of late M.R.C.S., L.S.A. No income and regular work impossible owing to bad health. Relieved twice, £20. Voted £10.

Daughters, aged 47 and 45 years, of late M.R.C.S., L.R.C.P. No income; endeavour to support themselves by letting lodgings in the summer and by knitting in the winter. Relieved eight times, £37. Voted £12.

Daughter, aged 66 years, of late M.D. No income and only able to obtain occasional employment. Relieved ten times, £91. Voted £12.

Widow, aged 43 years, of L.R.C.P., L.R.C.S. Edin. Quite unprovided for at husband's death several years ago and is in extremely bad health. Is assisted by the Ladies' Working Guild. Children unable to help. Relieved 13 times, £148. Voted £12.

Daughter, aged 51 years, of late L.R.C.P. Edin. No income. Is a great sufferer from rheumatic gout and dependent for a home on two unmarried sisters who have to earn their own living. Relieved three times, £26. Voted £10.

Widow, aged 51 years, of L.R.C.P.I. No income and has not yet recovered from the effects of a very serious operation. Relieved once, £12. Voted £12.

Daughter, aged 51 years, of late M.D. Lond. Income £20 a year from the Home for Incurables. Has had a serious illness during the winter and in consequence lost a lodger and is in arrears with rent. Relieved nine times, £81. Voted £10.

Widow, aged 67 years, of M.D. Edin. Children unable to help and is dependent on this fund and a little assistance given locally. Relieved four times, £42. Voted £15.

Widow, aged 61 years, of L.R.C.P., L.R.C.S. Edin. Has a small pension from a City company, but it is insufficient for bare necessities and children are unable to help. Relieved once, £6. Voted £6.

Wife, aged 43 years, of L.R.C.P., L.R.C.S. Edin., who is confined in an asylum. No income; dependent on a sum collected locally and now nearly exhausted, and earns a few shillings a week by fancy work. Two children, aged 15 and 12 years. Relieved once, £15. Voted £15.

Looking Back.

FROM

THE LANCET, *SATURDAY*, June 5th, 1830.

NON-APPOINTMENT OF SURGEONS TO TRADING VESSELS.

To the Editor of THE LANCET.

SIR,—To me it has often been a subject of surprise, that among the many laws which are enacted by our legislature, none has ever compelled merchant-vessels of a certain tonnage, and having on board a certain number of men, to carry a surgeon. Such a defect in our maritime laws becomes still more singular, when we call to mind the high mercantile character of the British nation, and the consequent necessity for protecting the health and lives of those employed in it. That a medical man ought to be numbered amongst the crew of all large ships bound to distant parts, is what the public have a right to expect; it is what the seamen, their relatives, and their friends, have a right to demand; but that a south-seaman in particular, bound on a whaling voyage, should be allowed to sail from a British port without any medical officer on board, is a deep stain upon the humanity for which England has ever been renowned. It is true a still heavier blame, amounting to criminality, is attached to the South-sea ship-owners individually, but experience teaches us we are not to depend upon the generous and benevolent feelings which ought to actuate those whom the labour of many poor men enriches. Such *feelings are too* often absent. A close and lengthened application to a profitable business, frequently strips the heart of all that is noble, and renders it sensible to little but self-interest.

Whalers are generally from two to three years away from England, and no class of vessels, whether merchantmen or men-of-war, can, in time of peace, be exposed to one half the danger to which they are exposed. The crews are liable to every variety of malignant disease arising from vicissitude of climate; they are liable to innumerable accidents in the dangerous and frequently fatal employment of whaling; they are mostly in the habit of touching and refreshing at savage islands, where no medical attendance can be procured; they are, in fact, during these long, tedious, and hazardous voyages, separated from the *civilized world*, having but little communication with any, save with the semi-barbarous natives of the South-sea islands.

These, Sir, I think, are forcible arguments in favour of an act of parliament, obliging all vessels, but more especially whalers, whose complement of men consists of—say twenty and upwards, to carry a surgeon. This would not be imposing an unjust tax on *poor* merchants, as all who can fit out ships on whaling expeditions, must necessarily be considerable capitalists, and possess ample means of employing medical men. In short, humanity towards our sailors, the prop and support of the British nation, loudly calls upon those who have it in their power, to enact such a law.

I am, Sir, your obedient servant,
G. E. LANGTON.
Camberwell, May 26, 1830.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8915 births and 3917 deaths were registered during the week ending May 30th. The annual rate of mortality in these towns, which had declined in the four preceding weeks from 15·7 to 13·2 per 1000, further fell to 12·6 in the week under notice. During the first nine weeks of the current quarter the annual death-rate in these towns averaged only 14·6 per 1000, and in London during the same period the rate did not exceed 14·3. The lowest annual death-rates in the 76 towns during the week under notice were 4·5 in Hornsey, 5·6 in Willesden, 5·8 in East Ham, and 6·6 in Leyton and in Halifax; the rates in the other towns ranged upwards to 20·1 in Oldham, 20·3 in Burnley, 20·4 in Stockport, 20·9 in Merthyr Tydfil, and 21·5 in Wigan. The death-rate in London during the week did not exceed 11·7. The 3917 deaths in the 76 towns during the week showed a further decline of 180 from the numbers returned in the four preceding weeks, and included but 288 which were referred to the principal epidemic diseases, against numbers declining from 445 during the eight preceding weeks; of these 288 deaths, 75 resulted from whooping-cough, 72 from measles, 47 from diarrhœa, 39 from scarlet fever, 36 from diphtheria, and 19 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases last week were equal to an annual rate of 0·9 per 1000, which was considerably below the rate in any previous week of this year; the rate from these diseases in London did not exceed 0·7 per 1000. No death from any of these epidemic diseases was registered last week in Leicester, Willesden, Blackburn, Walthamstow, or in 14 other smaller towns; the annual death-rates from these diseases ranged upwards, however, to 2·5 in West Ham and in Burnley, 2·7 in Merthyr Tydfil, 3·0 in Middlesbrough, and 3·1 in Aston Manor. The fatal cases of whooping-cough in the 76 towns, which had been 121 and 114 in the two preceding weeks, further declined to 75 in the week under notice; this disease caused the highest death-rates, 1·5 in Burnley, 1·6 in Rotherham, and 2·7 in Merthyr Tydfil. The 72 deaths from measles also showed a considerable further decline from recent weekly numbers, but caused death-rates equal to 1·5 in Stockport and in Wallasey, 1·7 in West Ham, and 1·8 in Preston. The 47 deaths attributed to diarrhœa showed a slight increase, and were proportionally most numerous in St. Helens and Middlesbrough. The 39 fatal cases of scarlet fever showed a further small increase upon recent weekly numbers, and included 13 in London and its suburban districts, six in Liverpool, six in Manchester and Salford, and two in Leeds and in Reading. Of the 36 deaths from diphtheria, also showing an increase, 11 occurred in London and two in Bristol, in Portsmouth, in Aston Manor, in Derby, and in Gateshead. Two of the 19 deaths from "fever" were recorded in Newcastle-on-Tyne. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had declined from 2938 to 2802 in the four preceding weeks, had further fallen to 2753 on May 30th; 334 new cases were admitted to these hospitals during the week under notice, against 380 and 330 in the two preceding weeks. The deaths in London referred to pneumonia and to other diseases of the respiratory organs, which had steadily declined in the five preceding weeks from 301 to 194, further fell to 147 during the week under notice, and were 51 below the corrected average number in the corresponding week of the five years 1903–07. Only eight deaths were directly referred to influenza in London, showing a marked decline from recent weekly numbers. The causes of 34, or 0·9 per cent., of the deaths registered last week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were again duly certified in Leeds, Manchester and Salford, Bristol, West Ham, Bradford, and in 47 other smaller towns; five uncertified causes of death were, however, registered in Birmingham and King's Norton, three in St. Helens, and three in Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 15·3 and 15·4 per 1000 in the two preceding weeks, further rose slightly to 15·5 in the week ending May 30th. During the first nine weeks of the current quarter the annual death-rate in these eight towns averaged 17·4 per 1000, and exceeded by no less than 2·8 the mean rate during the same period in the 76 large English towns. Among the eight Scotch towns the death-rate during the week under notice ranged from 12·3 and 12·7 in Aberdeen and Dundee to 17·8 in Perth and 17·9 in Leith. The 546 deaths in the eight towns (against 541 and 542 in the two preceding weeks) included 54 which were referred to the principal epidemic diseases, showing a slight increase upon the low numbers returned in the two preceding weeks; of these 54 deaths, 17 resulted from diarrhœa, 16 from measles, 13 from whooping-cough, five from diphtheria, two from "fever," and one from scarlet fever, but not one from small-pox. These 54 deaths were equal to an annual rate of 1·5 per 1000, the mean rate from the same diseases in the 76 English towns during the same week not exceeding 0·9. The 17 deaths attributed to diarrhœa in the Scotch towns exceeded the numbers in recent weeks and included eight in Glasgow and three in Dundee and in Aberdeen. The 16 fatal cases of measles also exceeded the number in the previous week; seven were returned in Glasgow, five in Edinburgh, and two both in Paisley and in Leith. Of the 13 deaths from whooping-cough, also showing an increase, eight occurred in Glasgow, two in Aberdeen, and two in Paisley. Of the five fatal cases of diphtheria, also exceeding the low numbers in recent weeks, three occurred in Glasgow and two in Leith. The two deaths from "fever," both certified as due to cerebro-spinal meningitis, were returned in Glasgow; the deaths from this disease in the eight towns were fewer than in any recent week. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 119, 79, and 77 in the three preceding weeks, rose to 85 in the week under notice, and exceeded by two the number returned in the corresponding week of last year. The causes of 16, or 3·0 per cent., of the deaths in these eight towns during the week were not certified or not stated; in the 76 English towns the proportion of uncertified causes of death in the same week was 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 19·0 and 22·2 per 1000 in the two preceding weeks, declined to 15·9 in the week ending May 30th, and was considerably lower than in any previous week of this year. During the first nine weeks of the current quarter the death-rate in Dublin averaged 21·9 per 1000; the mean rate during the same period did not exceed 14·3 in London and 15·9 in Edinburgh. The 120 deaths of Dublin residents registered during the week under notice showed a decline of 48 from the number returned in the previous week and included six which were referred to the principal epidemic diseases, against six and four in the two preceding weeks. These six deaths were equal to an annual rate of 0·8 per 1000, the rate during the week from the same diseases being 0·7 in London and 0·9 in Edinburgh. Of the six deaths from these epidemic diseases in Dublin, three resulted from diarrhœa, two from diphtheria, and one from measles, but not one from scarlet fever, whooping-cough, "fever," or small-pox. The 120 deaths from all causes in the city during the week under notice included 20 of infants under one year of age and 36 of persons aged upwards of 60 years; the deaths of elderly persons were considerably fewer than in any previous week of this year. Five inquest cases and four deaths from violence were registered, and 53, or 44·1 per cent., of the deaths occurred in public institutions. The causes of all but one of the deaths during the week were duly certified. The causes of all but one of the 1073 deaths in London were also duly certified, but more than 5 per cent. of the causes of death in Edinburgh were uncertified.

THE R.A.M.C. CAMP AT BULFORD.—The R.A.M.C. camp of instruction was formed at Bulford on June 1st, the officers and men being drawn from the out-stations of the Southern Command. Ten officers and 182 non-commissioned officers and men are under canvas.

resist lawfully constituted authority with violence. If those who represent the law, on the other hand, transgress their conduct can be complained of in the proper manner.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE ELECTION TO THE COUNCIL.

AS we have already announced, on Thursday, July 2nd, the Fellows of the College will elect four Fellows to fill the vacancies on the Council. Every year three members of Council retire and those due to retire this year are Mr. J. Ward Cousins, Mr. A. Pearce Gould, and Mr. W. Harrison Cripps. Mr. F. Howard Marsh has resigned two years before the termination of his period of office and therefore there will be four vacancies to be filled. Mr. Ward Cousins was first elected in 1895 as a substitute member, again as a substitute member in 1897, and again in 1900. Mr. Pearce Gould was elected in 1900 and is a candidate for re-election. Mr. Harrison Cripps was elected in 1905 as a substitute member, and he also will no doubt apply for re-appointment. Other candidates are Mr. W. Arbuthnot Lane, Mr. J. Lynn Thomas, Mr. George Eastes, and Mr. William Frederick Haslam. It is probable that Mr. C. B. Lockwood will also be a candidate. At the forthcoming election the successful candidate who receives the smallest number of votes will serve as substitute member for Mr. Howard Marsh and will retire in 1910. The following table gives the dates at which the several members of the Council will retire.

In 1909.—Mr. W. Watson Cheyne, first elected 1897.
Mr. A. W. Mayo Robson, first elected 1893.
Mr. R. Clement Lucas.
In 1910.—Mr. J. H. Morgan.
Mr. H. H. Clutton.
In 1911.—Mr. H. T. Butlin, first elected 1895.
Mr. Clinton C. Dent.
Mr. G. H. Makins.
In 1912.—Mr. F. S. Eve, first elected 1904.
Mr. A. A. Bowlby.
Mr. G. Barling.
In 1913.—Mr. Rickman J. Godlee, first elected 1897.
Mr. Edmund Owen, first elected 1897.
Mr. C. H. Golding-Bird.
In 1914.—Mr. H. Morris (President), first elected 1893.
Mr. F. Richardson Cross, first elected 1898.
Mr. G. A. Wright.
In 1915.—Mr. C. W. Mansell Moullin, first elected 1902.
Mr. W. Bruce Clarke.
Mr. Charters J. Symonds.

BRITISH MEDICAL BENEVOLENT FUND.

AT the May meeting of the committee 22 cases were considered and grants amounting to £156 were made to 17 of the applicants. A vacant annuity was filled by the election of an approved candidate. Appended is an abstract of the cases relieved:—

Widow, aged 64 years, of L.F.P.S. Glasg. Since husband's death, after a long illness, about a year ago, applicant has endeavoured to support herself by letting lodgings. No children. Voted £5, with leave to apply again in six months if necessary.

Widow, aged 57 years, of L.F.P.S. Glasg. Left quite unprovided for at husband's death about 10 years ago. Nine children who do all that is possible. Relieved nine times, £125. Voted £5.

Daughter, aged 37 years, of late M.D. Glasg. Is a daily companion to an invalid lady, but earnings are insufficient for her own maintenance and a little help she is obliged to give her mother. Relieved four times, £22. Voted £5.

Daughter, aged 66 years, of late M.R.C.S. Has supported herself for many years but is now dependent on relations and is a candidate for the Epsom pension. Voted £5.

M.R.C.S., aged 67 years. Is incapacitated by hemiplegia and dependent on a son whose earnings are small. Voted £5.

M.R.C.S., L.S.A., aged 68 years. For some time past has been quite incapacitated by paralysis and heart disease. Eight children, of whom only three are entirely self-supporting. Has a small pension from a board of guardians but it is quite inadequate for unavoidable expenses. Relieved six times, £90. Voted £12.

Daughter, aged 76 years, of late M.R.C.S. Has a small annuity and hopes shortly to be elected to a U.K.B.A. pension, but requires a little help meantime. Relieved once, £12. Voted £5.

Daughter, aged 52 years, of late M.R.C.S., L.S.A. No income and regular work impossible owing to bad health. Relieved twice, £22. Voted £10.

Daughters, aged 47 and 45 years, of late M.R.C.S., L.R.C.P. No income; endeavour to support themselves by letting lodgings in the summer and by knitting in the winter. Relieved eight times, £37. Voted £12.

Daughter, aged 66 years, of late M.D. No income and only able to obtain occasional employment. Relieved ten times, £91. Voted £12.

Widow, aged 43 years, of L.R.C.P., L.R.C.S. Edin. Quite unprovided for at husband's death several years ago and is in extremely bad health. Is assisted by the Ladies' Working Guild. Children unable to help. Relieved 13 times, £148. Voted £12.

Daughter, aged 51 years, of late L.R.C.P. Edin. No income. Is a great sufferer from rheumatic gout and dependent for a home on two unmarried sisters who have to earn their own living. Relieved three times, £26. Voted £10.

Widow, aged 51 years, of L.R.C.P.I. No income and has not yet recovered from the effects of a very serious operation. Relieved once, £12. Voted £12.

Daughter, aged 51 years, of late M.D. Lond. Income £20 a year from the Home for Incurables. Has had a serious illness during the winter and in consequence lost a lodger and is in arrears with rent. Relieved nine times, £81. Voted £10.

Widow, aged 67 years, of M.D. Edin. Children unable to help and is dependent on this fund and a little assistance given locally. Relieved four times, £42. Voted £15.

Widow, aged 61 years, of L.R.C.P., L.R.C.S. Edin. Has a small pension from a City company, but it is insufficient for bare necessities and children are unable to help. Relieved once, £6. Voted £6.

Wife, aged 43 years, of L.R.C.P., L.R.C.S. Edin., who is confined in an asylum. No income; dependent on a sum collected locally and now nearly exhausted, and earns a few shillings a week by fancy work. Two children, aged 15 and 12 years. Relieved once, £15. Voted £15.

Looking Back.

FROM

THE LANCET, *SATURDAY*, June 5th, 1830.

NON-APPOINTMENT OF SURGEONS TO TRADING VESSELS.

To the Editor of THE LANCET.

SIR,—To me it has often been a subject of surprise, that among the many laws which are enacted by our legislature, none has ever compelled merchant-vessels of a certain tonnage, and having on board a certain number of men, to carry a surgeon. Such a defect in our maritime laws becomes still more singular, when we call to mind the high mercantile character of the British nation, and the consequent necessity for protecting the health and lives of those *employed* in it. That a medical man *ought* to be numbered amongst the crew of all large ships bound to distant parts, is what the public have a right to expect; it is what the seamen, their relatives, and their friends, have a right to demand; but that a south-seaman in particular, bound on a whaling voyage, should be allowed to sail from a British port without any medical officer on board, is a deep stain upon the humanity for which England has ever been renowned. It is true a still heavier blame, amounting to criminality, is attached to the South-sea ship-owners individually, but experience teaches us we are not to depend upon the generous and benevolent *feelings* which ought to actuate those whom the labour of many poor men enriches. Such feelings are too often absent. A close and lengthened application to a profitable business, frequently strips the heart of all that is noble, and renders it sensible to little but self-interest.

Whalers are generally from two to three years away from England, and no class of vessels, whether merchantmen or men-of-war, can, in time of peace, be exposed to one half the danger to which they are exposed. The crews are liable to every variety of malignant disease arising from vicissitude of climate; they are liable to innumerable accidents in the dangerous and frequently fatal employment of whaling; they are mostly in the habit of touching and refreshing at savage islands, where no medical attendance can be procured; they are, in fact, during these long, tedious, and hazardous voyages, separated from the civilized world, having but little communication with any, save with the semi-barbarous natives of the South-sea islands.

These, Sir, I think, are forcible arguments in favour of an act of parliament, obliging all vessels, but more especially whalers, whose complement of men consists of—say twenty and upwards, to carry a surgeon. This would not be imposing an unjust tax on *poor* merchants, as all who can fit out ships on whaling expeditions, must necessarily be considerable capitalists, and possess ample means of employing medical men. In short, humanity towards our sailors, the quantity and but little advance in our knowledge will be gained by its use. If the vaccines can be given by this method it will be a great point gained, though one cannot but fear that under the varying conditions of alimentary absorption accuracy of dosage will be impossible to attain. But, at any rate, let us decide first of all by the simple means at our disposal whether they are absorbed or not.

I am, Sir, yours faithfully,

Devonshire-street, W., May 27th, 1908. CLIVE RIVIERE.

CONVEYANCE OF THE INFECTION OF CHICKEN-POX BY A THIRD PERSON.

To the Editor of THE LANCET.

SIR,—The possibility that chicken-pox may be conveyed by a third person, who is not suffering from the disease, is shown by the following case. I was called in on March 12th last to see a single woman, aged 30 years, suffering from the effects of an attack of influenza, which she was said to have had about a month previously. On March 14th symptoms of jaundice presented themselves and she remained in bed, isolated from the rest of the family except for her parents. The following Monday, March 16th, acute toxæmic jaundice supervened and the patient was placed in charge of two trained nurses, her parents seeing her occasionally only. The following Saturday I saw a young girl living in the house, whom I found to be suffering from a mild attack of chicken-pox, contracted at a day school. The attack was a very mild one and I ordered frequent disinfectant baths, at the same time taking care to isolate as far as possible my other patient by cutting all communication with the sick room, except for the parents, to whom I gave directions accordingly. On April 8th the elder patient, who so far had been progressing favourably and was recovering from her original illness, became suddenly worse, being delirious, her temperature, which had been subnormal (97·2° F.), rising to 99·8° and her pulse to 130 and higher. She remained in this condition for 48 hours and on April 10th a dense chicken-pox rash appeared, covering her thickly from head to foot, many of the spots rapidly becoming pustular and then breaking down into large ulcers, some one-third of an inch across, and penetrating into the subcutaneous tissues. The patient's condition remained critical for another 48 hours and then slowly began to mend, becoming convalescent by the end of the month. No other case of chicken-pox occurred in the house.

The infection in this case was evidently conveyed by some person who did not have the disease, probably by the parents, neither of whom ever showed any trace of the disease, both having had it many years before. The two patients with chicken-pox had not been in contact since March 13th and the elder had not been outside her bedroom for four weeks previously to the rash appearing in her case.

I am, Sir, yours faithfully,

May 30th, 1908. ERNEST F. TRAVERS, M.D. Lond.

THE SPIROGRAPH.

To the Editor of THE LANCET.

SIR,—Two weeks ago a criticism of my book on "Diagnosis in Diseases of the Throat, Nose, and Ear" appeared in THE LANCET. In that criticism it is stated that the spirograph attributed to Wingrave was invented by Sandemann many years ago. Such is not the case. Sandemann employed a square of cardboard sprinkled over with powdered slate or similar material. It was a lamentable failure. Wingrave's device is described in my book. It is a perfect success. The first qualification for a critic, especially a critic attached to THE LANCET, is a sound knowledge of his subject. Otherwise criticism becomes presumption.

I am, Sir, yours faithfully,

Stratford-place, W., May 21st, 1908. DAN. MCKENZIE.

To the Editor of THE LANCET.

SIR,—Thank you for allowing me to see the courteous strictures of Dr. McKenzie. I take the liberty of pointing out in reply that Sandmann's method was described in a paper read in Berlin in 1893, perhaps a little too early for Dr. McKenzie to know much about it; that "powdered slate" was not used; that Sandmann's method gave a *permanent* record; and that the temporary method advocated by Dr. McKenzie is precisely that first adopted by Sandmann. (The paper is published in the *Journal of Laryngology*, February, 1894.)—I am, Sir, yours faithfully,

May 27th, 1908. THE REVIEWER.

"THE OLDEST INSTITUTION FOR TREATING SICK CHILDREN."

To the Editor of THE LANCET.

SIR,—A copy of the *British Press* (price 7*d.*) for Monday, April 29th, 1816, has recently come into the possession of the board of governors. It contains a two-column report of the foundation meeting of the hospital held at the City of London Tavern on the previous Saturday, at which T.R.H. the Dukes of Kent and Sussex were present, with the Lord Mayor, the Sheriffs, and a numerous company of ladies and gentlemen. The two former were the first subscribers of £20 each and the latter £10 each. The institution thus created was named "The Royal Universal Infirmary for Children," and after several variations of name, and one change of site, but in unbroken succession, it is now known as the Royal Waterloo Hospital for Children and Women, and so has been continuously at work for more than 90 years.

I am, Sir, yours faithfully,

J. HOUSTON,

Organising Secretary of the Special Appeal Committee of the Royal Waterloo Hospital.

THE GRÆCO-ROMAN BRANCH OF THE EGYPT EXPLORATION FUND.

To the Editor of THE LANCET.

SIR,—Will you kindly permit me the haven of your correspondence column to advocate the claims of what is known as the "Græco Roman Branch of the Egypt Exploration Fund." This fund is for the purpose of recovering ancient papyri from the sands of Egypt by means of excavations upon the sites of the old Greek and Roman cities there. And the number of fragments of classic medical works already discovered, including the priceless manuscript of the Hippocratic treatise, "The Iatrica of Menon," is quite considerable. The reports of municipal medical officers and particulars of taxes and imposts for medical purposes found from time to time are most interesting. Further medical manuscripts will almost certainly be procured, but the society is, unfortunately, inactive temporarily for want of funds. A subscription of 21*s.* or upwards entitles donors to the annual volume and will help this most deserving society.

I am, Sir, yours faithfully,

Bedford Park, W., May 26th, 1908. JOSEPH OFFORD.

PS.—The Fund's address is 37, Great Russell-street, Bloomsbury, London, W.C.

THE FIRST INTERNATIONAL CONGRESS ON LARYNGOLOGY AND RHINOLOGY.

(FROM OUR VIENNA CORRESPONDENT.)

(*Concluded from p. 1445.*)

Diagnostic and Therapeutic Applications of the X Rays.

Professor BURGER (Amsterdam) read a paper on the Value of the X Rays in Rhino-Laryngology. He said that this method had many advantages in certain branches of medicine. It enabled the ossification of the bones to be studied; it showed the mechanism of singing, speaking, and deglutition; and it clearly displayed the position of foreign bodies in the œsophagus and the bronchi. It was not possible to obtain with the x rays the same good results as with direct œsophago-bronchoscopy, but the use of the x rays was much easier and did not require so much special experience. The rays had little value for the differential diagnosis of neoplasmata but the diagnosis of diseases of the accessory sinuses of the nose, especially when used in the sagittal direction, was much helped by them, for they enabled an opinion to be formed as to the condition of the maxillary, the sphenoidal, and the frontal sinuses. Instruments might be used in these sinuses under the guidance of the rays. Electric transillumination gave better results in disease of the maxillary antrum and the x rays in disease

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeons: J. Bradley to the *Ocean*, on recommissioning; G. H. Foott to the *Victorious*; A. M. Page to the *London*. Staff-Surgeons: T. W. Philip to the *Russell*, on recommissioning; J. W. W. Stanton to the *Illustrious*, on recommissioning; H. Spicer to the *Repulse*. Surgeons: F. Cock to the *Russell*, on recommissioning; M. T. Male to the *Mars*, on recommissioning; B. S. Robson to the *Spanker*, on completing; and D. H. Vickery to the *Illustrious*, on recommissioning.

ARMY MEDICAL SERVICE.

The transfer from the Supernumerary List of Colonel W. Babtie, V.C., C.M.G., bears date May 13th, 1908.

ROYAL ARMY MEDICAL CORPS.

Lieutenant James C. L. Hingston is confirmed in that rank.

Captain F. M. Parry, from the London District, has been appointed to the Eastern Command from August 1st. Captain L. V. Thurston, on return from leave, has been posted to Jubbulpore for duty.

"LORD ROBERTS'S BOYS."

The report by the executive committee to the council of the City of London Schoolboys' Shooting Club for 1906–07 is an interesting little pamphlet giving an account of the work done by the boys in camp and embellished with a reproduction of a photograph of the Astor Cup team at Bisley (1907) and a coloured picture of the headquarters hut for the "Lord Roberts's Boys" at Bisley, 1908. The report states that the 1907 season was a most successful one. Facilities have now been provided in the City of London for drill and rifle shooting for all schoolboys and each school possesses its school cadet corps. "All we now require," says the committee, "is permission from the Board of Education to draft instructors to school premises once or twice a week, at convenient times, for drill of a military type."

THE ALLOCATION OF OFFICERS' CABINS.

An important circular letter has been issued by the Admiralty relating to improved rules with regard to cabin *accommodation for officers on board ships of war. In future* a captain is to allow every officer to occupy a cabin allotted according to his rank, and special cabins will be given to medical officers amongst others, the selection being made with special reference to official duties.

Correspondence.

"Audi alteram partem."

THE TREATMENT OF PULMONARY TUBERCULOSIS BY A POSTURAL METHOD,

ENCOURAGING DRAINAGE OF THE LUNG AND INDUCING ARTIFICIAL HYPERÆMIA OF THE APEX.

To the Editor of THE LANCET.

SIR,—The favourable account which Dr. A. T. Tucker Wise is able to give of the *prone posture* in the treatment of phthisis will not be a surprise to those who may have tried it in patients suffering from other affections as well as for themselves in health. Its advantages are cardiac as well as respiratory. The weight of the heart being completely removed from the diaphragm and from the roots of the lungs the posterior lobes, particularly at the base, are allowed great freedom of expansion, and this in itself eases the circulation through the heart. In phthisis great value must attach to this cardio-pulmonary advantage, as I have found it a help in various conditions of lowered vitality. I first resorted to it some years ago for the treatment of rickets, but it was not until three years ago that I commenced the long-delayed construction of the "infant-rest" and of the "all fours exerciser,"[1] and subsequently of the "convalescent machine,"[2] which provides among many other uses the same facilities as the exerciser. These appliances, as stated in my paper on the "Empty Bronchus" Treatment by Posture in the Bronchiectasis of Children,[3] owing to their adaptability to a variety of purposes and of ages, are specially suitable for hospitals and institutions. Dr. Tucker Wise's prone couch has the advantage of greater simplicity and cheapness whilst answering the individual requirements of the case of phthisis.

The systematic employment of the *inclined prone posture* is, I believe, an entirely new departure in the treatment of pulmonary tuberculosis. Judging from Dr. Tucker Wise's experience it is likely to be a permanent addition to our therapeutical methods. My own previous use of that posture had been occasional only; and it was limited to an endeavour to empty the basic cavities of phthisis, and on the other hand to convey into the cavities at the apex injections introduced through the trachea, an attempt which has since then been much more efficiently made by Colin Campbell by means of his ingenious "revolving chair." At the same time, the *continuous drainage* of bronchiectatic cavities by the inclined prone posture was one of the special purposes for which the machines were devised and have been used. But Dr. Tucker Wise's method claims in addition to secure for the treatment of phthisis a *passive hyperæmia* of the apices. In that respect it is most up-to-date, as Bier's therapeutical method has now led to the invention of Kühn's "pulmonary suction-mask," the latest fruit of the suggestion contained in Rokitansky's original observation (1846) as to the comparative infrequency of tubercle in the congested lung of mitral disease.

The respiratory indications of the *pulmonary rest cure* are thoroughly fulfilled by Dr. Tucker Wise's prone couch which favours the function of the posterior lobes. I must own, however, that the *cardio-pulmonary exercise-cure with local rest for the apices* provided by the prone posture on the convalescent machine had been uppermost in my mind in connexion with the sanatorium purposes of the machine. It was in that manner that I began using it last year for phthisis at St. George's Hospital. The graduated exercise which it provides can be strictly limited at first to the lower limbs, as the patient wheels himself about by the action of the feet; and the exertion can be started at a very low minimum of effort, as in the prone posture the weight of the body is entirely carried by the machine. For those who share these views as to the treatment of *pulmonary disease* Dr. Tucker Wise's most practical appliance might easily be modified and mounted upon wheels so as to answer the purposes of exercise as well as those of rest.

I am, Sir, yours faithfully,
WILLIAM EWART.

May 31st, 1908.

THE ADMINISTRATION OF VACCINES BY THE MOUTH.

To the Editor of THE LANCET.

SIR,—At the discussion on May 26th at the Royal Society of Medicine of Dr. A. Latham's paper on the Administration of Vaccines by the Mouth much was said of horse serum, and but little attention paid to the main question at issue—the absorption or non-absorption of tuberculin (and other vaccines) from the alimentary canal. May I crave space to bring forward a point which the meeting overlooked and time did not allow me to develop—namely, the utter impossibility of testing this method of vaccine administration on such a disease as phthisis. In this disease, as we all know, auto-inoculation is continually going on and the opsonic index is continually fluctuating, and in such unstable conditions the effect of a dose of tuberculin is really impossible to follow. I cannot persuade myself that Dr. Latham's opsonic charts prove anything at all.

On the other hand, the absorption or non-absorption of tuberculin given by the mouth can be readily decided once and for all if a case of *localised* tuberculosis is chosen, and it is curious that this test has not been already applied. Given a stationary opsonic index, the effect (or non-effect) of tuberculin per os is definite and certain. If it is absorbed a "tuberculin curve" will result; if it is not absorbed the opsonic index will remain as before. Till this test has been applied the value of tuberculin by the mouth in phthisis must remain an unknown

---

[2] Constructed by Messrs. J. Ward, 246, Tottenham Court-road, W.C.

[3] Medical Press and Circular, May 20th, 1908.

The term "infected" ship is limited to a ship on which there is actually on board at the time of arrival a case of cholera or plague within seven days before arrival, or a case of yellow fever within 18 days before arrival. At the same time the term "suspected" ship is used as applying to a ship on which there has been a case of cholera or plague more than seven days before the arrival of the ship, or a case of yellow fever more than 18 days before arrival, whether the case has occurred in the port of departure or in another port in the course of the voyage, or at any time during the voyage, and on which no fresh case of cholera or plague has occurred within seven days, or of yellow fever within 18 days. New provisions have also been made prescribing the procedure to be followed with a view to prevent the transmission of plague by rats on board ship and the escape from the ship to shore of rats that may be infected with plague. With a view to obviate the first of these dangers rats are in all cases to be destroyed when the ship is infected with plague or when rats in the ship are infected with that disease. In the case of a ship which is not infected, but is a suspected ship by reason of plague, this procedure is not obligatory, except where the medical officer of health requires it to be followed. Epidemics of plague have long been known to be almost invariably associated with similar outbreaks among rats and other animals, but it has only recently been universally recognised that the rat plague precedes, and is chiefly responsible for, the spread of plague amongst human beings. Bubonic plague in man is entirely dependent on disease in the rat. The infection is conveyed from rat to rat and from rat to man solely by means of the rat flea. The reader of the paragraphs on the dangers of infection by means of rats must be at a loss to know why, in the case of a "suspected" ship by reason of plague, the destruction of rats is not obligatory also. The report states that during the year 1907 3169 rats have been examined by the corporation bacteriologist.

Munificent Donation to the Royal Infirmary.

The executors of the late Mr. Edward Robert Bickersteth (for many years surgeon to the Royal Infirmary and latterly consulting surgeon) have intimated to the committee their intention of forwarding a cheque for £10,000 as a gift from the late Mr. Bickersteth towards the fund for the erection of the new out-patient department at the Royal Infirmary in which he took such a deep interest.

St. Paul's Eye and Ear Hospital: The Prevention of Blindness in Children.

The annual meeting of the supporters of this charity was held at the town-hall on May 25th, the Lord Mayor (Dr. Richard Caton) presiding. The report showed that during the year 1907 7328 cases of diseases of the eye, 1720 cases of diseases of the ear, and 56 unclassed cases were treated. There were 775 in-patients treated. The number of operations amounted to 1167. In accordance with the recommendation of the British Medical Association an almoner ad been appointed who would check, it was hoped, ny abuse of the charity. Owing to the number of ccidents in the workshops at the docks caused by teel chips which penetrate the eyeball and unless emoved inevitably cause its total destruction, an electro-agnet was purchased at a cost of £56. This had been uccessful in extracting the steel in every case which had ome to the hospital since its purchase. The medical staff ad been impressed with the inadequacy of the usual ethods of treating ophthalmia in newly born infants, and ey had taken advantage of the new Notification of Births d Registration of Midwives Acts to enlist the help of the unicipal health authorities in an effort to prevent its astrous results. A ward had been given up to the work d arrangements had been made for the admission of other and infant immediately on the detection of the disease. was believed that St. Paul's Hospital was the first to make h an organised effort to cope with a disease which s estimated by the Royal Commission on the Blind in 1889 be the cause of blindness of 7000 people in the United ogdom and to cost £350,000 annually. Dr. Arthur Nimmo lker, the secretary of the medical board of the hospital, seconding the re-election of honorary officers and members he committee, described in detail the arrangements which been made in the hospital to combat purulent ophthalmia newly born infants and emphasised the importance of ing hold of the infants in the earliest stage of the ase.

ne 2nd.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Crippled Children's Union.

THE annual report of the Birmingham and District Crippled Children's Union, which was presented at the recent annual meeting of the subscribers, refers with pride to past well done work and with increasing hope to a future of greater opportunities. During the past year 297 children were sent to convalescent homes at a cost of £800 and there can be no doubt that the subscribers will cordially indorse the managers' opinion that the money could not be spent in a more productive way so far as lasting curative results are concerned. The number of new cases dealt with during the year was 251 and the total number of cases 1085. The only drawback to the record of work done was the fact that it had resulted in a monetary deficit of £51 and consequently the total deficit is now £93. The hopeful outlook is due to Mr. George Cadbury's gift of a house and grounds at Northfield, to be used as a convalescent and nursing home. In this new home the society looks forward to being able to give to cases of tuberculous disease of bone that perfect rest and fresh air which are such necessary and efficient curative agents. To get the best possible results out of Mr. Cadbury's splendid gift and to make suitable provision for about 70 patients, 24 of whom will be undergoing open-air treatment, it will be necessary to spend about £4680—£3680 for re-arrangement and £1000 for furniture and fittings. To meet this expense the society possesses a building fund of £2400, therefore it will be necessary to appeal to the public for the remaining £2280. There can be little doubt that this comparatively small sum will be forthcoming if the committee places its claim clearly before the public, for the object of the society appeals strongly to all classes.

The Clearing of the Slums.

The report of the housing committee to the city council shows that the work of improving the slum area is proceeding regularly and satisfactorily, though it may be, on account of difficulties, slowly. In about six years the medical officer of health has reported 4532 houses as unfit for human habitation; of these 1213 have been taken down, 1608 have been converted into habitable places, 35 have become workshops, 317 are under repair, and notices are outstanding on the remainder. The committee reports that closing orders are never applied for until negotiations have utterly failed and it is its desire to preserve as many cheap small houses as possible in the city for the convenience of the working people. A part of the committee's scheme of work which is perhaps the most valuable is that which deals with the conversion of closed courts into open terraces; this has been carried out to a comparatively limited extent, for only 90 courts have been opened up by the removal of 152 obstructing buildings; but the results have been so successful from the point of view of the health and habits of the occupants that this part of the scheme is to be extended. At present it is the intention of the committee to commence in the centre of the city and to work outwards towards the suburbs in all directions so that the results may become obvious from all sides. The work is so obviously advantageous to everyone that, as a rule, it has secured the support of the property owners affected and the cost to the city is lessened by taking the improvement of the value of the property into consideration in estimating the compensation which must be paid in certain cases. So far the cost has been £5047, and in the estimates for the current year £3500 are provided for the compensation which will probably be necessary in association with the more extensive plan of work.

The Birmingham Medical Benefit Society.

The annual report of this society shows a sound financial position and a record of helpful work which might be greatly increased if the members of the medical profession in the district would become members of the society in greater numbers. The objects of the society are to help poorer members of the profession and, in the event of their deaths, their widows and children. At present the society, according to the authority of Sir James Sawyer, has 400 members out of 4000 medical men of the district who are eligible; nevertheless, as Dr. E. M. Whitcombe, the President, pointed out, it possesses invested and other funds to the amount of £16,000 and it provided in grants last year the sum of £763.

of the frontal sinus. Enlargement of the sella turcica had been demonstrated with the rays in cases of acromegaly. Odontology owed much to them and diseases of the thorax were often elucidated by a good x ray photograph, especially if there were enlarged intrathoracic glands or an aneurysm causing compression of nerves or displacement of the heart or the trachea.

Professor KILLIAN (Freiburg) showed a series of fine X Ray Photographs in which the topography of the accessory sinuses could be studied at leisure. After explaining the method of taking these photographs he said that not only the size of a sinus but also its position, its relations to other parts of the head, and the condition of its mucous membrane could be learned from the photographs. The information obtainable in this way was especially valuable before the performance of an operation on the ethmoidal or frontal sinus. In taking those photographs Professor Killian always passed the rays in a sagittal direction so that both halves of the head were shown on the same plate. He used "soft" tubes and an exposure varying from one to three minutes.

Professor GRADENIGO (Turin) read a paper on the Therapeutic Value of the Rays and Radium in Diseases of the Upper Air Passages. In enumerating the advantages of this method of treatment he said that the resulting scars were very flat and little noticeable, while the treatment itself was not only painless but free from danger in experienced hands. The disadvantages were that little effect was produced in the depth of the tissues, that there was a possibility of the spread of malignant disease under a healthy looking scar, and that recurrence was frequent. Good results had been obtained in cases of lupus and epithelioma but not in sarcomata. Radium could be used in the interior of small cavities but in lupus of the mucous membranes of the nose and the mouth or larynx it was not so efficacious as in lupus of the skin.

Relations between the Nasal Sinuses and the Eye.

Professor KUHNT (Bonn) spoke on the Correlation between the *Anterior Accessory Nasal Sinus and the Eye* and drew attention to the existence of a sympathetic connexion between inflammations of the ethmoidal labyrinth and diseases of the lacrymal apparatus, such as dacryocystitis or conjunctivitis; panophthalmitis had also been observed as a sequel of acute empyema of the frontal sinus. It was necessary to be cautious in tracing a connexion between nasal conditions and symptoms dependent on diseases of the bulbar nerves, such as muscular paralysis or optic neuritis, because the pathological anatomy of those cases was not quite clear.

In the discussion following the paper Dr. RÉTHI (Vienna) said that in two cases under his care impending blindness was averted by clearing out the ethmoidal cells, after which rapid recovery of sight took place. Several reports from Professor Chiari's clinic also showed that recovery of sight had undoubtedly followed intranasal operations.

Malignant Disease of the Larynx.

Professor MOURE (Bordeaux) read a paper on the Operative Treatment of Malignant Disease of the Larynx. He advised the performance of a radical operation with simultaneous tracheotomy and was in favour of uniting the tracheal and laryngeal incisions into one large wound. In order to prevent pressure on the tracheal rings he had had a tracheal tube constructed in very thin aluminium, thus reducing pressure to a minimum.

Professor LENDZIAK (Warsaw) communicated a paper entitled "The Radical Procedure for Malignant Disease of the Larynx in the last 50 Years." The author not being present only an abstract of it was read. In a historical review which he gave of the positions of different surgeons in reference to this question he said that the first in this field was Billroth who in 1873 removed a carcinomatous larynx with good result, and since that date total or partial laryngectomies had been performed nearly every year. The general discussion on this subject at the International Congress held in London in 1887 promoted the knowledge of the surgical methods in a high degree. Endolaryngeal methods were chiefly advocated by Fränkel of Berlin, and in Sir Felix Semon's hands "laryngo-fissure" had given the most brilliant results—namely, 80 per cent. of recoveries lasting from four to eight years. Partial or total resection of the larynx had been chiefly practised in Germany, where von Bergmann and Gluck obtained recoveries which continued for periods of from five to 11 years. Professor Lendziak had studied the records of 1002 cases of carcinoma of the larynx occurring in all countries and operated on by all methods. He found that the results had improved considerably since 1888. Laryngo-fissure gave the best results (50 per cent. cures) if used early enough; recurrence was best prevented by total extirpation, whilst mortality was highest by the last-named method. Therefore laryngo-fissure was the safest method. As long as cancer was a local disease it could be cured by local measures.

Dr. IMHOFER (Prague) read a paper entitled

"*The Knowledge of Tuberculosis of the Larynx by the Ancient Greeks and Romans.*"

He showed that Hippocrates and Celsus distinguished this condition from others and used dietetic treatment. Galen was the first to recognise it as an ulcerating condition and ordered his patients to take certain liquids whilst lying on their backs, so as to allow of the liquid entering the larynx. It was interesting to note that Dr. Heryng of Warsaw quite recently rediscovered this method.

Professor JURASZ (Heidelberg) read a report entitled

International Laryngo-Rhinological Congresses.

This gave rise to a discussion on the advisability of holding another congress, and it was decided to form an international committee which should decide where and when the next congress should take place. Sir Felix Semon was selected to represent England on the committee which will consist of six members.

Dr. VOHSEN (Frankfort) described his method of transillumination of the accessory sinuses and demonstrated it practically on several persons. He advised it especially for the frontal sinus. The conditions necessary to success were the use of a very small instrument, good regulation of the light, absolute darkness of the room, and application on the floor of the sinus. It was essential to remember that previous inflammations left behind them thickenings or other changes of the mucous membranes, so that the definition of the pictures was somewhat altered by them. The transillumination of the antrum of Highmore also gave good results, but for differential diagnosis it was not quite safe as cysts or thickened walls might give the same appearances as accumulations of pus.

The time occupied by the reading of papers and the discussions having been longer than was expected a good many papers had to be mentioned only by their titles. As a social meeting the Congress was a complete success. Not only were the members invited to a banquet by the city of Vienna but even the Governor of Lower Austria, who represented the Protector (the Heir Apparent), held a grand reception in their honour. At the banquet given by the city the magnificence of the town hall was well displayed, whilst at the reception in the stately old renaissance palace of the Governor there was a brilliant assembly of scientific men, titled personages, diplomatists, and eminent State dignitaries. A special entertainment committee for the lady visitors was formed by the ladies of the general committee of the Congress, the items of their programme including a variety of excursions and theatrical performances. In connexion with the Congress there was an exhibition of objects relating to laryngo-rhinology, œsophagoscopy, and bronchoscopy. It included instruments for examination, operation, treatment, and illumination, as well as numerous manuscripts of historical value, books, anatomical and pathological preparations and illustrations which belonged to Türck and Czermak, the first laryngoscopes used by them, and the first collection of clinical pictures of laryngological cases. Many pictures and specimens from the Vienna Laryngological Clinic were also on view, while Dr. Onodi, Dr. Hennig, and many foreign physicians contributed numerous objects of interest.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Port Sanitary Authority: Annual Report of the Medical Officer of Health.

THE annual report of the medical officer of health to the port sanitary authority contains many interesting statements. The regulations for the examination of vessels arriving in England from foreign ports are very similar to those in force since 1896, with the exception that the definitions of the terms "infected" and "suspected" ship have been modified.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Aberdeen Royal Infirmary: Great Donation from Lord Mount-Stephen.

A SPECIAL meeting of the directors of the Aberdeen Royal Infirmary was held on May 29th. The chairman informed the board that he had received from New York a bank draft for £26,758 6*s.* 3*d.* sent to him by direction of Lord Mount-Stephen. In a letter dated May 27th his lordship explained that the above-mentioned amount was the proceeds of railway stock which he at first proposed to transfer to the Royal Infirmary as an addition to its investment fund. Lord Mount-Stephen proceeds to say: "Since I had the pleasure of seeing you in London and hearing what you had to say about the position of the infirmary I came to the conclusion that the best use that could be made of my gift was to spend it exclusively on the permanent improvement of the hospital, rather than in providing for an increase of income. What I mean by 'permanent improvement' is expressed by the directors in their last annual report where they state that 'the most urgent necessities of the hospital will require a sum of at least £25,000.' Let me say in conclusion that I should consider it but little short of a calamity, if what I have done for the hospital should have the effect of weakening the interest of the people of Aberdeen in the old infirmary in which I was a patient 63 years ago." The board expressed its feeling of most grateful appreciation of Lord Mount-Stephen's continued goodness to the infirmary, a feeling which the board was sure was shared not only by the citizens of Aberdeen but also by the whole population of the wide district benefited by the infirmary and it thanked his lordship cordially for his munificent and most opportune gift.

University of Edinburgh: Retirement of Professor Crum Brown.

For some time past it has been rumoured that Professor A. Crum Brown, professor of chemistry in the University of Edinburgh, proposed to retire from his University duties. The rumour has passed into accomplished fact, for his resignation has been accepted by the University Court. All the men who occupied the medical chairs in Edinburgh in the early "seventies" have now passed from them. Professor Crum-Brown was the only one remaining after Sir A. R. Simpson resigned. Sir William Turner is the only one who by becoming Principal on resigning his chair retained his University connexion. Professor Crum Brown has occupied the chair for 39 years. Coming early in the medical curriculum as chemistry does, it has been a very large class and a class that is a great strain on a teacher in many ways.

A New Chair.

An important step in the equipment of scientific education has been taken in the endowment and constitution of a chair of pathology and bacteriology in the Royal Veterinary College, Edinburgh. This has been made possible by the munificent gift of £15,000 by Mr. A. I. MacCallum, J.P., M.R.C.V.S., himself an old student of the College. At a recent meeting of the board of management Dr. Gerald R. Leighton, who has taught these subjects in the College for the past six years, was unanimously appointed to the chair. Dr. Leighton's best-known works deal with British reptiles from the field naturalist's point of view, but he has been a voluminous writer on many phases of animal life. He is M.D. of the University of Edinburgh and a Fellow of the Royal Society of Edinburgh.

The Inspection of Meat in Scotland.

For some time past the subject of the inspection of meat has been prominently before the public health authorities. Largely owing to the efforts made in the matter by the corporation of Glasgow an inquiry into the whole question of meat inspection in Scotland was ordered by the Local Government Board and conducted by its medical inspector, Dr. F. Dittmar. The result of this inquiry is embodied in a report just issued. In this it is stated that while cattle are generally killed in licensed slaughter-houses and are thus subject to a certain measure of inspection, it would appear that pigs destined to be cured for the production of ham and bacon are almost wholly killed at the place of feeding—*i.e.*, at farms, &c. The reason given by the trade for this custom is that "driven pork" does not cure well. The result is that these carcasses are not examined by the public health officials and any kind of diseased carcass may be dressed and cured and put on sale. A notable difference as to the prevalence of tuberculosis in pigs emerges in this report. In Glasgow during 1906 of 45,456 pigs slaughtered 3040, or 6·68 per cent., were found affected with tuberculosis. In Edinburgh, of 6175 slaughtered only one, or 0·016 per cent., was affected, while in Dundee only 0·60 per cent. were affected. The explanation given in Edinburgh and Dundee for this very striking difference is that pigs in the East of Scotland are fed only to a slight extent on milk or milk products, the food being mainly hotel or boarding-house scraps, while in the West of Scotland the pigs are said to be largely "dairy fed." Dr. Dittmar, however, finds it difficult to believe that the character of the food accounts for the great difference in the extent to which tuberculosis is present in pigs slaughtered in Glasgow, Edinburgh, and Dundee. He thinks there can be little doubt that difference in the method of examination practised in each abattoir will account to a large extent for the differences noted. As regards the methods of inspection the report states that in Edinburgh it appears to be efficient, but it goes on to say that in Glasgow the examination of each carcass, &c., is more searching and carried out in greater detail than in any other abattoir visited in Scotland. Dr. Dittmar then proceeds to suggest some points in which an improvement on existing conditions could be made. 1. Subject to certain exceptions it should be made illegal to slaughter any animal intended to be sold for human food in any but a duly licensed place. 2. The Local Government Board should be empowered to call upon burghal local authorities to provide public slaughter-houses, and that with a view to increasing the revenue of the slaughter-house, and thereby providing funds for more efficient management, in burghs of less than 6000 inhabitants no slaughter-houses other than public ones should be allowed within a radius of five miles of the burgh boundary; also, that where a slaughter-house is provided by a landward local authority all private slaughter-houses within a defined distance of the public one should cease to exist, and that power should be given to burghal and landward authorities to combine for the purpose of erecting a common slaughter-house. 3. That persons licensed and paid by the local authority should be appointed in landward districts whose duty it would be to kill animals intended to be sold for human food. 4. That meat inspectors and superintendents of slaughter-houses should possess certificates of competency in the work from some recognised examining body. 5. That recommendations for the guidance of meat inspectors in condemning carcasses might be issued. 6. That inspection by competent officers of all animals at the time and place of slaughter should be aimed at, that arrangements should be made whereby consignments of dead meat coming to a town should be inspected before being put on sale, and that the Government of this country should be satisfied of the thoroughness of inspection at the time and place of slaughter before meat is exported to this country. 7. That the Local Government Board should call for certain returns of the number of animals slaughtered yearly in public slaughter-houses.

The Medical Officership of Health of Edinburgh.

Owing to the retirement of Sir Henry D. Littlejohn the city of Edinburgh has to appoint a medical officer of health. There is already a rich field of candidates to select from—at least 12 well-known names are given. The salary is stated to be £800 per annum.

Clinical Research.

Through the medium of Dr. G. A. Gibson a gentleman, who meanwhile withholds his name, is desirous of establishing a laboratory for clinical research in connexion with the Edinburgh Royal Infirmary. A meeting of physicians to the infirmary has been called by Dr. Gibson to consider the matter and to see what steps it may be advisable to take and what form the scheme can take.

June 2nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Annual Meeting of the Royal College of Surgeons in Ireland.

THE annual general meeting of the Fellows of the Royal College of Surgeons in Ireland was held on May 30th. The annual report of the Council was received

Dr. H. Malet of Wolverhampton was made President for the ensuing year and Sir Thomas Chavasse was appointed President-elect.

A Result of Medical Inspection.

At a recent meeting of the Bilston education committee it was stated that it had been found necessary in some cases to follow up the inspection with nursing, and a motion was adopted requesting the urban district council to appoint a nurse jointly under the Notification of Births Act, 1907, and the Education Act, 1907.

Hospital Saturday Collections.

The annual collection was made in the various works of West Bromwich last Saturday and the total result reported on Monday last was £776. Last year the total was £933, and that amount may possibly be surpassed this year, for at the time stated several of the large works had not reported their contributions. The collection is made on behalf of the West Bromwich and District Hospital. At Oldbury the collection on Saturday reached the sum of £388, or £100 more than the amount at the same period last year.

Increased Birth-rates.

The fall of birth-rates is so common that it is interesting to note two increases in this district. At Yardley Dr. G. Wilson states in his annual report that the rate rose during the past year from 25·9 to 26·7 per 1000, and at Dudley Mr. J. H. Wilkinson reports that it increased from 29·73 to 31·34 per 1000. At Yardley during the same period the death-rate fell from 12·6 to 11·3 per 1000 and at Dudley it was 17·3 per 1000, a little more than in the previous year.

June 2nd.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Sanatorium Treatment in Newport.

THE Newport (Mon.) board of guardians has for some time treated the consumptive patients under its care in a building which is quite distinct from the workhouse and the results have been very satisfactory. During the past few months the corporation has had under treatment at the isolation hospital persons of the non-pauper class suffering from pulmonary tuberculosis. A large wooden hut was erected in the grounds of the hospital at a total cost, including furniture, of £1000. There is accommodation for 14 patients but for the present it is being occupied by six, as it is anticipated that the maintenance of this number will absorb the £350 per annum which have been allocated for the purpose by the corporation. Patients are admitted for one month with the object of giving them the benefit of a training in the methods adopted in the open air treatment and of training them in respect to the precautions necessary to prevent them from infecting their friends and reinfecting themselves. No charge is made to the patients, who must, however, be necessarily residents in the town of Newport. The medical officer of health (Dr. J. Howard-Jones), upon whose recommendation the scheme was adopted, is hopeful that it will result not only in a reduction in the prevalence of the disease in the borough but will also place patients on the road to recovery.

A Clean Milk Supply.

At a sessional meeting of the Royal Sanitary Institute held at Shrewsbury on May 23rd a discussion upon the inspection of dairies and cowsheds was introduced by Mr. T. W. H. Garstang, medical officer of health of several rural districts in Cheshire. Dr. James Wheatley, medical officer of health of Shropshire, discussed the possibility of keeping cattle in the open air for the whole year and gave an interesting account of some experiments which have been made in recent years at the Harper-Adams Agricultural College in Shropshire with a view of ascertaining the effect upon cattle of leading a completely open-air life. Two lots of cows were selected as closely alike as possible. One lot was brought into the sheds each night commencing at the beginning of November, and the other lot was kept out until the beginning of December. Taking the average results the cows that were kept out all night gave more and richer milk and gained more in weight than those that were brought in. The results for the four years during which the experiments were conducted were decidedly in favour of leaving the animals out during the night. Observations made during very cold nights found the animals lying close to the homestead. No shelters were available, but the animals did not appear to seek shelter from the hedges. Dr. Wheatley expressed the opinion that these experiments entirely disposed of the tradition among farmers that warm and therefore ill-ventilated cowsheds were necessary for the free production of milk. The difficulties attending the application of this open-air system were pointed out by the Principal of the Harper-Adams College; they were difficulties of management and ought not to be insuperable. The principal drawback was the irregular distribution of the manure. The cows left it for the most part in the sheltered spots, around hedges and near gateways. The surface of the land, too, in a wet season became trodden down, to the detriment of the herbage in the following summer. If these difficulties could be overcome the problem of a clean milk-supply would be very nearly solved.

The Midwives Act at Cardiff.

At a meeting of the Cardiff health committee held on May 26th, the medical officer of health reported upon the alleged negligence of a midwife. It was decided to report the case to the Central Midwives Board and on the suggestion of the chairman, Mr. J. Robinson, it was decided that a medical man should give brief lectures once weekly on the subject of midwifery for the benefit of those midwives who were registered but had not passed any examinations.

Bristol Poor-law Infirmary.

The attention of the Bristol board of guardians has once more been drawn to the unsatisfactory arrangements that are made for the sick and old or infirm paupers at the Eastville workhouse. In a report by Mr. E. B. Wethered, one of the Poor-law inspectors of the Local Government Board, the danger in the event of fire of still using wooden huts for the accommodation of patients is very forcibly pointed out. There are two such huts, each containing 40 beds, occupied by men, and two with 20 beds in each for women. There are many helpless persons in these buildings the retention of which throws a very great responsibility upon the board of guardians. For more than ten years the question of providing adequate accommodation at this workhouse has been under discussion and a few years ago plans for suitable buildings were actually prepared and approved, but chiefly on the score of expense the work was not proceeded with. A policy of inaction is now being advocated by a majority of the members of the board of guardians, first of all on the plea that the report of the Royal Commission on the Poor Laws may recommend drastic changes in their administration, and, secondly, on account of the adoption by the Government of the principle of old-age pensions. In the meantime the principal officials at the Eastville workhouse must be having a very anxious time.

Bristol and West of England University.

The near prospect of securing a University for Bristol and the West of England being now assured it is proposed to endow a chair of Anatomy in the new University to perpetuate the memory of the late Dr. Edward Markham Skerritt who for several years rendered distinguished services to the Faculty of Medicine of University College, Bristol, both as dean and professor of medicine. An appeal has been issued for subscriptions, which may be sent to the treasurer, Markham Skerritt Memorial Fund, Faculty of Medicine, University College, Bristol.

University College, Bristol.

The Council of University College, Bristol, has appointed Mr. Cyril Hutchinson Walker, B.A., M.B. Cantab., F.R.C.S. Eng., ophthalmic surgeon to the Bristol General Hospital, to the post of additional lecturer on ophthalmology in the Faculty of Medicine of the College.

A Medical County Councillor.

Mr. Rees Thomas Edward Davies, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., J.P., was on May 25th elected representative for Bedwellty West on the Monmouthshire county council.

(FROM OUR OWN CORRESPONDENT.)

The Administration of Antidysenteric Vaccines by the Mouth.

AT the Biological Society on May 16th M. Dopter recorded some experiments on the vaccination of fully grown mice by feeding them with bacilli of dysentery of the Shiga type, both living and dead. For this purpose he weighed out 0·005 milligramme of these bacilli, obtained by scraping an agar culture in a Roux's chamber, and having killed them by submitting them to a temperature of 60° C. for an hour he dried them in a vacuum. He made an emulsion of the bacilli in milk and fed the mice with them for three days running and this process was found to confer immunity. The subcutaneous inoculation of one or even two ordinarily fatal doses of living bacilli in the animals thus treated from 12 to 15 days afterwards did not kill them, whilst control animals died in three or four days. His experiments showed that one single ingestion of this dose is insufficient to bring about immunisation, and that it is only conferred with weaker doses when they are repeated daily for a week. The immunity is not complete until about the end of 12 days and it usually lasts for a month. From the first to the twelfth days, whilst the state of immunisation is in process of development, a "negative phase" is induced, and the animal is more sensitive than the control mice to an ordinary fatal dose. Similar results were obtained with living bacilli; with these the optimum dose corresponds to the amount of emulsion obtained by scraping the culture from one agar tube after 24 hours' growth, and this dose should be repeated in a few days.

Syphilis and Myopia.

M. Antonelli has communicated a paper on this subject at a meeting of the French Ophthalmological Society. He said that syphilis may be the sole cause of myopia, it may aggravate it, or it may complicate it. The first proposition is illustrated by congenital syphilis, for a number of persons afflicted with that malady are myopic from early childhood or become so as the result of such disorders as interstitial keratitis. This congenital, or at least infantile, myopia of the subjects of hereditary syphilis is sometimes monocular; it is often unequal in the two eyes and may occur in combination with dystrophies of the ocular membranes and lesions of the fundus. Acquired syphilis shows itself rather by aggravating and complicating myopia in patients who already have it more or less strongly marked and who are in a state of general bad health. With regard to the complications there is no doubt that myopic eyes are predisposed to the later manifestations of syphilis. Chorio-retinitis with damage to the papilla, macular or intra-vitreous hæmorrhages, exudative troubles of the vitreous, and retinal detachment occur most frequently in myopes of old standing, who have become tainted with syphilis, and it is easier to prevent these complications by energetic and prolonged mercurial treatment than it is to cure them.

The Re-education of the Muscles in the Treatment of Different Palsies.

The general term of muscular re-education covers a series of very different procedures which must not be confounded with each other. The treatment of ataxia, paraplegia, hemiplegia, and spasmodic paralysis requires different methods for each. Passive movement and the long-continued training in voluntary movements combined in various manners have given rise to several methods, of which certain ones, such as the treatment of ataxia, are widely known and appreciated. M. Faure brought the question before the Medical Society of Paris on May 8th and pointed out that others, such as the treatment of spasmodic palsies, are less generally recognised. The educative treatment of hemiplegia gives appreciable results, but less striking than when it was applied to cases of ataxia. These methods demand the expenditure of much time and patience and must be carried out with the utmost precision.

The Thermic Effects of High-frequency Currents on the Body.

At the Academy of Sciences on May 11th M. Zimmern and M. Turchini dealt with this subject. Tracings of arterial blood pressure made on the dog show that this pressure is not affected by high-frequency currents. In man it sometimes produces a slight drop of one or two centimetres, but volumetric variations of the pulse, which indicate vaso-dilatation, are more frequent results. An animal under the influence of these currents shows a rise of temperature of several tenths of a degree. Dogs whose temperature is falling progressively under the action of chloral show a similar increase which depends upon the calorific effects of the current, and the dog seeks to counteract these effects by rapid breathing. In the same way a man whose temperature has been thus raised several tenths of a degree attempts to counteract the access of heat by peripheral vaso-dilatation. The increase in temperature is not always sufficient to induce sweating. It would thus seem that high-frequency currents fulfil a want in affording a method of increasing the body heat without expense to the organism, and in this way they form a new procedure in thermo-therapy, more gentle than those already in use but with similar indications for employment. Indirectly, by the vaso-dilatation which it causes, it is a useful adjuvant in dealing with renal congestion and visceral neuralgia, and this action explains the good effects which it has upon the obscure pains experienced in Bright's disease and arterio-sclerosis.

Tuberculous Rheumatism.

At a meeting of the Paris Medical Society held on May 23rd Professor Antonin Poncet, in resuming a discussion on Tuberculous Rheumatism, described investigations which he had made on this condition and on inflammatory tuberculosis. M. Dupuy de Frenelle recommended general treatment for the tuberculosis; hyperæmia, *effleurage*, and massage for the limb; and very cautious movement alternating with periods of rest for the joint. He did not think that the effects produced by ankylosing tuberculous rheumatism were so obstinate and so difficult to treat as Professor Poncet supposed.

Diagnosis of Cancer by a Specific Reaction with Micrococcus Neoformans.

M. Doyen, in a communication to the Biological Society, has stated that the blood serum of cancerous people contains specific bodies which possess a selective action upon an extract of powdered tumour cells and micrococcus neoformans and upon young cultures of that organism which results in fixation of the complement or in agglutination. The diagnosis of obscure cases of cancer may perhaps be best determined by a combination of three investigations—namely, the power of fixation of the complement, of agglutination, and the determination of the opsonic index.

June 2nd.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

International Conference on Cancer.

ON the occasion of the opening of the Cancer Institute in Heidelberg in October, 1906, an International Conference on Cancer was held in that city and in Frankfort. The success of that conference has induced the committees of different States to found an International Union for Cancer Research which met for the first time in Berlin on May 23rd under the presidency of Professor von Leyden. 13 States were represented, including Germany, Austria, Hungary, France, Russia, Denmark, the United States, and Japan, but England was not represented. The seat of the union will be Berlin. The aim of the union is to support institutions for cancer research and treatment; to compile international statistics concerning cancer; to establish an international bureau for the coördination of cancer research, and to edit an international journal on cancer. Professor von Leyden was elected honorary president, Professor Czerny of Heidelberg president, and Professor Marie of Paris and Professor Fibiger of Copenhagen vice-presidents. The third vice-president will be an American, to be elected by the American national committee. Professor Hansemann of Berlin will act as treasurer and Professor Meyer of Berlin as general secretary. The other members of the committee are Professor Podwyssowski of St. Petersburg, Professor von Hochenegg of Vienna, and Professor Golgi of Pavia. The first meeting of the union was held in the great lecture hall of the Pathological Institute; representatives were present of the Government, the University, the Army and Navy Medical Corps, and of the Medical Association of Berlin. Addresses of welcome were delivered by the Minister of Public Instruction, the Rector of the University, and by and adopted unanimously, after which a discussion took place on the Irish Universities Bill in regard to its effect on the future of the College. The opinions arrived at are well set out in the following motion, which was proposed by Sir Charles A. Cameron, C.B., ex-President, professor of chemistry and of hygiene (and historian) of the Royal College of Surgeons in Ireland; seconded by Mr. J. S. McArdle, ex-President of the Irish Medical Association and professor of surgery, Catholic University Medical School; and unanimously carried by the meeting:—

> That this College, while in no way desiring to interfere in the question of University education, views with alarm the consequence to the College which will be brought about by the establishment, under the Irish Universities Bill now in Parliament, of a State-endowed medical school in connexion with the proposed new University in Dublin, for it is to be anticipated that serious damage and loss will result to the unendowed school of this College and, therefore, to the Royal College itself, from that State-aided competition.
>
> That it is contrary not only to justice and fair-play, but also to the public interest, that this College, established by Royal Charter, and its school, which for a century and a quarter have done great and important work for the State and the country, and which, if permitted, would be competent to continue that valuable work, should be crushed.
>
> That the College approves of the steps taken by the Council to bring its claim for a Government grant for its school to the notice of the Chief Secretary, and it hereby expresses its belief in the justice of that claim, and presses it on the favourable consideration of the Government.

Sir Lambert H. Ormsby supported the motion, recalling that the crisis had now arrived in the history of the College, of which he had foreshadowed the possibility in his own presidential address at the corresponding annual meeting of June, 1904, and spoke with conviction as to the danger to the medical school attached to the College, and in due course to the College itself, which had conferred, he said, "such lasting benefit on the general public by insuring that every year highly educated and fully qualified Fellows and Licentiates received their diplomas to practise surgery in Ireland and different parts of the world, while during the long period of its existence as a licensing body its paramount aim had been high culture and efficiency, unbiassed by political or sectarian influence of any kind." Mr. John Lentaigne, now President of the College, dwelt eloquently, as a Roman Catholic, on the religious liberality displayed by the College; and the audience were distinctly impressed with the fact that the issue ahead of the College is a very serious one.

The Election of Officers at the Royal College of Surgeons in Ireland.

The annual election of President, Vice-President, Council, and secretary of the Royal College of Surgeons in Ireland was held on Monday, June 1st. For the presidency, vice-presidency, and secretaryship the election was in each case unopposed, but the contest for seats on the Council was actively carried out. A total number of 268 votes was recorded; three were returned by too-late posts and five were "spoilt in the making." The following were elected and I have appended the number of votes recorded for each:—(President, John Lentaigne; Vice-President, Robert H. Woods; secretary, Sir Charles A. Cameron) Sir Henry R. Swanzy, 229; William Stoker, 162; Sir Charles Cameron, 238; Sir Lambert Hepenstal Ormsby, 180; Richard D. Purefoy, 190; Henry Gregg Sherlock, 185; Sir Charles B. Ball, 204; John B. Story, 208; Edgar D. Flinn, 161; Sir Thomas Myles, 216; Sir Arthur Chance, 210; Richard Lane Joynt, 176; R. Bolton McCausland, 168; Thomas E. Gordon, 175; Edward Henry Taylor, 201; G. Jameson Johnston, 176; William Taylor, 193; R. Charles B. Maunsell, 175; and William Ireland Wheeler, 195. Two members of the past year's Council have lost their seats, Dr. Thomas Donnelly, the active secretary of the Irish Medical Association, and Mr. J. S. McArdle, who has announced his candidature in the usual official way for the vice-presidency of the College in 1910–1912. Mr. J. B. Story has done the same.

Cerebro-spinal Meningitis.

Several cases of "spotted fever" have occurred in the Lurgan district. Two deaths have taken place in the Lurgan workhouse fever hospital within the week ended May 27th.

The Report of the Belfast Health Commission.

At a meeting of the Belfast water commissioners held on May 28th reference was made to the difficulty experienced in obtaining copies of the report of the Belfast Health Commission. It appears that the Local Government Board thought it right to issue the report in the first instance to the corporation of Belfast and to allow an interval to elapse before sending copies to the press. These copies were despatched on April 24th and on that date a copy was also forwarded to the secretary of the water commissioners. The chief clerk of the corporation has since sent three copies. As the question of the water-supply was specially under consideration, and as £2000 were spent by the commissioners in getting up evidence, naturally they are annoyed that they cannot—even by paying for it—procure a copy of the report, and as one of them said at the meeting, "How otherwise could the commissioners be in a position to comply with the recommendations made." In reply to a question in the House of Commons on May 28th the Chief Secretary said that 250 copies of the report were printed at the expense of the Belfast corporation and of these the Local Government Board had 150, nearly all of which had been distributed amongst public bodies and interested parties. The corporation has declined to incur the expense of printing additional copies and the Chief Secretary had no power to compel it to do so. As, however, the Chief Secretary said the report is of general interest he would lay it on the table at an early date.

Consumption in Belfast.

The Local Government Board has approved of an arrangement by which, as proposed by the Belfast city council, ten further beds in the Forster Green Hospital will be allocated for the use of consumptive patients nominated by the public health committee of the corporation.

The Irish Medical Association.

The annual general meeting and conference of this association will be opened in the Royal College of Surgeons, Dublin, on June 10th. The annual dinner will take place on the same evening, and on the next day the President-elect (Sir William J. Smyly) will give a garden party in the Zoological Gardens, Phœnix Park. The third day (Friday) is to be devoted to an excursion at Glendalough. From the sixty-ninth annual report, to be presented, it appears that on Dec. 31st last the association consisted of 726 members. Financially, the income received, with the balance in hand at the close of last account, amounted to £782 and the expenditure to £730, leaving a credit balance of £51.

British Dental Association.

The British Dental Association is to visit Belfast for its annual meeting at Whitsuntide from June 6th to 9th. The opening meeting is to be held on Saturday, June 6th, in Queen's College, Belfast, when an address will be given by the President, Mr. J. J. Andrew, L.D.S., of Belfast. On the previous evening a popular lecture on the Teeth of the People: a National Asset, will be given in the Technical Institute by Mr. L. Matheson, L.D.S., of London, and on Saturday night the annual dinner will be held in the Grand Central Hotel, Belfast.

Bovine Tuberculosis in Belfast.

At a meeting of the Belfast corporation held on June 1st a report was given by the city veterinary surgeon to the effect that of 3452 milch cows examined only one had been affected with tuberculosis, and that of 27,446 cattle slaughtered in the Belfast abattoir in 1908 only 384 were found to be tuberculous, or 1 in 70. Mr. Councillor Gregg, M.R.C.V.S., a member of the public health committee, immediately challenged these figures, and said that until the tuberculin test had been applied it could not be definitely said that cows examined were free from tuberculosis. Mr. Gregg, who is also the honorary secretary of the North of Ireland Veterinary Association, has since this statement was made to the corporation written to the Belfast press showing that only in one case of the suspicious dairy cows could the veterinary surgeon of the corporation prevail on the owners to allow the tuberculin test to be used and in that case a positive reaction was present. It is clear therefore, that there has been some fallacy in the statistics. Under the new Dairies and Cowsheds Order adopted by the corporation the veterinary surgeon will be able to use more freely the tuberculin test. In reference to the reported absence of tuberculosis in such a large number of slaughtered animals Mr. Gregg says that the majority of these were young cattle from the country districts where the disease is not so prevalent as among older milch cows in crowded cities.

June 2nd.

appeal to the medical auditor (who, as stated, was numerously represented in the assembly) to coöperate in the work by giving his invaluable aid in the prompt reporting and due selecting of subjects for the "Scuola" and the "Casa" of Labour alike—subjects who, in the practitioner's judgment, might profit by these institutions and give prestige and support to their beneficial mission.

May 31st.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Professor August Forel on the Tasks of Social Hygiene in the Twentieth Century.

ON the occasion of Professor August Forel's visit to Budapest for the purpose of delivering an address on the Tasks of Social Hygiene in the Twentieth Century the town-hall was selected as the place of meeting and there was a very large attendance. Before presenting the chief points of his discourse I may give some particulars relative to his life and scientific work. He is a tall, grey man, lively in demeanour, and a quick speaker. He was born in the French-speaking part of Switzerland in 1848. He holds the degrees of doctor of medicine and doctor of philosophy. He was formerly assistant at the psychiatric clinic in Vienna, afterwards becoming professor in the University of Zürich, and now he practises his profession in Yvorne, a small village in Switzerland. He has never been wealthy, although enjoying a reputation which brings patients from all parts of the world to seek his advice. The two subjects which have formed the chief pursuits of his life are the treatment of mental diseases and the natural history of ants, the former being his professional occupation, while the latter is his pastime. On the subject of ants he has written one large work, together with more than 100 shorter memoirs in which he has described an immense number of varieties of these insects. As a boy of 16 years he undertook an experiment with a view to ascertain whether the community exists only as long as the mother ant survives. He made an anthill on the yard of his father's house and studied the insects for 10 years. When 30 years of age he became professor and director of a large lunatic asylum in Zürich, but in 1898 he resigned both appointments in consequence of a dispute with the Cantonal Government and entered on private practice. The great success of his first considerable work, "Die Sexuelle Frage" ("The Sexual Question"), is shown by its being translated into French, English, Hungarian, Swedish, Italian, and Spanish. The proceeds of the sale of this book enabled him to buy a house in Yvorne where he lives with his family and with two or three resident patients. Indifferent to the so-called pleasures of life and limiting his personal wants to the mere necessaries of existence, he passes the whole day in mental application and regrets as lost the time which has been otherwise employed. As already mentioned, his audience in the town-hall at Budapest was very large, comprising about 2000 persons, most of whom were medical men. He began his discourse with a survey of the progress and development of mankind during last century, saying that the most notable figure of the nineteenth century was neither Bismarck nor Napoleon but Darwin. He considered that the immense development of industrial undertakings has made the people of the present day very self-conceited. They are inclined to over-estimate their own mental capacity in comparison with the men of olden times and other continents. It cannot be denied that certain races of mankind are superior in brain power to some other races. For instance, mental work like that of the white races could never be expected from negroes. It has, however, been a great mistake on the part of the white races to underestimate the immense progress, both material and intellectual, which the Japanese have made during the last 30 years. Some people say that the Japanese are only imitating us. But did not the European nations in the fifteenth century, the age of the Renaissance, imitate the Greeks and the Romans? And do they not now acknowledge the fact with justifiable pride? There was no difference, he said, between the mental capacity of the ancients and the moderns; the only difference was that we, the moderns, had inherited the experience of our ancestors and the great stock of scientific knowledge which they had accumulated with immense diligence and pains. We have in this way learned a great deal which was unknown to the Greeks and Romans. While over-estimating the triumphs of technics and industry we not only forget the reverence and respect due to the individual, but we lose sight of the great and important question how the human race can be improved and brought nearer to perfection. It is a false estimate of human duty not to prevent the propagation of the race by individuals of imperfect mental and physical development. One of the most important tasks of social hygiene and the medical profession was to prevent degenerates from propagating. It was also necessary to demolish several false gods—first of all, Bacchus and Gambrinus, who were a constant peril to the human race. Alcohol weakened the mental power even of those who took it in strict moderation. To remedy these many miseries of mankind was the task of social ethics, and those who worked in this good cause took for their motto the words, "Let us give more to the community than the community gives to us." The idea embodied in social ethics was self-sacrifice on the part of the individual for the good of the community, whereas sacrificing for one person was a kind of egoism. Women ought especially to beware of it. In some respects the female brain was inferior to the male brain, but in the qualities of mental alertness, sympathy, and perseverance women were decidedly superior to men. Social ethics have for their necessary supplement social hygiene, which aims at producing healthier and happier generations. Both of them aim at the prevention of human misery. Both of them, therefore, denounce alcoholism and the passion for money-making which presses so heavily on the masses and converts the working classes into mere proletarians. Both of them alike inculcate sexual purity and early marriage. Prostitution ought to be abolished by removing its causes and not by vain attempts to enforce repressive police measures. A student, aged 22 years, who loved a girl, aged 18 years, asked Professor Forel to advise him what to do, because some time must elapse before he could marry her on account of his inability to maintain a wife and the child who was to be expected. Professor Forel's advice in such cases is that the lovers should marry but should postpone procreation until their circumstances improve. Unhealthy and degenerate married couples who are for that reason ill adapted to be the parents of the coming race ought in his opinion to postpone procreation indefinitely. To forbid such people to marry would be inhuman, but to encourage them to propagate would be contrary to the interests of posterity. Professor Forel argues that as the earth is already sufficiently peopled now is the time to give preference to quality over quantity in the population. As a means of furthering this object he considers the artificial limitation of births to be justifiable. Suitable instruments for accomplishing such limitation have been devised and the use of them cannot be considered immoral. It would be just as reasonable to assert that it was immoral to wear spectacles which similarly do not belong to the body. Professor Forel is a zealous advocate of the emancipation of women, which he expects to be a leading feature of the twentieth century. Among the lower animals, he said, there is no example of the male making a slave of the female, this system being confined entirely to the human family. Women were justified in claiming the right of voting and it was a matter of astonishment to him that some women were indifferent to the attainment of this right. Finally, he expressed a hope that the time would come when all differences of nationality and language would be smoothed away. He was therefore an ardent supporter of Esperanto, a universal language which would bring the nations nearer to each other in the great work of humanity.

June 1st.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Sudden Death of a Prominent Surgeon in Western Canada.

IN the early morning of April 24th Dr. W. S. England of Winnipeg, Manitoba, died from cerebral hæmorrhage. He was 40 years of age. To not many of Canada's surgeons did success come so early in life as to Dr. England. Born in the province of Quebec 40 years ago he matriculated at McGill University, Montreal, in 1885 and received his degree with first-class honours from the same institution in 1889. After spending a year as interne in the Montreal General Hospital he proceeded to Winnipeg, and that he was made of more

Professor Orth (the successor of Virchow) who mentioned that Virchow's famous book on Tumours was left unfinished and especially in regard to the chapter on Cancer. He informed the meeting that this chapter had been written by the late *savant* but that at the time when it was to be printed new researches on cancer were published by Professor Waldeyer and Professor Thiersch in which Virchow's views were corrected. He agreed fully that his views must be revised but he had no time to rewrite the chapter on Cancer and therefore preferred to let his work appear in an unfinished state. The speaker said that if Virchow had witnessed the new experimental era of cancer research he would have undoubtedly brought his views into accordance with the new researches.

The first scientific paper was read by Professor Borrel of the Pasteur Institute of Paris on the problem of the etiology of cancer. He gave a historical survey of the views on cancer, saying that the question had gradually developed from a metaphysical problem to a matter of experiment. Alluding to the work of Ehrlich, Jensen, Bashford, and others, he pointed out the great importance of the discovery that cancer may be transplanted from one animal to another and that sarcoma may in the course of the implantations develop. It is stated that in cancer the normal cells become transformed and that at the same time they acquire the faculty of multiplying in an abnormal degree. The cause of the transformation and of the multiplication is, however, not yet ascertained; it is probable that they are produced by a certain virus, but all efforts to identify it have hitherto ended in failure. Professor Dollinger of Budapest then spoke on some results of the Hungarian statistics on cancer. He drew attention to the fact that in cancer the number of deaths is three times greater than the number of patients who had been under the care of medical men. It must thus be concluded that many of the patients are not aware of their disease or that they suffer so little that they do not require medical attendance. He then mentioned that in Hungary the number of cases of cancer in the country is only one-third of the number observed in towns and he gave a report of the frequency of cancer in the different organs. He concluded from the statistical tables that cases of cancer in which diagnosis and operation have been early have a lower death-rate than others.

Professor Jensen of Copenhagen discussed some problems of experimental cancer research, including researches on growths in larger animals and the causes of the alteration of the histology of cancer after the growth had been conveyed from one mouse to another. The cause may be in a peculiarity of the tissue of the second animal, in the internal qualities of the growth, or in a kind of pure culture produced by the frequent transplantations. Further problems were the action of different rays on cancer, the eventual discovery of an antiserum, and immunity. The fact that a certain species of mouse which was very much disposed to cancer in Frankfort became exempt in Norway leads to the conclusion that the climate, the alteration of food, &c., might be of importance. Experiments must further be made regarding heredity but 100,000 animals and coöperation amongst the different laboratories would be necessary for these investigations. The last paper was read by Professor Podwyssowski of St. Petersburg who spoke on the theory of irritants. He said that the irritation theory was one of the oldest theories to account for the development of cancer. As the result of recent researches it had been stated that certain irritants had an influence on the structure and the chemical composition of cells, so that they were right to suppose that those irritants might influence the development of cancer also as suggested by the late Professor Virchow.

June 1st.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Italian Association for the Advancement of Science: Its Second Meeting.

THE "*Congresso* Italiano per il Progresso delle Scienze"—an "association" organised on the lines of the "British" and, after two abortive attempts within the last 60 years, successfully inaugurated at Parma last autumn—will hold its second meeting from Oct. 18th to 25th in Florence—time and place being *motivé* by the fact that about that date the third centenary of Evangelista Torricelli will be celebrated in the "City of Flowers," associated as she is with the best and latest work of that master in physics, theoretical and applied. An honorary committee, the President of which is His Royal Highness the Count of Turin and the *personnel* of which includes the first names in science, literature, and fine art, as well as distinguished members of both Houses of Parliament, has held its inaugural meeting in the Palazzo Vecchio (Town Hall) of Florence, at which the arrangements for the due carrying out of the programme of the association were the subject of harmonious conference. The municipality will lead off with a reception of the "Congressisti" in the Palazzo Vecchio, while the "Deputazione Provinciale" will not be behindhand in similar hospitalities held in the Palazzo Riccardi. The halls of the Leonardo da Vinci will also be placed at the service of the association. The city and commune will liberally subsidise the "war-chest" of the meeting and the Government is expected to contribute towards the funds already announced *ad hoc*. The working committee or "comitato scientifico" will have as President the Senator Vito Volterra, professor of applied mathematics in the University of Rome, and as Vice-Presidents a body of *savants* in which the medical calling is largely represented to preside over the sections and sub-sections in which the work of the association will be carried out. That work will be classified under three main catagories: (1) that of the mathematical, physical, and chemical sciences; (2) that of the biological sciences; and (3) that of the moral or humanistic sciences. These again will be subdivided into sections and sub-sections to be determined "a seconda delle opportunita di tempo e di luogo" (according as time and place may indicate), to be announced, moreover, at a convenient date. No effort will be spared to improve upon the success already achieved at Parma and to make the last fortnight of October next a memorable one for Florence and for those of the outer world who find attraction in science as well as in history and art.

The Cripple and the Maimed.

On May 29th Dr. Riccardo Galeazzi, professor of orthopædia and privat-docent in clinical surgery in the University of Turin, also Director of the Institution for the Care and Cure of Rachitis in Milan, gave in the latter city a lecture on the schools and workhouses for the cripple and the maimed. His audience was a distinguished as well as a numerous one, many practitioners of medicine and surgery, general and consultant, being in attendance. After an eloquent tribute to Dr. Pietro Panzieri, Italy's apostle in the relief and reclamation of the physically deformed, Professor Galeazzi stated that the proportion of "storpi e mutilati" (cripple and maimed) in society as a whole is 1 per 1000 of the population, while Italy has no fewer than 175,000, of whom 116,000 live in the most squalid misery. To come to the rescue of such Germany has 33 "*schools of labour*" (workhouses) with 2660 pupils, while Denmark, Sweden, and Norway are at the head of the movement, other nations having few such institutions or none at all. America, he remarked, is showing in the cause a characteristic energy and philanthropy in which Italy lags far behind. The "Istituto dei Rachitici" in Milan, however, the only Italian institution of the kind worth mention, has already done excellent work by its "Scuola di Lavoro" (school of labour), shortly to be supplemented (thanks to Donna Fanny Finzi Ottolenghi) by a "Casa di Lavoro" (house of labour) in which the instruction given in the school will have taken effect in actual production, placed as it will be under the skilled administration of the Istituto dei Rachitici. These houses of labour in other countries have succeeded in making 90 per cent. of the cripple and the maimed wage-earners and bread-winners, a proportion which in Italy would redeem 40,000 unfortunates from the misery and squalor in which they now live and die. Their effect in reducing her mendicancy—one of her most crying opprobria—is only too manifest. Dr. Galeazzi, in the course of his most interesting address, gave authentic instances of how literature, fine art, mechanical appliances, even science itself, had been enriched by the cripple and the maimed when the process of rescue and instruction had been opportunely begun and steadily carried out, illustrating his remarks by "projections" which placed in luminous relief the genius, artistic and mechanical, evoked from "society's victims" when taken in hand and treated skilfully in time. He concluded by an appeal to the medical auditor (who, as stated, was numerously represented in the assembly) to coöperate in the work by giving his invaluable aid in the prompt reporting and due selecting of subjects for the "Scuola" and the "Casa" of Labour alike—subjects who, in the practitioner's judgment, might profit by these institutions and give prestige and support to their beneficial mission.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Professor August Forel on the Tasks of Social Hygiene in the Twentieth Century.

ON the occasion of Professor August Forel's visit to Budapest for the purpose of delivering an address on the Tasks of Social Hygiene in the Twentieth Century the town-hall was selected as the place of meeting and there was a very large attendance. Before presenting the chief points of his discourse I may give some particulars relative to his life and scientific work. He is a tall, grey man, lively in demeanour, and a quick speaker. He was born in the French-speaking part of Switzerland in 1848. He holds the degrees of doctor of medicine and doctor of philosophy. He was formerly assistant at the psychiatric clinic in Vienna, afterwards becoming professor in the University of Zürich, and now he practises his profession in Yvorne, a small village in Switzerland. He has never been wealthy, although enjoying a reputation which brings patients from all parts of the world to seek his advice. The two subjects which have formed the chief pursuits of his life are the treatment of mental diseases and the natural history of ants, the former being his professional occupation, while the latter is his pastime. On the subject of ants he has written one large work, together with more than 100 shorter memoirs in which he has described an immense number of varieties of these insects. As a boy of 16 years he undertook an experiment with a view to ascertain whether the community exists only as long as the mother ant survives. He made an anthill on the yard of his father's house and studied the insects for 10 years. When 30 years of age he became professor and director of a large lunatic asylum in Zürich, but in 1898 he resigned both appointments in consequence of a dispute with the Cantonal Government and entered on private practice. The great success of his first considerable work, "Die Sexuelle Frage" ("The Sexual Question"), is shown by its being translated into French, English, Hungarian, Swedish, Italian, and Spanish. The proceeds of the sale of this book enabled him to buy a house in Yvorne where he lives with his family and with two or three resident patients. Indifferent to the so-called pleasures of life and limiting his personal wants to the mere necessaries of existence, he passes the whole day in mental application and regrets as lost the time which has been otherwise employed. As already mentioned, his audience in the town-hall at Budapest was very large, comprising about 2000 persons, most of whom were medical men. He began his discourse with a survey of the progress and development of mankind during last century, saying that the most notable figure of the nineteenth century was neither Bismarck nor Napoleon but Darwin. He considered that the immense development of industrial undertakings has made the people of the present day very self-conceited. They are inclined to over-estimate their own mental capacity in comparison with the men of olden times and other continents. It cannot be denied that certain races of mankind are superior in brain power to some other races. For instance, mental work like that of the white races could never be expected from negroes. It has, however, been a great mistake on the part of the white races to underestimate the immense progress, both material and intellectual, which the Japanese have made during the last 30 years. Some people say that the Japanese are only imitating us. But did not the European nations in the fifteenth century, the age of the Renaissance, imitate the Greeks and the Romans? And do they not now acknowledge the fact with justifiable pride? There was no difference, he said, between the mental capacity of the ancients and the moderns; the only difference was that we, the moderns, had inherited the experience of our ancestors and the great stock of scientific knowledge which they had accumulated with immense diligence and pains. We have in this way learned a great deal which was unknown to the Greeks and Romans. While over-estimating the triumphs of technics and industry we not only forget the reverence and respect due to the individual, but we lose sight of the great and important question how the human race can be improved and brought nearer to perfection. It is a false estimate of human duty not to prevent the propagation of the race by individuals of imperfect mental and physical development. One of the most important tasks of social hygiene and the medical profession was to prevent degenerates from propagating. It was also necessary to demolish several false gods—first of all, Bacchus and Gambrinus, who were a constant peril to the human race. Alcohol weakened the mental power even of those who took it in strict moderation. To remedy these many miseries of mankind was the task of social ethics, and those who worked in this good cause took for their motto the words, "Let us give more to the community than the community gives to us." The idea embodied in social ethics was self-sacrifice on the part of the individual for the good of the community, whereas sacrificing for one person was a kind of egoism. Women ought especially to beware of it. In some respects the female brain was inferior to the male brain, but in the qualities of mental alertness, sympathy, and perseverance women were decidedly superior to men. Social ethics have for their necessary supplement social hygiene, which aims at producing healthier and happier generations. Both of them aim at the prevention of human misery. Both of them, therefore, denounce alcoholism and the passion for money-making which presses so heavily on the masses and converts the working classes into mere proletarians. Both of them alike inculcate sexual purity and early marriage. Prostitution ought to be abolished by removing its causes and not by vain attempts to enforce repressive police measures. A student, aged 22 years, who loved a girl, aged 18 years, asked Professor Forel to advise him what to do, because some time must elapse before he could marry her on account of his inability to maintain a wife and the child who was to be expected. Professor Forel's advice in such cases is that the lovers should marry but should postpone procreation until their circumstances improve. Unhealthy and degenerate married couples who are for that reason ill adapted to be the parents of the coming race ought in his opinion to postpone procreation indefinitely. To forbid such people to marry would be inhuman, but to encourage them to propagate would be contrary to the interests of posterity. Professor Forel argues that as the earth is already sufficiently peopled now is the time to give preference to quality over quantity in the population. As a means of furthering this object he considers the artificial limitation of births to be justifiable. Suitable instruments for accomplishing such limitation have been devised and the use of them cannot be considered immoral. It would be just as reasonable to assert that it was immoral to wear spectacles which similarly do not belong to the body. Professor Forel is a zealous advocate of the emancipation of women, which he expects to be a leading feature of the twentieth century. Among the lower animals, he said, there is no example of the male making a slave of the female, this system being confined entirely to the human family. Women were justified in claiming the right of voting and it was a matter of astonishment to him that some women were indifferent to the attainment of this right. Finally, he expressed a hope that the time would come when all differences of nationality and language would be smoothed away. He was therefore an ardent supporter of Esperanto, a universal language which would bring the nations nearer to each other in the great work of humanity.

June 1st.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Sudden Death of a Prominent Surgeon in Western Canada.

IN the early morning of April 24th Dr. W. S. England of Winnipeg, Manitoba, died from cerebral hæmorrhage. He was 40 years of age. To not many of Canada's surgeons did success come so early in life as to Dr. England. Born in the province of Quebec 40 years ago he matriculated at McGill University, Montreal, in 1885 and received his degree with first-class honours from the same institution in 1889. After spending a year as interne in the Montreal General Hospital he proceeded to Winnipeg, and that he was made of more

Professor Orth (the successor of Virchow) who mentioned that Virchow's famous book on Tumours was left unfinished and especially in regard to the chapter on Cancer. He informed the meeting that this chapter had been written by the late *savant* but that at the time when it was to be printed new researches on cancer were published by Professor Waldeyer and Professor Thiersch in which Virchow's views were corrected. He agreed fully that his views must be revised but he had no time to rewrite the chapter on Cancer and therefore preferred to let his work appear in an unfinished state. The speaker said that if Virchow had witnessed the new experimental era of cancer research he would have undoubtedly brought his views into accordance with the new researches.

The first scientific paper was read by Professor Borrel of the Pasteur Institute of Paris on the problem of the etiology of cancer. He gave a historical survey of the views on cancer, saying that the question had gradually developed from a metaphysical problem to a matter of experiment. Alluding to the work of Ehrlich, Jensen, Bashford, and others, he pointed out the great importance of the discovery that cancer may be transplanted from one animal to another and that sarcoma may in the course of the implantations develop. It is stated that in cancer the normal cells become transformed and that at the same time they acquire the faculty of multiplying in an abnormal degree. The cause of the transformation and of the multiplication is, however, not yet ascertained; it is probable that they are produced by a certain virus, but all efforts to identify it have hitherto ended in failure. Professor Dollinger of Budapest then spoke on some results of the Hungarian statistics on cancer. He drew attention to the fact that in cancer the number of deaths is three times greater than the number of patients who had been under the care of medical men. It must thus be concluded that many of the patients are not aware of their disease or that they suffer so little that they do not require medical attendance. He then mentioned that in Hungary the number of cases of cancer in the country is only one-third of the number observed in towns and he gave a report of the frequency of cancer in the different organs. He concluded from the statistical tables that cases of cancer in which diagnosis and operation have been early have a lower death-rate than others.

Professor Jensen of Copenhagen discussed some problems of experimental cancer research, including researches on growths in larger animals and the causes of the alteration of the histology of cancer after the growth had been conveyed from one mouse to another. The cause may be in a peculiarity of the tissue of the second animal, in the internal qualities of the growth, or in a kind of pure culture produced by the frequent transplantations. Further problems were the action of different rays on cancer, the eventual discovery of an antiserum, and immunity. The fact that a certain species of mouse which was very much disposed to cancer in Frankfort became exempt in Norway leads to the conclusion that the climate, the alteration of food, &c., might be of importance. Experiments must further be made regarding heredity but 100,000 animals and coöperation amongst the different laboratories would be necessary for these investigations. The last paper was read by Professor Podwyssowski of St. Petersburg who spoke on the theory of irritants. He said that the irritation theory was one of the oldest theories to account for the development of cancer. As the result of recent researches it had been stated that certain irritants had an influence on the structure and the chemical composition of cells, so that they were right to suppose that those irritants might influence the development of cancer also as suggested by the late Professor Virchow.

June 1st.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Italian Association for the Advancement of Science: Its Second Meeting.

THE "Congresso Italiano per il Progresso delle Scienze"—an "association" organised on the lines of the "British" and, after two abortive attempts within the last 60 years, successfully inaugurated at Parma last autumn—will hold its second meeting from Oct. 18th to 25th in Florence—time and place being *motivé* by the fact that about that date the third centenary of Evangelista Torricelli will be celebrated in the "City of Flowers," associated as she is with the best and latest work of that master in physics, theoretical and applied. An honorary committee, the President of which is His Royal Highness the Count of Turin and the *personnel* of which includes the first names in science, literature, and fine art, as well as distinguished members of both Houses of Parliament, has held its inaugural meeting in the Palazzo Vecchio (Town Hall) of Florence, at which the arrangements for the due carrying out of the programme of the association were the subject of harmonious conference. The municipality will lead off with a reception of the "Congressisti" in the Palazzo Vecchio, while the "Deputazione Provinciale" will not be behindhand in similar hospitalities held in the Palazzo Riccardi. The halls of the Leonardo da Vinci will also be placed at the service of the association. The city and commune will liberally subsidise the "war-chest" of the meeting and the Government is expected to contribute towards the funds already announced *ad hoc*. The working committee or "comitato scientifico" will have as President the Senator Vito Volterra, professor of applied mathematics in the University of Rome, and as Vice-Presidents a body of *savants* in which the medical calling is largely represented to preside over the sections and sub-sections in which the work of the association will be carried out. That work will be classified under three main catagories: (1) that of the mathematical, physical, and chemical sciences; (2) that of the biological sciences; and (3) that of the moral or humanistic sciences. These again will be subdivided into sections and sub-sections to be determined "a seconda delle opportunita di tempo e di luogo" (according as time and place may indicate), to be announced, moreover, at a convenient date. No effort will be spared to improve upon the success already achieved at Parma and to make the last fortnight of October next a memorable one for Florence and for those of the outer world who find attraction in science as well as in history and art.

The Cripple and the Maimed.

On May 29th Dr. Riccardo Galeazzi, professor of orthopædia and privat-docent in clinical surgery in the University of Turin, also Director of the Institution for the Care and Cure of Rachitis in Milan, gave in the latter city a lecture on the schools and workhouses for the cripple and the maimed. His audience was a distinguished as well as a numerous one, many practitioners of medicine and surgery, general and consultant, being in attendance. After an eloquent tribute to Dr. Pietro Panzieri, Italy's apostle in the relief and reclamation of the physically deformed, Professor Galeazzi stated that the proportion of "storpi e mutilati" (cripple and maimed) in society as a whole is 1 per 1000 of the population, while Italy has no fewer than 175,000, of whom 116,000 live in the most squalid misery. To come to the rescue of such Germany has 33 "schools of labour" (workhouses) with 2660 pupils, while Denmark, Sweden, and Norway are at the head of the movement, other nations having few such institutions or none at all. America, he remarked, is showing in the cause a characteristic energy and philanthropy in which Italy lags far behind. The "Istituto dei Rachitici" in Milan, however, the only Italian institution of the kind worth mention, has already done excellent work by its "Scuola di Lavoro" (school of labour), shortly to be supplemented (thanks to Donna Fanny Finzi Ottolenghi) by a "Casa di Lavoro" (house of labour) in which the instruction given in the school will have taken effect in actual production, placed as it will be under the skilled administration of the Istituto dei Rachitici. These houses of labour in other countries have succeeded in making 90 per cent. of the cripple and the maimed wage-earners and bread-winners, a proportion which in Italy would redeem 40,000 unfortunates from the misery and squalor in which they now live and die. Their effect in reducing her mendicancy—one of her most crying opprobria—is only too manifest. Dr. Galeazzi, in the course of his most interesting address, gave authentic instances of how literature, fine art, mechanical appliances, even science itself, had been enriched by the cripple and the maimed when the process of rescue and instruction had been opportunely begun and steadily carried out, illustrating his remarks by "projections" which placed in luminous relief the genius, artistic and mechanical, evoked from "society's victims" when taken in hand and treated skilfully in time. He concluded by an

Leading citizens were asked to coöperate with the authorities. In some instances the former arranged a sort of "At Home" for inoculation purposes; they fixed a day and a time and issued invitations to their friends (and not always to friends alone) to attend and to be inoculated. Sometimes, instead of using a private residence, a shamiana was erected in the street in the front of some house, the occupant of which took the lead in trying to get a large assembly of friends and others. There was music to let the local world know that something special was going on. There were sweetmeats for children and sometimes refreshments for adults, the immediate aim being to popularise inoculation, and it was gratifying to note how each man tried to improve upon the work done by others. It seemed to become almost a point of honour to attract as many people as possible—not as mere onlookers, but so that a "record" in the number of inoculations might be made. Mahomedans and Hindus entered into a kind of competition and when it is said that on one morning 714 persons were inoculated there cannot be a doubt that friendly rivalry helped to swell the figures. The residency surgeon from whom came the original suggestion regarding a house-to-house campaign against plague had somewhat different methods in view from those that were finally adopted but he was no doubt pleased with the results of the revised plan the working out of which owed its success to his energy and tact.

Advantages from Inoculation.

As to the advantages resulting from inoculation it may be said that less than a score of cases of plague have occurred among the 27,512 persons inoculated, and only seven cases ended fatally. This is in striking contrast to the record of 1207 cases, of which 1008 proved fatal, among the uninoculated population. In several cases superficial abscesses formed at the point of inoculation, but these all yielded to medical treatment and in no single instance were there any ill effects of importance. On the one hand, specific cases might be cited as demonstrating the efficacy of inoculation as a preventive of plague. On the other hand, a number of people have been disabused of erroneous ideas concerning the supposed harmful effects of inoculation. There have been instances of fairly intelligent people believing that anti-plague inoculation led to one evil consequence or another. The closest observation conducted under conditions highly favourable to the ascertainment of facts has revealed nothing in the case of the many thousands of people who have been inoculated here to give ground to such belief. It should be added that the success that has attended anti-plague inoculation in the civil and military station of Bangalore is the more remarkable because of the fact that until quite recently the authorities in the city of Bangalore took no similar action. City and station adjoin each other; there is an incessant flow of intercourse between the people of the two places and plague or any epidemic in the one cannot but seriously threaten the public health in the other.

A Pasteur Institute for Burma.

The provision of a Pasteur institute for Burma is now assured, but some little time must elapse before the work can be started. The local community has come forward liberally in subscribing the better part of one lakh of rupees and the Government of India is understood to be addressing the Burma administration on the subject of ways and means for carrying the scheme into effect, the total cost of such an institution being, of course, much in excess of the sum that has been raised. The good beginning which has been made, however, insures that the scheme will be persisted with.

Proposed Legislation for Vaccination in Burma.

Leave will be asked at the next meeting of the Burma Legislative Council to introduce a Bill for the prohibition of inoculation and the licensing of vaccinators in Burma. The statement of objects and reasons shows that at present inoculation may be performed legally in any rural tract in Burma. It is a common thing throughout the province and its undoubted danger has been represented by successive vaccination officers. Since, however, the practice has been regarded as a safeguard by the people it is not possible to prohibit it except where full protection can be offered by the provision of a thoroughly efficient system of vaccination. It is possible to effect gradually the necessary improvements in the vaccination staff of one local area after another and inoculation can be prohibited gradually until the prohibition has extended throughout the province. A penalty extending to three months' imprisonment or a fine up to Rs.200, or both, is provided for anybody performing or undergoing inoculation in a specified local area. It is not proposed to make vaccination compulsory in rural areas. The Bill also provides for the licensing of vaccinators. At present vaccination, like inoculation, can be performed in rural areas by anybody, and it has been found that vaccination by unqualified persons entails serious risk. The Bill, therefore, only permits persons to perform vaccination who are licensed by the Government, and a penalty extending to one month's imprisonment or a fine up to Rs.50, or both, is provided for in cases of the infringement of the law.

Motor Ambulances.

The Rangoon General Hospital authorities have invested in a 30 horse-power motor ambulance which is fitted with a spring mattress and inflated rubber cushions and pillow for a patient who cannot sit up and seats for two patients who can. The new ambulance is said to be a vast improvement on the old dhoolies which it has replaced.

Plague in India.

The latest plague returns show that though the disease is widespread in a number of provinces heavy mortality is practically confined to a few cities and districts. In the Bombay Presidency, out of 1561 deaths for the week ending May 4th, 496 occurred in Bombay city alone, 201 in Karachi, and 208 in Baroda State, while there were only 69 in the whole of the Southern Division. In Bengal, for which the figures for a fortnight are given, the deaths in Calcutta were 266, but the Presidency division outside the city was practically free from the disease. In the Burdwan division, in which are included Howrah town and district, the figures were 12, but in the Patna and Bhagalpur divisions the mortality in the Patna, Saran, Darbhanga, Shahabad, and Monghyr districts was comparatively high. Chota Nagpur and Orissa together returned only one case. In the United Provinces, out of 1280 deaths in the week, Mainpuri district reported 167, Muttra 156, Azamgarh 124, and Unao 107. In the whole of the Meerut division only two deaths occurred, both in the Dehra Dun district. Big towns, such as Allahabad, Lucknow, Benares, and Bareilly, reported no cases. In the Panjab, with 2543 deaths, 1458 took place in the Delhi division, 619 of these being in the Gurgaon district. In Rajputana, out of 583 deaths, 273 occurred in Jaipur city and 134 in Alwar State. In the whole of the Rawalpindi division there were only 37 deaths. Compared with the returns of last year the figures are small indeed, and although they are rising there are no signs of large areas being swept by the epidemic. The most disquieting fact, perhaps, is the recrudescence of plague in Bombay city, where so much has been done to stamp out the disease.

Plague in Mysore State.

Dealing with the 1907 report on plague administration in the State during the same year the Mysore Government notes with regret that the plague seizures and deaths in the State numbered nearly double those of the previous year. While the Shimoga and Chitaldrug districts were comparatively free the city of Mysore and the districts of Bangalore, Hasan, and Kadur suffered largely and mainly contributed to the increase. It is observed that no specific reasons for this large increase are given by the sanitary commissioner who only states that in many villages both the people and the officials concerned show a lack of vigilance and promptness of action in dealing with plague preventive measures. But there is abundant reason to believe that in the vast majority of cases individual houses and entire villages have been evacuated on the appearance of plague or even of dead rats, the people camping out in fields and other open spaces in huts constructed by themselves or with the aid of materials supplied by the Government free of charge or at concession rates, and returning to their houses only after these have been lime-washed and cleaned and oftentimes disinfected with chemicals. Health camps provided by the Government in large towns have also been availed of. It has often been noticed, however, that when a village is evacuated the inhabitants move only a short distance away from the infected village, as, for instance, across a road. Such evacuation must be quite useless as there is nothing to prevent the rats from traversing the few yards intervening between the temporary sheds and the infected houses. Hence, with a view to evacuation having a reasonable chance of being successful, the sanitary than ordinary stuff is seen from the fact that at the time of his death he was professor of anatomy in the Manitoba Medical College, chief surgeon to the Winnipeg General Hospital, and also consulting surgeon to the St. Boniface Hospital of that city. The late Dr. England was a keen surgeon, thorough in his work, and of the very best judgment.

The Toronto General Hospital and the University of Toronto.

The complaint recently made in the public press of Toronto that the board of governors of the Toronto General Hospital in making the recent medical and surgical staff appointments had not dealt fairly by the medical faculty of the University has called forth from one of the members of the Senate of the University of Toronto, who is also a representative on the board of governors of the Toronto General Hospital, a reply, and as it places the connexion of the two institutions in a clear light some of the details will be interesting. Under the written agreement with the University of Toronto the Toronto General Hospital received $300,000. The city of Toronto contributed $200,000 and subscribers $700,000. The old hospital board brought in assets to the value of about $1,000,000. The specific agreement with the University called for the purchase of a block of land directly opposite the University holdings and the immediate erection of a modern hospital building to cost not less than $900,000. The section of the written agreement which would appear to make the members of the medical faculty of the University *ipso facto* members of the hospital staff reads as follows :—

> Medical Students.—The trustees shall allow any medical student of the University of Toronto to visit the wards of the hospital for the purpose of receiving instruction from the members of the Faculty of Medicine upon the payment of such fees and under such regulations and restrictions as the trustees may by any resolution or by-law from time to time appoint.

The writer goes on to say :—

> This is the agreement, and it certainly does not make the members of the medical faculty *ipso facto* members of the hospital staff. In my opinion it would be against both the interests of the University and the hospital if it did. How could the hospital maintain discipline on its staff or administer the affairs of the hospital if members of an outside body appointed by a different authority were to occupy positions on the hospital staff without being responsible to the hospital board? How can the board be made responsible for the care of the sick if it has not the power to appoint and remove those who attend them? A member of the staff who was incapable or neglectful of his duties could retain his position in spite of the board of the hospital if he happened to be a member of the Medical Faculty of the University.

Under the Hospital Act the board of governors of the Toronto General Hospital consists of 25 members, of whom five are appointed by the University of Toronto, five by the city of Toronto, eight by the Ontario Government, and seven by the subscribers. The strong point is made that the Toronto General Hospital is not a university hospital, yet nearly all the members of the new staff are members of the Medical Faculty of the University. That is to say, the old hospital board which brings assets to the value of $1,000,000, the subscribers with their $700,000, and the city of Toronto with its $200,000 donotion, are represented by a handful of city practitioners, while the University with its $300,000 donation controls at least nine-tenths of the staff.

The Feeble-Minded in Ontario.

Dr. Helen MacMurchy a short time ago, by command of the Ontario Government, made a careful inquiry into the history and present condition of the feeble-minded in the province of Ontario, the object being to further the proper care of them. Dr. MacMurchy says :—

> The only satisfactory method of dealing with the problem of the feeble-minded is to recognise mental defect in children, training them, and giving them all through life the care and supervision that will enable them to earn at least a part of their living, and protect them from the crimes and evils that threaten them in the outside world. Special classes in the public schools and special institutions for those needing permanent care are required for these. Where special classes have been tried in Great Britain, on the continent of Europe, and in the United States it is found that more than two-thirds of the children who are in them are seriously defective mentally and will always be dependents. From the special schools then, as a rule, they are taken to a special institution as their permanent home. These children should be taken charge of about the age of six or seven. Some of them can be taught to read, write, and do arithmetic. A part of their time should be spent in learning useful trades and occupations. As they grow older they should be treated somewhat differently, and any of them who can act as helpers, attendants, and members of the staff of the institution should be placed in these positions, but the really feeble-minded should never be allowed to go out into the world. No training or supervision will ever change the defective mind into a normal one. It is always to be remembered that in providing for the care of the feeble-minded the Government and the people are not taking up a new burden. We pay the cost of their maintenance now, while they should pay the cost of their own way partly or wholly by working under supervision. The jails, the Mercer reformatory at Toronto, the hospitals, the refuges, and the county poor house, have a number of feeble-minded persons as inmates.

Presentation to Dr. Walter B. Geikie.

A life-size portrait of Dr. Walter B. Geikie, Toronto, formerly Dean of Trinity Medical College and for over 40 years actively engaged in medical teaching in Toronto, was presented to him recently by former students and by him presented to the Academy of Medicine, Toronto. The presentation was made on behalf of the graduates in medicine of Trinity College by Dr. George A. Bingham who referred to the 51 years of Dr. Geikie's life as a medical teacher. Dr. Geikie spoke in feeling terms of his life work and said that 32 of his years, from April, 1871, until June, 1903, had been devoted to the founding and building up of Trinity Medical College which in 1903 amalgamated with the Medical Faculty of the University of Toronto.

Toronto, May 18th.

INDIA.

(FROM OUR OWN CORRESPONDENTS.)

The Frontier Campaign.

ALL the home papers have given full details of the mobilisation of a field force styled the Mohmand Field Force on the frontier to operate against the Mohmands. The force consisted of three infantry brigades, each containing one British and three native infantry battalions, with two sections of a British and a complete (four section) native field hospital, divisional troops having also a complete native field hospital. The principal medical officer of the force is Colonel H. R. Whitehead, R.A.M.C., and all the field hospitals have been equipped with ambulance riding animals (half accompanying the first advance) and as far as possible with dandies on the regulation scale, with full complement of Army Bearer Corps men, half the dandies and bearers being held in readiness at the base (Peshawar) until required. A native base hospital has been formed at Peshawar. Others are apparently mobilising at Lahore Cantonments and Rawal Pindi. Up to date of writing the casualties amongst the troops employed have been small and apparently all the wounds are gunshot, the few fatal cases being abdominal. Under the present peace organisation each division has a complete x ray apparatus belonging to it, with several specially qualified x ray specialists in charge. This x ray equipment is arranged so as to be capable of being moved on service and employed in the field hospitals if required. Each division has also a complete staff of specialists in sanitation holding the D.P.H. diploma, and also specialists in advanced operative surgery will accompany the division when mobilised for field service.

The Campaign against Plague in Bangalore.

Bangalore is very proud of itself just now and not without reason. Of the civil population alone 25,174 have been inoculated with the anti-plague serum, and this is a record that cannot be touched by even India's largest cities. Including the military section of the local population 27,512 people have been inoculated (up to April 10th, 1908). These are large figures and possible residents in other stations may be interested in a brief note of the manner in which the above total has been reached. At the present time what is called house-to-house inoculation is the special feature of the campaign that is being waged against plague in Bangalore. Since this system was started on Dec. 21st, 1907, no less than 11,393 persons have been inoculated. The original intention was to adopt a true house-to-house system. It has been found that many people were indifferent or even hostile to inoculation, while many others were quite unable to attend at the inoculation stations that were established. In these last a great deal of excellent work was done and the lower classes were induced to flock to the different centres arranged from time to time and to submit themselves to the, to them, new kind of operation. There were many residents, however, who held aloof, whether voluntarily or not, and the authorities thought that they might apply the old principle of "if the mountain will not go to Mahomet, Mahomet must go to the mountain."

Inoculation Procedure.

The procedure that was finally adopted was very simple.

Commissioner has issued orders requiring detailed reports about the sanitary condition of the people and the roads with a view to improve the health of the general public, especially during the coming hot weather. Tientsin is the commercial capital of North China and each of the foreign concessions in it has its own municipality and public health regulations but hitherto nothing in matters sanitary has been done in the densely populated Chinese city.

The Stamping-out of Opium Smoking.

I append a translation of the latest Imperial Edict on the opium habit to enable your readers to see for themselves the active efforts which the Chinese Court and Government are making to suppress a national vice.

IMPERIAL EDICT, 7TH APRIL.

Ching Hsin and Ting Shen-tao are appointed special commissioners in charge of the work of opium suppression. They are required to ascertain whether there are any officials either in Peking or the provinces still smoking opium, and to draw up regulations to deal with officials still guilty of this habit. Her Majesty the Empress Dowager has been informed that there are still some officials breaking the rule, and the Grand Council is hereby authorised to dismiss any official from the rank of Viceroy down who persists in smoking. The two above officials are held responsible in this matter and they are granted taels 30,000 for initial expenses of their work and to open their office, and taels 60,000 annually to maintain it. It is to be kept up until the opium habit is entirely stopped.

April 9th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Climatology of Australia.

Mr. Hunt, the Commonwealth meteorologist, has issued a report dealing with the above subject. Mr. Hunt considers that Australia is, by reason of its insularity and the absence of striking physical features, less subject to extremes of weather than are regions of similar area in other parts of the globe, and that, latitude for latitude, it is more temperate. The hottest area of the continent is situated in the northern parts of West Australia, about the Marble Bar and Nullagine goldfields, where the maximum *shade* temperature exceeds 100° F. for weeks continuously. The coldest area is in the extreme south-east of New South Wales and extreme east of Victoria, where in the region of the Australian Alps the shade temperature rarely if ever exceeds 100°. The average rainfall of Australian cities affords some surprising comparisons with other great world centres. London has an average 2 inches below that of Melbourne, Edinburgh 1·31 inches less, San Francisco 4 inches less, and Berlin about the same. Amsterdam, Christiania, Copenhagen, Paris, Moscow, St. Petersburg, and Stockholm are all below. The wettest Australian town is Geraldton, on the Queensland coast, where the average rainfall is 145 inches (maximum 211, minimum 69). Lake Eyre district in South Australia has an annual average of only five inches. Mr. Hunt thinks that the Australian "southerly buster" is of like character, and probably derived from similar atmospheric conditions, as the "bora" of Dalmatia, the "mistral" of France and the Gulf of Lyons, and the "pampero" of South America.

Children's Hospital, Sydney.

At the annual meeting of the supporters of the Royal Alexandra Hospital for Children Mr. C. P. B. Clubbe said he regretted that the hospital was not supported as it should be by the public. If the public would not support these institutions there must be a hospital tax imposed. Mr. Dorman, representing the Hospital Saturday Fund, said that the hospital certainly did not receive enough money from the Government. Recently there had sprung into existence a number of institutions calling themselves medical charities which were not fit to bear the name; many institutions which had proved their utility were languishing while funds were being diverted to these others. The public gifts should go through some channel by which they would be properly distributed.

Vital Statistics of Sydney.

During the quarter ended March 31st the metropolitan birth-rate was 6·26 per 1000 of population. The births numbered 3577. There were in the same period 1519 deaths, equal to a rate of 2·76 per 1000. This birth-rate is 7 per cent. and the death-rate is 5 per cent. higher than that of the corresponding period of 1907.

Infectious Diseases Hospital, Melbourne.

In 1891 it was decided to build a hospital for infectious diseases in Melbourne. The project lingered until 1897 when it was finally decided to build in commemoration of the Diamond Jubilee of the late Queen Victoria and to name the institution the Queen's Memorial Hospital. The hospital was largely designed under the supervision of the late Dr. D. A. Gresswell and cost £18,250. Its history up to the time of completion was a series of disputes and dissensions among its promoters and since it was opened about five years ago it has never given complete satisfaction. The design is faulty and only scarlet fever and diphtheria patients are admitted, with the result that there are never more than two-thirds of the beds in use. The management is in the hands of a committee representing the various municipalities which contribute to the up-keep. Patients may be charged in some instances as much as 7*s.* 6*d.* per day. The dissatisfaction with the position and general management of the hospital is likely to be brought forward prominently in connexion with a complaint by the father of a recent inmate that his child was sent home in a dirty state. The hospital authorities deny that there is any ground for the allegation, but Dr. Norris, chairman of the Board of Public Health, wrote to the medical superintendent to the effect that the statements call for a more extended reply. The Inspector of Charities has furnished a report to the Premier in which he stated that the brown appearance of the skin of the child on his discharge was naturally due to open-air treatment but that his head was clean on admission and subsequently required treatment. The report states that "the hospital authorities were undoubtedly to blame in handing the child over to its parents other than in a thoroughly clean condition." The inspector also remarked that while the hospital was doing good work it required to be extended and popularised. At present it was difficult to obtain admission and charges for maintenance were excessive.

Melbourne Hospital.

The trustees of the Wilson Estate, who offered £100,000 towards rebuilding the Melbourne Hospital, practically directed that it should be rebuilt on the present site and the committee has concurred. The trustees have now invited architects to communicate with them in order that they may suggest a name to the hospital committee as they are entitled to do so under the terms of the gift. The gentleman selected must be prepared to spend at least six months in visiting and examining the most modern hospitals in Europe and America.

Diagnosis of Fractured Skull.

Within the space of a few days three cases have come before the Melbourne city coroner in which the deceased person had been found drunk, taken to the lock-up, become seriously ill in the cells, removed to the Melbourne Hospital, and died. In the last case the subject had been seen at the hospital prior to being locked up and refused admission. The coroner has expressed his opinion that the initiation of a State public medical service at night deserved consideration. He produced a copy of a London journal which contended that "the time will come, we hope, when a medical man will be engaged to attend at all police stations in large towns to do duty for a certain number of hours and to diagnose doubtful cases, render skilled aid in cases of accident and sudden attacks of serious illness."

Juvenile Smoking.

At Dimboola, an up-country centre in Victoria, the first case under the new Act for the prevention of juvenile smoking was heard at the local police-court. A lad was summoned for having given a cigarette to a companion who was under the age of 16 years. The lad receiving the cigarette appeared, however, to be over the statutory age and had made a statement to that effect. The case was dismissed but the police magistrate improved the occasion by a severe lecture to the recipient of the gift for having told an untruth as to his age.

Medical Registration in Victoria.

A deputation consisting of members of the Medical Board, the Council of the British Medical Association (Victoria branch), and the Melbourne Medical Association, waited on the Chief Secretary to request an amendment in the present Act relating to medical registration. As the Act at present stands one homœopathic practitioner may be admitted each year in Victoria provided he holds a diploma commissioner has been requested to prescribe a *minimum* distance to which the villagers should remove.

Importation of Cocaine.

A notification of the Government of India is published which prohibits the bringing by sea or land into British India of cocaine by means of the post, and restricts its importation by any other means to cases in which it is imported by persons or their authorised agents who have been specially permitted to import the drug by a local government or administration or by the Madras Board of Revenue.

Wild Animals in Madras.

During 1907 in the Madras Presidency the number of persons reported to have been killed by wild animals and snakes was 2041, or 197 more than in the previous year. There was a considerable increase in the number of deaths caused by tigers in Vizagapatam, by other animals in Tinnevelli, and by snakes in North Arcot. The number of cattle killed fell by 361. The decreases occurred principally in Malabar and South Canara, while North Arcot and Coimbatore report large increases. The total number of wild beasts for the destruction of which rewards were paid during the year was 797, or 109 less than in the previous year. The amount paid in rewards was Rs.13,698, or Rs.1133 less than in the previous year. Rewards aggregating Rs.2920 were paid for the destruction of 69 tigers. A sum of Rs.13,111 was spent during the year on the removal of noxious undergrowth which harbours snakes, &c.

May 7th.

NOTES FROM CHINA.

(FROM OUR OWN CORRESPONDENT.)

Disposal of Refuse in China.

IN view of the great expense entailed upon sanitary authorities at home in the disposal of refuse by the erection of septic tanks, refuse destructors, &c., it might be interesting to consider the universal system which has been in vogue from prehistoric times in China where such highly specialised procedures are quite unknown. China is essentially an agricultural country and the greater part of the Empire may be looked upon as being one vast sewage farm. Excremental refuse is not in any way regarded as a waste product here; on the contrary, its value is so great that the authorities do not attempt to regulate its disposal in any way, knowing well enough that it is dealt with in a very active manner by the people. Take, for example, this big city of Peking with three-quarters of a million inhabitants. Numbers of people earn a good living by being night-soil collectors. Here and there men build latrines in the streets, from which they collect the deposit of chance pedestrians, while every lane and street is the property of others as far as the house-to-house collection of excreta is concerned. In addition, there are large numbers of itinerant gatherers who perambulate the streets, bucket on back and spade in hand, with keen eyes for any stray deposit from either man or beast. Among the male part of the population the act of defæcation is not regarded as one requiring any privacy and thus it comes that various open spaces in the city are made conveniences of by passers-by. In the streets the night-soil collectors' wheelbarrow loaded to the buckets' brims jostles the mandarin in his carriage or the itinerant purveyor of food. All this refuse is taken to the outskirts of the city, where there are "clearing houses" from which the farmers buy. No fields are ever allowed to lie fallow. Not only that but they are forced by means of this liberal manure dressing to raise two crops of corn a year. In the case of rice the soil is first prepared with manure which is thickly spread over the surface, then by flooding the fields with water a mixture of unsavoury slush is made. Vegetables such as turnips, cabbages, tomatoes, and egg plants are treated in the same way as the cereals. It is to this whole system that the extraordinary fertility of the land is due, but here also lies the cause of the high prevalence of intestinal parasitism. Over 60 per cent. of Chinese harbour one or another of these parasites; so much so that in hospital practice it is generally found that a useful routine is to begin medical treatment by a dose of calomel and santonin. Thus in St. Luke's Hospital, Shanghai, Dr. Eli Day, working in conjunction with Dr. W. H. Jefferys, made an examination of 500 stools mostly from surgical cases with the following result. For the sake of greater accuracy the findings of the first 50 stools were excluded.

—	Single *infection.*	Mixed infection.	Total cases of infection.	Percentage.
Ascaris lumbricoides	151	96	247	54·8
Trichocephalus dispar (trichiuris)	22	89	111	24·6
Ankylostoma duodenale	4	21	25	5·5
Distoma sinense ...	2	—	2	0·4
Fasciola hepatica ...	—	2	2	0·4
Strongyloides intestinalis	—	1	1	0·2
Oxyuris vermicularis	1	—	1	0·2
Cases with positive findings	—	—	275	61·1

These examinations were irrespective of symptoms presented and are practically borne out by the results obtained in Hong-Kong public mortuary, where post-mortem examinations are performed on a scale neither attempted nor permitted in any place in China. In Hong-Kong ascaris lumbricoides has been found present in 90 per cent. of the bodies examined, trichocephalus in a fair proportion, and ankylostoma very rarely. Distoma sinense is next to ascaris the commonest parasite, being constantly met with in the bile-ducts and gall-bladder. A feature of note is the absence of cestodes among the Chinese; in fact, they are never met with except among those who indulge in foreign food or have returned from abroad. In my last letter I referred to the rarity of appendicitis among Chinese. Perhaps the similar rarity of cases of tapeworm may be more than a coincidence, as both these affections are present in countries where much and imperfectly cooked beef is eaten. The slice of underdone roast beef so popular at English tables is quite unknown in China. Trichina spiralis is another parasite that may be said to be absent in China, although pork is the commonest kind of meat eaten and the village pigs support themselves mainly by scavenging.

Union Medical College, Peking.

In response mainly to the indefatigable efforts of Dr. T. Cochrane, the principal of this college, the Imperial Government has followed up the Charter which it granted in 1906 by making an annual allowance. This may be looked upon as a more important step than it might at first sight seem, for it means a direct filip to the cause of scientific medicine, especially in this ancient city of Peking. It is the first Government grant given to any medical college under European direction. The teaching is in Chinese and no stone is being left unturned by the British and American staff of lecturers to make it as thorough as possible, though the terminological difficulties are great. This annual grant-in-aid is a concomitant to the Government's action in bestowing a charter, by virtue of which it is to be given facilities for satisfying itself through its own official examiners that graduates have been put in possession of a competent knowledge of their profession. This is therefore really the dawn of the foundation of scientific medicine in China and it behoves medical men at home to watch with interest this endeavour of their British and American *confrères* to establish the profession in a way that has not been done before. Graduates will go forth with Government-stamped diplomas and their work will no doubt be appreciated by a people whose eyes are being daily opened to the ameliorating effects of Western civilisation just as has happened in Japan. A German medical school has recently been opened in Shanghai. At present a beginning has been made in the preliminary scientific work and in the teaching of German as the course will be conducted in that language. The enterprise is said to be well supported. The present members of the scientific staff are Professor du Bois Reymond, Professor Ammann, and Professor Schlinger.

Appointment of Foreign Medical Police Officers at Tientsin.

By sanction of Viceroy Yung Shih-hsiang, the Chief Commissioner of the Chinese city police has engaged foreign practitioners to act as medical advisers to the police, fire brigade, and public works department which up to the present have had no regular medical help. In addition, the Chief

Commissioner has issued orders requiring detailed reports about the sanitary condition of the people and the roads with a view to improve the health of the general public, especially during the coming hot weather. Tientsin is the commercial capital of North China and each of the foreign concessions in it has its own municipality and public health regulations but hitherto nothing in matters sanitary has been done in the densely populated Chinese city.

The Stamping-out of Opium Smoking.

I append a translation of the latest Imperial Edict on the opium habit to enable your readers to see for themselves the active efforts which the Chinese Court and Government are making to suppress a national vice.

IMPERIAL EDICT, 7TH APRIL.

Ching Hsin and Ting Shen-tao are appointed special commissioners in charge of the work of opium suppression. They are required to ascertain whether there are any officials either in Peking or the provinces still smoking opium, and to draw up regulations to deal with officials still guilty of this habit. Her Majesty the Empress Dowager has been informed that there are still some officials breaking the rule, and the Grand Council is hereby authorised to dismiss any official from the rank of Viceroy down who persists in smoking. The two above officials are held responsible in this matter and they are granted taels 30,000 for initial expenses of their work and to open their office, and taels 60,000 annually to maintain it. It is to be kept up until the opium habit is entirely stopped.

April 9th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Climatology of Australia.

Mr. Hunt, the Commonwealth meteorologist, has issued a report dealing with the above subject. Mr. Hunt considers that Australia is, by reason of its insularity and the absence of striking physical features, less subject to extremes of weather than are regions of similar area in other parts of the globe, and that, latitude for latitude, it is more temperate. The hottest area of the continent is situated in the northern parts of West Australia, about the Marble Bar and Nullagine goldfields, where the maximum shade temperature exceeds 100° F. for weeks continuously. The coldest area is in the extreme south-east of New South Wales and extreme east of Victoria, where in the region of the Australian Alps the shade temperature rarely if ever exceeds 100°. The average rainfall of Australian cities affords some surprising comparisons with other great world centres. London has an average 2 inches below that of Melbourne, Edinburgh 1·31 inches less, San Francisco 4 inches less, and Berlin about the same. Amsterdam, Christiania, Copenhagen, Paris, Moscow, St. Petersburg, and Stockholm are all below. The wettest Australian town is Geraldton, on the Queensland coast, where the average rainfall is 145 inches (maximum 211, minimum 69). Lake Eyre district in South Australia has an annual average of only five inches. Mr. Hunt thinks that the Australian "southerly buster" is of like character, and probably derived from similar atmospheric conditions, as the "bora" of Dalmatia, the "mistral" of France and the Gulf of Lyons, and the "pampero" of South America.

Children's Hospital, Sydney.

At the annual meeting of the supporters of the Royal Alexandra Hospital for Children Mr. C. P. B. Clubbe said he regretted that the hospital was not supported as it should be by the public. If the public would not support these institutions there must be a hospital tax imposed. Mr. Dorman, representing the Hospital Saturday Fund, said that the hospital certainly did not receive enough money from the Government. Recently there had sprung into existence a number of institutions calling themselves medical charities which were not fit to bear the name; many institutions which had proved their utility were languishing while funds were being diverted to these others. The public gifts should go through some channel by which they would be properly distributed.

Vital Statistics of Sydney.

During the quarter ended March 31st the metropolitan birth-rate was 6·26 per 1000 of population. The births numbered 3677. There were in the same period 1519 deaths, equal to a rate of 2·76 per 1000. This birth-rate is 7 per cent. and the death-rate is 5 per cent. higher than that of the corresponding period of 1907.

Infectious Diseases Hospital, Melbourne.

In 1891 it was decided to build a hospital for infectious diseases in Melbourne. The project lingered until 1897 when it was finally decided to build in commemoration of the Diamond Jubilee of the late Queen Victoria and to name the institution the Queen's Memorial Hospital. The hospital was largely designed under the supervision of the late Dr. D. A. Gresswell and cost £18,250. Its history up to the time of completion was a series of disputes and dissensions among its promoters and since it was opened about five years ago it has never given complete satisfaction. The design is faulty and only scarlet fever and diphtheria patients are admitted, with the result that there are never more than two-thirds of the beds in use. The management is in the hands of a committee representing the various municipalities which contribute to the up-keep. Patients may be charged in some instances as much as 7*s.* 6*d.* per day. The dissatisfaction with the position and general management of the hospital is likely to be brought forward prominently in connexion with a complaint by the father of a recent inmate that his child was sent home in a dirty state. The hospital authorities deny that there is any ground for the allegation, but Dr. Norris, chairman of the Board of Public Health, wrote to the medical superintendent to the effect that the statements call for a more extended reply. The Inspector of Charities has furnished a report to the Premier in which he stated that the brown appearance of the skin of the child on his discharge was naturally due to open-air treatment but that his head was clean on admission and subsequently required treatment. The report states that "the hospital authorities were undoubtedly to blame in handing the child over to its parents other than in a thoroughly clean condition." The inspector also remarked that while the hospital was doing good work it required to be extended and popularised. At present it was difficult to obtain admission and charges for maintenance were excessive.

Melbourne Hospital.

The trustees of the Wilson Estate, who offered £100,000 towards rebuilding the Melbourne Hospital, practically directed that it should be rebuilt on the present site and the committee has concurred. The trustees have now invited architects to communicate with them in order that they may suggest a name to the hospital committee as they are entitled to do so under the terms of the gift. The gentleman selected must be prepared to spend at least six months in visiting and examining the most modern hospitals in Europe and America.

Diagnosis of Fractured Skull.

Within the space of a few days three cases have come before the Melbourne city coroner in which the deceased person had been found drunk, taken to the lock-up, become seriously ill in the cells, removed to the Melbourne Hospital, and died. In the last case the subject had been seen at the hospital prior to being locked up and refused admission. The coroner has expressed his opinion that the initiation of a State public medical service at night deserved consideration. He produced a copy of a London journal which contended that "the time will come, we hope, when a medical man will be engaged to attend at all police stations in large towns to do duty for a certain number of hours and to diagnose doubtful cases, render skilled aid in cases of accident and sudden attacks of serious illness."

Juvenile Smoking.

At Dimboola, an up-country centre in Victoria, the first case under the new Act for the prevention of juvenile smoking was heard at the local police-court. A lad was summoned for having given a cigarette to a companion who was under the age of 16 years. The lad receiving the cigarette appeared, however, to be over the statutory age and had made a statement to that effect. The case was dismissed but the police magistrate improved the occasion by a severe lecture to the recipient of the gift for having told an untruth as to his age.

Medical Registration in Victoria.

A deputation consisting of members of the Medical Board, the Council of the British Medical Association (Victoria branch), and the Melbourne Medical Association, waited on the Chief Secretary to request an amendment in the present Act relating to medical registration. As the Act at present stands one homœopathic practitioner may be admitted each year in Victoria provided he holds a diploma from one of two specified American colleges and spends a year subsequent to graduation as resident at the Melbourne Homœopathic Hospital. It was thought at the time that this would insure a five years' training such as is insisted upon for all registrable qualifications, since the American colleges named provided a course extending over four years. It has been discovered that a student who attended some lectures in the University of Melbourne, but passed no examination, proceeded to America and returned in 11 months with an M.D. degree from one of the two institutions named in the Act, and which the Board had no option but to register. Sir Alexander Peacock replied to the deputation that he had been asked to hear the homœopathic view and that he would refer the question to the Cabinet for consideration.

Railway Disaster.

The most appalling railway accident yet experienced in Australia occurred at Braybrook Junction late on Easter Monday night, when a stationary train from Ballarat was overtaken and run into by an express from Bendigo. 41 persons were killed outright and two have since succumbed, while upwards of 70 others were seriously injured and more than 150 minor claims have already been notified. Complaint has been made as to the delay of the railway authorities in affording relief but this does not seem justified. The accident occurred eight miles from Melbourne at an outlying suburban station a few minutes before 11 o'clock at night. Within five hours all the injured persons had received first aid from medical men on the spot and had been forwarded to hospitals in the city. Although the débris was stated to have taken fire none of the casualties appeared to be due to burning.

May 3rd.

Obituary.

FRANCIS RUTHERFURD RUSSELL, M.D., C.M. EDIN., J.P.

BY the death of Dr. Russell, which took place recently at Guildford, that borough has lost one of its most respected and prominent citizens. Born in 1853 at Jedburgh, he received his medical education at Edinburgh and in Vienna. In 1878 he graduated M.B., C.M., at the University of Edinburgh and in 1880 obtained the M.D. degree. In this year he went to Guildford where he soon became popular among all classes of the community. In 1902 he was elected to the Guildford town council and was repeatedly asked to allow himself to be nominated as mayor, but his busy life prevented his consenting to receive the honour which his municipal colleagues were willing to confer upon him. In 1904 Dr. Russell was placed upon the commission of the peace for the borough of Guildford. At one time Dr. Russell was an officer in the 2nd Volunteer Battalion, The Queen's Royal West Surrey Regiment, and later became Brigade-Surgeon-Lieutenant-Colonel to the West Surrey Volunteer Infantry Brigade. He took a keen interest in all that concerned the Volunteers and at the time of his death was one of the military members of the Surrey Territorial Association. He held the Volunteer Officers' Decoration. He was surgeon to the Royal Surrey County Hospital and medical officer to the National Fire Brigades Union. Dr. Russell's unexpected death at the early age of 55 years has been felt with keen sorrow by his professional and lay colleagues no less than by the residents of Guildford and its neighbourhood, both rich and poor.

EXAMINATION FOR WOMEN HEALTH VISITORS AND SCHOOL NURSES.—Hitherto health visitors appointed by local authorities to carry out sanitary inspection and visiting have mostly prepared themselves for their duties by taking the examination for inspectors of nuisances. The council of the Royal Sanitary Institute have now decided to establish an examination for health visitors and school nurses. The syllabus includes general structure of the body, personal hygiène, air, water, food, clothing, the dwelling, elements of home nursing, care of infants and young children, prevention of communicable disease, first-aid, treatment of injuries, ailments and accidents, and statistics. The examinations will be held from June to December in 11 of the large towns in the United Kingdom. The fee is £2 2*s*. Full particulars can be obtained on application to the secretary, Royal Sanitary Institute, Margaret-street, London, W.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The election of a Representative on the General Medical Council, in place of Dr. D. MacAlister, will take place on June 9th in the Senate House from 12 to 1.—The following degrees were conferred on May 28th :—

M.D.—H. M. Davis, W. M. Fletcher, and J. S. Pearson, Trinity; E. D. Macnamara, Pembroke; F. H. Edgeworth, Gonville and Caius; and A. H. Style, Emmanuel.
M.B., B.C.—F. W. W. Griffin, King's.
M.B.—J. McIntyre, King's; and L. H. L. Mackenzie, Trinity.
B.C.—A. Wilkin, King's; P. H. Smith, Pembroke; E. G. Wheat, Christ's; and A. J. May, Sidney Sussex.

THE Medical Golfing Society will hold its 1908 tournament on June 18th at the Guildford Golf Club by kind permission of that club. Intending competitors should send the annual subscription of 4*s*. (which includes entrance to the tournament) to Mr. L. Eliot Creasy, honorary treasurer, Medical Golfing Society, 51, New Cavendish-street, London, W., and must notify their entry, stating lowest handicap, on or before Tuesday, June 16th, to Dr. T. B. Hyslop, honorary general secretary, Bethlem Royal Hospital, London, S.E. The following are the particulars of the competition: 18 holes match play *v.* bogey under handicap. Class 1, handicaps 12 and under; Class 2, handicaps over 12. No previous play allowed on the day. A first and second prize, and a prize for the best last nine holes *v.* bogey will be given in each class. Members of the Guildford Golf Club deduct 2 from their handicap. The "Henry Morris" challenge cup will be awarded for the best score against bogey under handicap and the winner will also receive the Medical Golfing Society gold medal. A foursome sweepstake will be arranged in the afternoon.

ROYAL SANITARY INSTITUTE, LONDON.—A sessional meeting of the institute will be held at the Parkes Museum on Saturday, June 13th, at 11 A.M., when a discussion will take place on "The Pasteurisation of Milk," to be opened by Professor H. R. Kenwood. In the afternoon a visit will be made to the Sudbury Park Dairy Farm (Wembley) and the Walker-Gordon Laboratories, by invitation of Mr. and Mrs. Titus Barham, who are entertaining the members at a garden party. Particulars of trains and arrangements are given on the invitation cards or can be obtained by applying to the institute. On Saturday, June 20th, a provisional sessional meeting will be held at St. Mary's Hall, Coventry, when a discussion will take place at 11 A.M. on "Some Aspects of the Housing Problem and Town Planning," which will be opened by Dr. E. H. Snell, medical officer of health, and Mr. J. E. Swindlehirst, city engineer, of Coventry. Tickets for admission of visitors may be had on application to Dr. Snell, public health department, 10A, Hay-lane, Coventry, who is acting as the local honorary secretary of the meeting, or they may be obtained from Mr. E. White Wallis, the secretary of the Institute, at the Parkes Museum, Margaret-street, London, W.

GLASGOW UNIVERSITY CLUB, LONDON.—The members and friends of this club dined together on May 29th at the Empire Rooms, Trocadéro Restaurant, London, W. Professor David W. Finlay was in the chair, and in the course of his speech proposing "The University and the Club" he referred to the sad loss which they had all suffered in the death of Lord Kelvin, whose office as president of the club had been filled by Lord Lister. He announced with satisfaction that the club had been surely and steadily progressing and owing to the energy and capacity of Dr. C. O. Hawthorne it now numbered nearly 400 members. He regretted that Dr. Hawthorne, after seven years' service as honorary secretary, had tendered his resignation which had been accepted with reluctance in a resolution putting on record the high appreciation of all concerned of the worth of the services which Dr. Hawthorne had rendered to the club. Sir Henry Craik, M.P., submitted the toast of "The Visitors," coupling with it the name of Dr. Sidney Coupland, who acknowledged the compliment in a few well-chosen words. Professor John M. Thomson gave the toast of "The Chairman," to which that gentleman made a suitable response, and the proceedings terminated. An interesting item in the annual report was the gift of 50 guineas by the club to the Glasgow University Students' Union Extension Fund.

University of Manchester.—Three lectures on Cancer (Pilkington Cancer Research) will be delivered by Dr. C. Powell White on Wednesdays, June 17th, 24th, and July 1st, at 4.30 P.M., in the general theatre of the medical school. The lectures will be fully illustrated by means of microscopic preparations, museum specimens, and lantern slides projected by the epidiascope. Members of the medical profession and students of medicine are cordially invited to attend.

Queen Charlotte's Lying-in Hospital.—H.R.H. Princess Alexander of Teck will open the extension of the Nurses' Home of Queen Charlotte's Hospital on Tuesday, June 30th. The original home, which was opened in 1899, provided for nearly 70 nurses and the extension will accommodate an additional 35. The new building also comprises a residential college for students, with accommodation for 16 students and qualified practitioners. A sum of £10,000 is still needed to open the extension free of debt, and donations towards this amount are earnestly asked for.

THE annual meeting of the South Wales and Monmouthshire branch of the British Dental Association was held at Merthyr Tydfil on May 22nd. Mr. E. Hugh Musgrove, L.D.S. Eng., the President, in the course of his address alluded to the beneficial results which would arise from the medical inspection of children in elementary schools and complimented the Merthyr Tydfil corporation upon putting the Act enforcing this inspection into force so thoroughly. Some interesting demonstrations were given by Mr. J. C. Oliver, L.D.S. Eng., Mr. J. T. Willows, L.D.S. Irel., and others. The dinner took place in the evening, Mr. Musgrove presiding.

University of Oxford.—Mr. A. F. Hertz, D.M., Magdalen College, assistant physician, Guy's Hospital, has been appointed lecturer in materia medica and medical pharmacology for the year beginning with the first day of Easter term, 1908.—Mr. J. B. Leathes, B.M., New College, lecturer in physiology, St. Thomas's Hospital, has been appointed a public examiner in animal physiology, to hold office from the first day of the Michaelmas term, 1908, to the first day of Michaelmas term, 1910.—The examination in materia medica and pharmacy has been transferred from the first to the second examination for the degree of Bachelor of Medicine and the subject will in future be entitled "Materia Medica and Pharmacology."—The annual dinner of the past and present members of the medical school will be held in University College on Saturday, June 20th. It is intended that this year the meeting shall take the form of a farewell dinner to Dr. Gustav Mann who is leaving Oxford to enter on his new duties as professor of physiology at New Orleans, U.S.A. The secretary of the dinner is Mr. C. F. Beevor, Magdalen College.

The Welsh Medical Dinner.—The Welsh Medical Society held its fifth annual dinner at the Criterion Restaurant on May 29th, Mr. Edmund Owen, the President, being in the chair. After the honouring of the loyal toasts, the chairman paid an eloquent tribute to the qualities of the Principality in giving the toast of "The Medical Profession and the University of Wales." Mr. Owen, amidst applause, in the course of his speech, announced his own nomination as the representative of the British Medical Association on the Medical Board of the University of Wales. In speaking of the solidarity of his native land he alluded to the united front with which the whole medical profession had supported two of his compatriots, Mr. Lynn Thomas and Mr. H. E. Skyrme, in their recent time of trouble. Dr. Emrys Jones replied to the toast, followed by Mr. Lynn Thomas, who in response to an urgent call thanked the profession in very feeling terms for the support which had been tendered to himself and his colleague. Dr. Lloyd Owen proposed "The Guests," for whom Dr. Ambrose responded, the last toast being "The Chairman," which was given by Mr. J. H. Morgan and drunk with musical honours. As was to be expected at a Welsh gathering, a programme of most admirably rendered vocal music contributed to the success of the evening, the artists being Miss Edith Evans, Miss Gwladys Roberts, and Mr. John Roberts, accompanied by Mr. E. T. Davies, F.R.C.O.; the songs included the Welsh anthem, "Fy Anwyl Hen Wlad," and "Galwad y Tywysog," and at the demand of the chairman, supported by the company, an addition was made to the official programme by Dr. Frederick Roberts who sang "The Anchor's Weighed" with all the sweetness and vigour which his friends know so well, to the great delight of the gathering. At the annual meeting of the society which preceded the dinner Dr. Lloyd Owen of Birmingham was elected President, Mr. Howell Evans honorary secretary, and Mr. D. L. Thomas honorary treasurer for the ensuing year. It is hoped that as the great National Eisteddfod will be held in London in 1909 the Welsh medical gathering will be the largest which has yet assembled.

The Llanelly Hospital.—The annual meeting of the subscribers to the Llanelly Hospital was held on May 29th. The medical report was satisfactory and the financial statement showed that the institution had a favourable balance. The contributions from working men amounted to £811, and this was supplemented by £239 from the employers. The annual fête which was held last year realised £283.

West London Post-Graduate College.—The annual dinner of the Post-Graduate College and past and present members of the West London Hospital will take place at the Trocadéro Restaurant, Piccadilly Circus, W., on Tuesday, June 23rd, at 7.30 P.M. The price of the dinner ticket is 7*s.* 6*d.* (exclusive of wine), and those desirous of attending can obtain tickets for themselves or their friends by applying to Mr. Aslett Baldwin, 6, Manchester-square, London, W., the honorary secretary of the dinner. The chair will be occupied by Mr. L. A. Bidwell, surgeon to the hospital and dean of the Post-Graduate College.

Durham University Medical Graduates' Association.—The summer dinner of the southern branch of this association was held on May 29th at the Imperial Restaurant, Regent-street, London, W., when 45 members and guests were present. The President of the association, Dr. Charles W. Chapman, occupied the chair. The toast of "The University" was proposed by the Rev. George Hilton, and acknowledged by Professor Sir George Hare Philipson; and that of "The Visitors" was responded to by Mr. R. A. Robinson, chairman of the London County Council, in a delightful speech. Excellent music contributed in no small degree to the success of a very pleasant evening.

Improvements in Rome.—Mr. C. C. Morgan, the British Consul, in his annual report, just received at the Foreign Office, states that the Royal Commission appointed some time ago to study and to report upon the important question of river communication between Rome and the sea has now adopted the scheme for dredging the Tiber to a depth sufficient to allow ordinary steamers to approach Rome. Sanction has been obtained for constructing a railway line from Rome to the sea-coast, but this is not intended so much to facilitate the conveyance of goods as to provide the inhabitants with the speedy means of getting to the seaside, especially during the summer months. The proposed railway will open a hitherto abandoned tract of land and will probably encourage speculators to build a small town on the coast as a summer resort. According to the general census of 1901 the resident and fluctuating population of the Province of Rome amounted to 1,196,909 inhabitants, as against 836,764 in 1871, an increase in round figures of 360,000 within 30 years. The latest calculation in January of last year showed a total of 1,278,000, the largest increase being in the city itself, to which newcomers are constantly attracted, an unmistakeable symptom of the progressive character of the Italian capital. The number of births of British subjects in Rome in 1907 was 4 (1 girl and 3 boys) and of deaths 28 (15 females and 13 males). The need of an Anglo-American club where visitors might congregate and find all necessary comforts and facilities having been realised, a committee of British and American gentlemen have raised among themselves the necessary funds to start one in Rome and it is to be inaugurated in the autumn. A suitable apartment has been already rented in the Piazza di Spagna, a favoured locality in the heart of the town. The sanitary conditions of Rome continue to improve and its death-rate (21·2 per 1000) compares most favourably with some of the other Italian towns. Malaria is no longer the scourge of the Italian capital and the few cases recorded in the hospital returns are imported from the country, where every possible effort is being made to stamp it out by prophylactic means and by extensive use of wire nettings applied to doors and windows so as to prevent mosquitoes from entering the houses. Quinine is also being freely distributed where most needed, and a squad of competent medical men travel across the "Campagna" during the summer months fighting a regular crusade against mosquitoes and malaria.

Dr. Donald W. C. Hood, C.V.O., has been nominated as a vice-president of the Royal Institution.

Association of Scottish Medical Diplomates.—The annual dinner of this association was held on May 26th at the Waldorf Hotel, Aldwych, London. The chair was occupied by Dr. David Walsh who, in proposing "The Association," said that it was formed to promote the general and professional interests of the Scottish diplomates. The association was now four years old and there was opening to it a great field of usefulness. The association attracted its members from all sections of the profession and rendered articulate the aspirations of the Scottish medical diplomates. Mr. J. G. Fitzgerald replied to the toast and Mr. Sydney Stephenson proposed "The Visitors" in an amusing speech, which was acknowledged by Dr. L. S. McManus and Dr. H. Macnaughton-Jones. Dr. McManus in the course of his remarks said that in his experience as a Direct Representative on the General Medical Council never before in the annals of that body had their Direct Representatives been more courteously received nor their wishes more thoroughly considered than at the present time. He believed that the General Medical Council was about to take a very important step towards setting its house in order and accepting the position of standing between the medical profession and the gross quackery that was rampant in the land. The toast of "The Council and Officers" was intrusted to Mr. P. H. Parsons and was replied to by Mr. Skene Keith. The evening concluded with a speech from Dr. H. W. Fitzgerald Powell proposing "The Ladies."

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Irish Universities Bill.

The progress of the Irish Universities Bill before one of the Standing Committees of the House of Commons is slow. It has not commended itself to several Unionist Members from Ulster and they have sought to have it amended in a direction more in harmony with their views. The fears which they have expressed are concerned with ecclesiastical considerations but so far they have not carried their points. On May 27th Mr. Charles Craig proposed a constitution for the new Dublin College which would give a place on the governing body to two representatives of the Royal College of Surgeons in Ireland and to two representatives of the Royal College of Physicians of Ireland in addition to various other representatives. However, the proposal was rejected by a large majority.

Juvenile Smoking.

The portion of the Children Bill dealing with juvenile smoking has now passed through the Standing Committee of the House of Commons Before the subject was exhausted Mr. Leif Jones drew the attention of the committee to smoking mixtures containing no nicotine which were sold. On analysis they were found to contain an irritant which after persistent smoking would cause throat trouble. Mr. H. Samuel, who is in charge of the Bill, shared the apprehensions of Mr. Leif Jones that dangers would ensue if these substances were ignored by the Bill. Ultimately the provisions of the Bill were extended so as to safeguard young persons from using them.

HOUSE OF COMMONS.

Wednesday, May 27th.

Whole-time Medical Officers of Health.

Mr. Brodie asked the President of the Local Government Board to state how many whole-time medical officers of health there were in England and Wales, exclusive of London, and how many of this number came up for periodical reappointment, and whether the Board was prepared to recommend the electing authorities of those who were re-elected periodically to appoint them without reference to time.—Mr. Burns (by written answer) replied: I can only give the information desired as regards cases in which the appointment is sanctioned by the Local Government Board, and thus it does not extend to medical officers of health appointed for counties or for the majority of county boroughs. There are 104 medical officers of health for districts outside London who give their whole time to the duties of that office either by itself or in conjunction with some other appointment of a public character. Of this number 75 are subject to periodic reappointment. The officers referred to include those who act for more than one district. The total number of districts for which they act is 315. The question of the tenure of office of these officers is receiving my attention, but I may state that in suitable cases it is already the practice of the Local Government Board to recommend local authorities to appoint their medical officer of health permanently or for a lengthened period.

The Pollution of the Ballybritt.

Mr. Reddy asked the Chief Secretary to the Lord Lieutenant of Ireland to say whether the Local Government Board had received representations protesting against the pollution of the River Ballybritt in county Tipperary; whether he was aware that a large population in this district were solely dependent for their water-supply for domestic purposes on this river; and in view of the danger to the health of the people residing in this district and the damage already done to the fish in the river, whether steps would be at once taken fully to enforce the provisions of the Public Health (Ireland) Acts against the persons who were causing this nuisance and danger to their neighbours.—Mr. Birrell furnished the following reply: The Local Government Board has received complaints to the effect stated, and the local medical officer of health has reported that a number of families are dependent for water on the river in question. It appears that the pollution of the river arises from sheep dipping, and the Board has been advised that pollution of this character is not covered by any of the Acts under which the sanitary authority can proceed. It is, however, open to the persons concerned to take legal proceedings for their own protection.

Ireland and the Poisons and Pharmacy Bill.

Sir Thomas Esmonde asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that the Poisons and Pharmacy Bill did not apply to Ireland; whether he was aware that this Bill gave power to county councils in England and Scotland to issue licences to traders other than chemists to sell such articles as sheep dips, weed killers, and other poisonous substances commonly used by farmers; and whether he would see that the Bill was extended to Ireland, in view of the fact that the necessity for relaxation of the restrictions imposed by the Act of 1868 was far greater in Ireland than in Great Britain.—Mr. T. W. Russell (who replied) wrote: The joint committee has at my instance inserted a clause for the application of this Bill to Ireland.

Tuberculosis in Ireland.

Mr. Devlin asked the Chief Secretary to the Lord Lieutenant of Ireland whether he could state if the recent campaign against tuberculosis in Ireland had resulted in the diminution of that disease, and, if so, to what extent; whether any, and how many, of the local authorities had undertaken organised action to combat the disease; and whether the Government proposed to introduce legislation on the subject embodying the recommendations of the leading Irish medical specialists as to the best means of prevention and cure of the disease.—Mr. Birrell gave the following written answer: It is too soon to form an estimate of the results accruing from the measures recently taken with a view to the prevention of tuberculosis. All the sanitary authorities in the county of Cork, some of those in county Dublin, and the Belfast corporation and board of guardians have already taken steps for the provision of sanatorium accommodation, and there is reason to believe that many other counties and cities are merely awaiting the promised legislation before taking similar steps. The measure to be introduced by the Government will embody the principles which are recognised to be the most effective that can be taken by local authorities for the prevention and cure of the disease.

Thursday, May 28th.

Importations of Fresh Milk.

Answering Mr. Brigg, Mr. Churchill (President of the Board of Trade) said: In January, 1908, the average quantity of fresh milk imported daily into England was 150 gallons, in February 150 gallons, and in March 48 gallons. There were no importations in April or in May to date. The whole of this milk was imported at Southampton.

Overcrowding in Oldham.

Mr. Clynes asked the President of the Local Government Board whether his attention had been drawn to a report presented to the last meeting of the Oldham Trades and Labour Council showing that, largely on account of extensive mill building in recent years, there was a great scarcity of suitable dwelling-houses for the working classes in the Oldham district, and alleging that more than 10,000 persons lived in a condition of overcrowding, and that many insanitary evils and a higher rate of infantile mortality had thereby resulted; and whether he could take action to press upon the local authorities of the district the necessity of immediately exercising municipal powers at present unused to insure a better supply of suitable houses and the erection of other premises on more methodical and improved lines.—Mr. Burns answered: I have seen a newspaper account of a meeting of the Oldham Trades and Labour Council held within the last few days at which the report mentioned was read. I do not gather whether the report has been sent to the town council of the borough, but if not this should be done at once. I will communicate with it on the subject to which it relates. I may add that if the Housing, Town Planning, &c., Bill now before Parliament becomes law, Part III. of the Housing of the Working Classes Act, 1890, which enables local authorities to provide houses and at present is only adoptive, will be put in force throughout the country and a statutory complaint can be made to the Local Government Board if the local authorities fail to exercise their powers under that part in cases where they ought to have been exercised and the Board would then be empowered to take action.

The Report of the Belfast Health Commission.

Mr. Devlin asked the Chief Secretary to the Lord Lieutenant of Ireland whether he had any power to compel the Belfast corporation to print and publish a sufficient number of copies of the Belfast Health Commission report to meet the public demand for the same; and if so, whether he would exercise that power in view of the complaints from all quarters as to the impossibility of obtaining copies of the report; and whether, in the meantime, he would order that a copy of the report be laid upon the table of the House.—Mr. Birrell replied: 250 copies of the report in question were printed at the expense of the Belfast corporation and of these the Local Government Board had 150, nearly all of which have been distributed amongst public bodies and interested persons. The corporation has declined to incur the expense of printing additional copies and I have no power to compel it to do so. As, however, the report is of general interest from the point of view of the public health I will lay it on the table at an early date.

The Public Abattoir in Belfast.

Mr. Devlin asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that the public abattoir in Belfast was a standing menace to the health of the city; that nine years ago a new abattoir was proposed and a loan of £30,000 for its construction sanctioned by the Local Government Board; but that, notwithstanding this, the corporation had not yet decided upon a site for the new abattoir; and whether, in view of these circumstances, the Local Government Board proposed to take any action in the matter.—Mr. BIRRELL furnished the following written reply: The Belfast Health Commission has reported unfavourably upon the situation of the abattoir and the insufficiency of its accommodation. A loan for a new abattoir was sanctioned nine years ago, but up to the present the corporation has not decided upon a site. The matter is one within the discretion of the corporation and the Local Government Board has no power to compel it to provide a proper abattoir; but it may, perhaps, be anticipated that the recommendation of the Commission will induce the corporation to take action in the matter.

MONDAY, JUNE 1ST.

Ruchill Fever Hospital.

Mr. WATT asked the Secretary for Scotland whether the resident medical officers at Ruchill Fever Hospital, Glasgow, had been dismissed because they drew the attention of the Local Government Board to evils which had been fully substantiated on public inquiry; and, if so, whether he would say what steps he proposed to take in the matter. —Mr. SINCLAIR replied: The resident medical officers at Ruchill Hospital were not dismissed because they drew the attention of the Local Government Board to the evils referred to. The dismissals were agreed upon by the sub-committee on hospitals on the grounds stated in its minute of Jan. 13th. I have no power to interfere with the discretion of the local authority.

Mr. WATT asked the Secretary for Scotland whether nurses had been dismissed and threatened with dismissal from Ruchill Hospital, Glasgow, on account of their having given evidence before the Local Government Commissioners; and, if so, whether he would, in view of the public necessity that those with knowledge of the facts be not in future intimidated from giving evidence in such cases, call the attention of those under his department to the unwisdom of such action.—Mr. SINCLAIR answered: I am not aware that nurses have been dismissed and threatened with dismissal from Ruchill Hospital on account of their having given evidence before the Commissioners but I am making inquiries.

Mr. WATT further asked whether the Commissioners of the Local Government Board who inquired into the charges of mismanagement at Ruchill, Glasgow, found that the resident medical officers were in no way to blame for what occurred; whether, notwithstanding this finding, these officers had been dismissed; and, if so, whether he would take steps to recommend their reinstatement.—Mr. SINCLAIR replied: The Commissioners did not find that the resident medical officers were responsible for the irregularities that formed the subject of inquiry; they were not dismissed on account of these irregularities but on other grounds; and, as already stated in reply to a previous question, I have no power to interfere with the discretion of the local authority in the matter of their dismissal.

Mr. WATT further asked the right honourable gentleman with reference to the public inquiry by his department into the charges of overcrowding and mismanagement in Ruchill Fever Hospital, Glasgow, whether it was the duty of the Commissioners appointed for this inquiry, in finding the charges well founded, to apportion the blame among the officials responsible; if so, whom did the Commissioners find responsible; and what had been done by the Local Government Board with regard to these officials to prevent a recurrence of the evil.—Mr. SINCLAIR furnished the following answer: The Local Government Board's remit to the Commissioners was "to inquire and report to them upon the complaints of overcrowding and understaffing of Ruchill Fever Hospital and on the administration and management of the hospital." The conclusions of the Commissioners will be found in their report, which has been issued as a Stationery Office paper. The main responsibility was declared to rest on the medical superintendent, but as regards overcrowding it was shared to some extent by the medical officer of health and, as regards understaffing, by the matron. The report was sent to the local authority which has now dealt with the officials responsible.

Mr. WATT asked the Secretary for Scotland whether his attention had been called to the fact that on some days in December, 1907, there were over 800 patients in Ruchill Fever Hospital, Glasgow, although the authorised maximum allowed is only 440; whether his department had traced who brought about this overcrowding; and what arrangement had it made to see that the statutory duty of the local authority to make provision for all cases of infectious diseases was carried out without giving rise to excessive overcrowding. Mr. SINCLAIR replied: The report of the Commissioners appointed by the Local Government Board shows that on certain days there were over 800 patients in Ruchill Hospital. The majority of the patients were children and the authorised number allowed is 440 adults. The responsibility for the overcrowding is dealt with in the preceding question. It lies with the local authority to make provision for such cases and to exercise all reasonable prevision in the matter.

TUESDAY, JUNE 2ND.

Cancer Research.

Captain FABER asked the Prime Minister whether, with reference to the meeting held in Berlin on May 23rd with the object of founding an international association for the prosecution of cancer research, he would promise the assistance of this country in that direction.—Mr. ASQUITH answered: No, sir; as at present advised I am not disposed to give such a promise as the honourable member suggests. The Imperial Cancer Research Fund, which is supported by Government, is doing all it can in the encouragement of individual intercourse and exchange of material between investigators of different countries.

WEDNESDAY, JUNE 3RD.

Medical Referees.

Mr. HILLS asked the Secretary of State for the Home Department how many medical referees were appointed under the Workmen's Compensation Act prior to the Act of 1907 coming into force; how many references were referred to each such referee; how many times the county court judges had asked such medical referees to act as assessors with them or called them in to advise them as to their judgments; and had the Channel Islands, and Guernsey in particular, refused to adopt the Act.—Mr. GLADSTONE furnished the following written reply: If I understand the first part of the honourable Member's inquiry rightly, he desires to know how many medical referees have been appointed for the purposes of the Workmen's Compensation Act, 1906. The number is 343. The total number of references made to referees in the nine months from July 1st, 1907, the date on which the Act of 1906 came into force, up to March 31st last, the latest date for which figures are available, is 189. Of these references 12 were made under Section 8 of the Act, 28 under paragraph (15) of Schedule I., and 149 under paragraph (15) of Schedule II. The number of cases during the same period in which referees have been summoned to sit as assessors is 33. The States of both Jersey and Guernsey have deliberated on the question of enacting legislation for the islands on the lines of our Act of 1906, but in both cases the proposal was rejected.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ALEXANDER, F. J., M.B., C.M. Aberd., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

BERKELEY, COMYNS, M.B., B.C. Cantab., has been appointed Obstetric Physician to the Middlesex Hospital.

BONNEY, W. F. VICTOR, M.S., M.D. Lond., F.R.C.S. Eng., has been appointed Assistant Obstetric Physician to the Middlesex Hospital.

CAMPBELL, JANET M., M.D., B.S. Lond., has been appointed a Member of the Medical Department of the Board of Education.

FAIRCLOUGH, W. A., M.B., Ch.B. New Zeal., M.R.C.S., L.R.C.P., has been appointed House Physician at the Evelina Hospital for Sick Children, Southwark, S.E.

FARQUHARSON, DAVID A., M.B., C.M., F.F.P.S. Glasg., has been appointed to the Chair of Physiology in the Royal (Dick) Veterinary College, Edinburgh.

GARDINER, PETER, M.D., C.M. Glasg., D.P.H. Lond., has been appointed Medical Officer to the Camborne (Cornwall) Nursing Association.

GLENDINNING, B., M.B., B.S. Durh., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

HANNIGAN, T. H., L.R.C.S. Irel., L.K.Q.C.P. Irel., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Drumcollogher District of the county of Limerick, Ireland.

HAWKER, GEORGE POOLE DAVID, M.B., B.C. Cantab., has been appointed Medical Officer to the Exeter Dispensary.

HOLLAND, EARDLEY LANCELOT, M.D. Lond., F.R.C.S. Eng., M.R.C.P. Lond., has been appointed Assistant Physician to the City of London Lying-in Hospital.

JONES, F. EMRYS, L.M.S.S.A., has been appointed Resident Pathologist at the Birmingham General Hospital.

LEIGHTON, G. R., M.D. Edin., F.R.S.E., has been appointed Professor of Pathology and Bacteriology at the Royal (Dick) Veterinary College, Edinburgh.

LLOYD, DAVID GEORGE, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Newcastle-Emlyn Workhouse, Medical Officer and Public Vaccinator for the Cenarth District by the Newcastle-Emlyn (Carmarthenshire) Board of Guardians, and Medical Officer of Health by the Newcastle-Emlyn Rural District Council.

MONTESOLE, M. HERSCHEL, L.R.C.P. Lond., M.R.C.S., has been appointed Junior Obstetric House Physician at St. Thomas's Hospital.

RAMSAY, JEFFREY, M.B., B.S. Lond., has been appointed Junior House Surgeon at the Blackburn and East Lancashire Infirmary.

RENTON, JOHN W., M.B., Ch.B. Glasg., has been appointed Anæsthetist to the Western Infirmary, Glasgow.

ROBERTS, W. EDGAR, M.R.C.S., L.R.C.P., has been appointed Junior House Surgeon at the Macclesfield General Infirmary.

ROWNTREE, S. J., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

STEWART, A. H., M.B., M.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Queensbury District of the county of York.

THOMAS, JOSIAH TELFER, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Camborne (Cornwall) Nursing Association.

TONKING, JOHN HERBERT, M.B. Lond., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Camborne (Cornwall) Nursing Association.

WALKER, CYRIL H., M.B. Cantab., F.R.C.S. Eng., has been appointed Additional Lecturer on Ophthalmology in the Faculty of Medicine of University College, Bristol.

WILLETT, J. ABERNETHY, M.D. Oxon., M.R.C.P. Lond., M.R.C.S., has been appointed Assistant Physician to the City of London Lying-in Hospital.

WOODS, F. W., L.R.C.P. & S. Irel., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Birr District of King's County, Ireland.

WRIGHT, J. A., M.D. Cantab., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

YEARSLEY, MACLEOD, F.R.C.S. Eng., has been appointed Lecturer on Anatomy and Physiology to the Ealing Training College for Teachers of the Deaf.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Alton, Hants, Lord Mayor Treloar Cripples' Home and College.—Resident Medical Officer. Salary £150 per annum.

Aylesbury, Bucks County Lunatic Asylum, Stone.—Senior Assistant Medical Officer. Salary £175 per annum, with board and apartments.

Aylesbury, Royal Buckinghamshire Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

Bangor, Carnarvonshire and Anglesey Infirmary.—House Surgeon. Salary £100 per annum, with board, washing, and lodging.

Bath, Royal Mineral Water Hospital.—Resident Medical Officer. Salary £100 per annum, with lodging, board, and laundry.

Bexley, Kent, London County Asylum.—Junior Assistant Medical Officer, unmarried. Salary £160 per annum, with board, apartments, and washing.

Bridgwater Hospital.—House Surgeon, for six months. Salary at *rate of £80 per annum, with board, lodging, and washing.*

Bristol Royal Hospital for Sick Children and Women.—Assistant House Surgeon for six months. Salary £50 per annum, with board, rooms, and attendance.

Burton-on-Trent Infirmary.—House Surgeon. Salary £120 per annum, with rooms, board, coals, and light free.

Carmarthenshire Infirmary.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, board, attendance, &c.

Chelsea Infirmary, Cale-street, S.W.—Second Assistant Medical Officer. Salary £100 per annum, with board, washing, apartments, &c.

Cheltenham Education Committee.—Two Medical Inspectors of School Children. Salary £100 each per annum.

Chester, City of.—Assistant Medical Officer of Health. Salary £250 per annum.

City of London Hospital for Diseases of the Chest, Victoria *Park, E.—House Physician for six months. Salary at rate of £50* per annum, with board, washing, and residence.

City of London Lying in Hospital, City-road, E.C.—Honorary General Physician.

Coventry and Warwickshire Hospital.—Junior House Surgeon for six months. Salary at rate of £60 per annum, with rooms, board washing, and attendance.

Crewe, Borough of.—Medical Officer of Health. Salary £400 per annum, rising to £500.

Derby, Derbyshire Royal Infirmary.—Assistant House Surgeon for six months. Salary at rate of £60 per annum, with board, residence, and washing.

Dumfries and Galloway Royal Infirmary.—Assistant House Surgeon. Salary £55 per annum, with board and lodging.

Fulham Infirmary, St. Dunstan's-road, Hammersmith, W.—Second Assistant Medical Officer for six months. Salary at rate of £100 per annum, with board, apartments, and washing. Also Locum Tenens for two months. Salary at rate of £4 4*s.* per week, with board, apartments, and washing.

Hampstead General Hospital and North-West London Hospital.—House Physician for six months. Salary at rate of £70 per annum, with board and residence.

India, Ludhiana, Punjab.—Two Physicians (females).

Indian Medical Service.—Examination for 20 Commissions.

King Edward VII. Sanatorium, Midhurst, Sussex.—Junior Assistant Medical Officer, unmarried. Salary £100 per annum, with board, lodging, and attendance.

Leicester Infirmary.—Assistant House Physician. Salary at rate of £50 per annum, with board, apartments, and washing.

Lichfield, *County Asylum, Burntwood.—Junior Assistant Medical* Officer, unmarried. Salary £150 per annum, with board, lodging, attendance, and washing.

Liverpool Dispensaries.—Assistant Surgeon, unmarried. Salary £100 per annum, with board and apartments.

Liverpool Infectious Diseases Hospital.—Assistant Resident Medical Officer, unmarried. Salary £120 per annum, with board, washing, and lodging.

Liverpool Infirmary for Children.—House Surgeon. Salary £100 per annum, with board and lodging.

Liverpool Stanley Hospital.—Honorary Ophthalmic Surgeon. Also Junior House Surgeon. Salary £60 per annum, with board, residence, and washing.

Liverpool, University of.—Chair of Therapeutics.

London County Council.—Inspector under the Midwives Act, 1902 (female). Salary £175, rising to £300 per annum.

Maidstone, Kent County Asylum.—Fourth Assistant Medical Officer, unmarried. Salary £175 per annum, with *quarters, attendance,* washing, &c.

Manchester Eye and Ear Hospital, 25, St. John-street, Deansgate.—Medical Officers for the Examination of School Children. Also Clinical Assistants.

Manchester Royal Infirmary, Convalescent Hospital, Cheadle.—Assistant Medical Officer, unmarried, for five months. Salary at rate of £80 per annum, with board and residence.

Manchester, St. Mary's Hospitals for Women and Children.—Resident Surgical Officer. Salary £100 per annum, with board and residence.

Metropolitan Hospital, Kingsland-road, N.E.—Assistant Surgeon for Diseases of Women.

Miller General Hospital, Greenwich-road, S.E.—Physician to In-Patients. Also Surgeon to In-Patients. Also Junior House Surgeon for six months. Salary at rate of £80 per annum.

Newport and Monmouthshire Hospital.—Third Resident Medical Officer. Salary £60 per annum, with board, residence, and laundry.

Northampton, County Borough of.—Assistant Medical Officer of Health. Salary £200 per annum, rising to £250.

Norwich City Asylum, Hellesden-next-Norwich.—Assistant Medical Officer, unmarried. Salary £150, rising to £180 per annum, with rooms, board, and attendance.

Oldham, County Borough of.—Assistant Schools Medical Officer. Salary £200 per annum, rising to £260.

Poplar and Stepney Sick Asylum, Bromley, E.—Second Assistant Medical Officer. Salary £100 per annum, with rations, apartments, and washing.

Portsmouth Borough Asylum.—Assistant Medical Officer, unmarried. Salary £150, *rising to £200 per annum,* with board, lodging, and washing.

Prince of Wales's General Hospital, Tottenham, N.—Junior House Physician. Salary £40 per annum, with residence, board, and laundry.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—House Physician for six months. Salary at rate of £60 per annum, with board, residence, and laundry.

Rangoon Municipality.—Health Officer. Salary Rs.1000, *rising to* Rs.1500 per mensem.

Royal Free Hospital, Gray's Inn-road, W.C.—Junior Obstetric Assistant for six months. Board, lodging, and laundry provided. Also Clinical Assistants, all females.

Royal Waterloo Hospital for Children and Women, S.E.—Junior Resident Medical Officer. Salary at rate of £40 per annum, with board and washing.

St. Mary's Hospital, Paddington, W.—Resident Casualty House Surgeon. Also Resident Assistant Anæsthetist. Both for six months. Salary in each case at rate of £100 per annum, with board and residence.

Salford, County Borough of, Education Committee.—Assistant Medical Officer. Salary £350 per annum, rising to £500.

Shrewsbury, Salop Infirmary.—House Physician. Salary at rate of £60 per annum, with board and apartments.

Southampton, Royal South Hants and Southampton Hospital.—Junior House Surgeon for six months. Salary at rate of £60 per annum, with rooms, board, and washing.

Syria, Lebanon Hospital for the Insane, Asfuriyeh.—Medical Superintendent. Salary £300 per annum and house.

Warwickshire *County Council.*—Two Medical Inspectors of Elementary School Children. Salary in each case £250 per annum.

West-End Hospital for Diseases of the Nervous System, &c., 73, Welbeck-street, W.—Resident Medical Officer for six months, renewable. Salary at rate of 50 guineas per annum, with residence, board, washing, and attendance.

West London Hospital and Post-Graduate College, Hammersmith-road, W.—Clinical Assistants, also Casualty Officers.

Western Australia, Hospital for the Insane.—Senior Assistant Medical Officer, unmarried. Salary £380, rising to £405 per annum, with board, lodging, washing, fuel, and light. Also Junior Assistant Medical Officer. Salary £285, rising to £315 per annum, with board, lodging, washing, fuel, and light.

Western General Dispensary, Marylebone-road, N.W.—Junior House Surgeon. Salary at rate of £80 per annum, with board, residence, and washing.

Weston-super-Mare Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

Wolverhampton and Midland Counties Eye Infirmary.—House Surgeon. Salary £80 per annum, with apartments, board, and laundry.

Wolverhampton and Staffordshire General Hospital.—Resident Medical Officer. Salary £100 per annum, with board, lodging, and laundry. Also House Surgeon. Salary £80 per annum, with board, lodging, and laundry.

The Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as *Certifying Surgeon* under the Factory and Workshop Act at Downham Market, in the county of Norfolk.

Births, Marriages, and Deaths.

BIRTHS.

Barradell-Smith.—On May 24th, at London-road, South Lowestoft, the wife of S. Barradell-Smith, M.B., B.C., of a son.

Bawtree.—On May 27th, at the Lodge, Malden, Essex, the wife of Frank Bawtree, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

Beale.—On May 31st, the wife of Hanway Beale, M.D. Lond., of Retford, of a daughter.

Wilson.—On May 22nd, at Chevening-road, London, N.W., the wife of Thomas Wilson, F.R.C.S., of a son.

DEATHS.

Nunes.—On June 1st, at Llandrindod Wells, Herbert FitzStephen Nunes, L.R.C.P., M.R.C.S., in his 42nd year.

Overton.—On May 31st, suddenly, at Bradford-road North, Huddersfield, Arthur Overton, M.R.C.S., L.R.C.P., aged 46 years.

Purvis.—On May 29th, at Lansdowne-place, Blackheath, Prior Purvis, M.D. Lond., aged 95 years.

Richards.—On May 29th, at his residence, 150, West Hill, Putney, S.W., Samuel Atkinson Richards, L.R.C.P., M.R.C.S., L.S.A., in his 76th year. Interred in Norwood Cemetery.

Ridge.—On May 25th, at Carlton House, Enfield, Middlesex, John James Ridge, M.D. and M.D. (State Medicine), B.A., B.S., B.Sc. Lond., aged 61 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

WAKLEY v. MACAURA.

ON May 5th last the proprietors of this journal commenced an action against Mr. G. J. Macaura for damages sustained by them in their business as proprietors and publishers of THE LANCET by reason of the use of the name of THE LANCET without their authority and by reason of the publication by Mr. Macaura of (*a*) a poster headed "The Steel Doctor," posted on or about March 24th, 1903, on a hoarding at the corner of Edmund-street and Broad-street, Birmingham, and elsewhere in Birmingham; (*b*) a publication called "Dr. Macaura's Health Record," published on or about March 24th, 1903, in Birmingham; (*c*) a pamphlet called "The Book of Health" published on or about March 24th, 1903, in Birmingham; (*d*) two leaflets issued with the said "Book of Health," which documents contained (*inter alia*) extracts from a reference made in this journal to a certain massaging machine. There was also a claim in the alternative to the above for damages for libels contained in the said poster, publication, pamphlet, and leaflets. In addition to the above an injunction was claimed to restrain Mr. Macaura, his agents, and servants from further writing, printing, circulating, distributing, or otherwise publishing the said poster, publication, pamphlet, and leaflets or any of them and from using the name of THE LANCET without the authority of the proprietors of this journal, and from further writing, printing, circulating, distributing, or otherwise publishing the said libels or any further or other libels affecting their business as proprietors of THE LANCET.

On May 8th last, before Mr. Justice Ridley in King's Bench Judges' Chambers, Mr. Macaura by his counsel undertook that until the trial of the action he would not make use of the name of THE LANCET, and this undertaking has since by consent been made perpetual. In these circumstances the proprietors of this journal have decided not to proceed any further in the matter.

A HOSPITAL EXONERATED.

THE rules and regulations of the Royal Mineral Water Hospital at Bath have been inquired into by a coroner's jury at West Lavington in Sussex. An old man named Edmund Ellcombe, aged 72 years, had been in the hospital for the special treatment provided there. By his own request, and without making any complaint whatsoever, Ellcombe was allowed to leave the institution before the course of baths had been completed and on a day other than that specified by the rules of the institution. On the journey home, a journey necessitating many changes of trains and delays at stations, Ellcombe contracted double pneumonia, and, to his friends, complained of the treatment which he received at Bath. However, after two lengthy sittings and having heard the resident medical officer and the head nurse from Bath the jury, on May 19th, exonerated the Royal Mineral Water Hospital.

A REMARKABLE SPECIMEN.

To the Editor of THE LANCET.

SIR,—An interesting and remarkable specimen, unfortunately now too dried to be preservable, has just been presented to me by patients of mine at Boreham Wood. On breaking a hen's egg obtained from Bullbaiters Farm there they found within it a tape-worm. The worm is complete and measures about two inches in length.

I am, Sir, yours faithfully,

HENRY BAZETT.

Hendon, May 25th, 1903.

THE THERAPEUTIC APPLICATIONS OF BETA-NAPHTHOL.

IN a recent number of the *Bulletin des Sciences Pharmacologiques* M. Ed. Desesquelle contributed a useful review of the therapeutic applications of beta-naphthol. It has been given internally with success as a gastro-intestinal antiseptic but it occasionally causes gastric disturbance. On this account it is preferable to administer it with sodium bicarbonate which lessens its irritating action on the gastric mucous membrane. In this form daily doses of 45 grains of beta-naphthol have been given in enteric fever without producing ill effects. In pulmonary tuberculosis good results have been obtained by intra-pulmonary injections of an emulsion containing five grains of beta-naphthol administered once a week. In furunculosis and anthrax benefit has been derived from the internal administration of daily doses of 15 grains, the treatment being associated with a vegetarian diet, with eggs and milk (*le régime ovo-lacto-végétarien*). M. Desesquelle recommends the use of beta-naphthol as an antiseptic in obstetric and in surgical practice. In the form of a 10 per cent. ointment or solution it is valuable in the treatment of acne, eczema, psoriasis, pityriasis, and many other skin affections; it may be combined with sulphur, zinc oxide, camphor, acetic acid, or resorcin. Internally, it is compatible with the salicylates, subnitrate and benzoate of bismuth, sodium bicarbonate, the oxide and carbonate of magnesium, calcium carbonate and phosphate, vegetable charcoal, and menthol. It is incompatible with mercuric chloride, producing from aqueous solutions a precipitate containing mercury. When prescribed in the form of a dusting powder care should be taken not to combine beta-naphthol with camphor, phenol, or menthol, or a liquid product will be formed. Beta-naphthol is contra-indicated in cases of renal insufficiency and where there is a deficiency of pepsin as it is likely to cause acute nephritis. Two cases have been met with in which the application of a 2 per cent. ointment for a cutaneous affection produced albuminuria, one case proving fatal. In its antiseptic properties beta-naphthol compares favourably with mercuric chloride. Investigations of the bactericidal action of beta-naphthol on staphylococcus pyogenes aureus showed that in dilutions of 1 to 3200 growth was inhibited for 24 hours and that a 1 in 2500 solution completely arrested all development.

CHANTECLAIR.

WE have received an advertisement, entitled "Chanteclair," which is published by "La Carnine Lefrancq," a company for the sale of a beef juice which has its headquarters apparently at Romainville and 73, Faubourg St. Denis, Paris. The pamphlet is composed of brief biographical notices of Professor Charles Richet and Dr. Jules Héricourt, between which are sandwiched some 30 letters from French medical men relating the "resurrections" and "unhoped," "remarkable," and "marvelous" (*sic*) results which have been obtained by the use of "Carnine Lefrancq." The thoroughly objectionable feature, however, of what would otherwise be only the ordinary advertising circular is two caricatures of Professor Richet and Dr. Héricourt respectively, purporting to show them engaged upon their scientific work. The pictures, if not so absurd, are almost as revolting as those published by anti-vivisectionist bodies. The fact that Professor Richet and Dr. Héricourt do not consider themselves deeply wronged by these caricatures will aid the more rabid anti-vivisectionists to treat the caricatures as representations of fact. The attitude of Professor Richet and Dr. Héricourt, which is one of good-natured contempt for the ignorance of those who can be moved to any sort of feeling by such rubbish as these caricatures, is one that it is easier for French than for English men of science to maintain. The French physiologist has not the same malignant stream of calumny for ever turned upon his work.

ST. ANN'S WELL, HOVE.

THE municipal authorities of Hove are to be congratulated on having acquired for the benefit of the residents in that part of what really is the town of Brighton the old Wick chalybeate spring and grounds. It would have been a pity had this picturesque rural spot passed into builders' hands. None of the open spaces in Hove can compare with this latest acquisition; it is the only naturally-wooded spot in the borough. And this beauty spot is one of considerable historic interest. In the middle of the eighteenth century a mineral spring was discovered there and it was described in a work published by Dr. Anthony Relhan in 1761, shortly after he succeeded the famous Dr. Richard Russell as Brighton's leading physician. Some years later Dr. Henderson confirmed Dr. Relhan's opinion as to the water being a valuable specific in certain complaints, and in 1805 Dr. Alexander Marcet of Guy's Hospital issued a pamphlet in which he described the water as presenting a solution of emetic tartar and a quantity of calcareous earth mixed with vitriolic acid and iron, giving it an inky taste. It was not long before the spring was the resort of fashion, and it is on record how Queen Adelaide used to "drive up to drink the waters at the chalybeate, a sort of Spa," and Mrs. Fitzherbert writing and telling a friend of the "very essential benefit I have derived from drinking the waters of the chalybeate at the Wick, Brighton." For a time the spring seems to have lost its old prestige and it was not until about 30 years ago, when the late Dr. William Bayes of Hove contemplated establishing a "hydro" there, that there seemed a possibility of the spring becoming serviceable again. Dr. Bayes had the water analysed by the late Mr. Wanklyn of Westminster, who reported unfavourably. The source of contamination was discovered and removed and Mr. Wanklyn's second report was most favourable. But Dr. Bayes died suddenly and the project was not proceeded with further. He had, however, renamed the place St. Ann's Well—the reason for which is by no means clear—a name that remains to this day. The well-house is at present closed. The authorities have not yet had time to mature any plans for the future, but whatever may be decided upon the first step will be to insure that the water is free from contamination.

WHITSUNTIDE HOLIDAYS ON THE CONTINENT.

THE Great Eastern Railway is issuing return tickets at reduced fares to Brussels, viâ Harwich and Antwerp. Passengers leaving London in the evening reach Brussels next morning after a night's rest on board the steamer. For visiting The Hague, Scheveningen (the Dutch Brighton), and Amsterdam for the old-world cities of the Zuyder Zee special facilities are offered viâ the company's British Royal Mail Harwich-Hook of Holland route. A corridor train, with vestibuled carriages, dining and breakfast cars, is run on the Hook of Holland service between London and Harwich. From the Hook of Holland through carriages and restaurant cars are run in the North and South German express trains to Cologne, Basle, and Berlin, reaching Cologne at noon and Basle and Berlin in the evening.

T. B. U.—The scale of fees in such circumstances wants altering considerably while no uniform method of charge exists to which we can refer our correspondent. We think that the patient might well pay some small fee. The statutory fee in the Poor-law service for amputations of fingers or toes being £2, the patient would hardly consider it harsh if he were charged a guinea.

Physician.—The question of the one-portal system has been debated over and over again in our columns. The conveniences have been pointed out in much the words used by our correspondent who has, however, taken no account of the objections.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—H. Beckett-Overy, W. J. Gow): at 7.45 P.M.

Specimens:

Mr. J. D. Malcolm: (1) A Uterus with Cancer of the Cervix removed by Wertheim's method; (2) A Cystic Ovary and Hydro-salpinx removed from a Woman aged 58 years.

Dr. T. W. Eden: A Case of Bilateral Papillary Carcinoma of the Ovary.

Dr. Cuthbert Lockyer: (1) Sarcoma of the Uterus; (2) Tubal Gestation with Unusual Pathological Features.

Dr. J. F. McCann: (1) Grape-like Sarcoma of the Cervix; *(2)* Bilateral Tuberculous Salpingitis.

Short Communications:

Dr. Kedarnath Das: Gastroschisis.

Papers:

Dr. J. H. Teacher: *The Embedding and Development of a very* Young Human Ovum.

Dr. J. W. Munro Kerr: Clinical History and Microscopical Description of an Early Ovarian Pregnancy.

FRIDAY.

LARYNGOLOGICAL SECTION (Hon. Secretaries—W. Jobson Horne, H. S. Barwell): at 5 P.M.

Cases and Specimens:

Dr. Watson Williams: (1) A Case of Malignant Growth of the Septum and Naso-pharynx removed by an External Osteoplastic *Operation; (2) A Case of Laryngeal Disease for* Diagnosis; (3) Skiagrams of the Accessory Sinuses.

Dr. Herbert Tilley: (1) Specimen of a Large Post nasal Polypus removed from a Boy aged 14; (2) Spectroscope Slide showing well-marked Development of the Orbito-ethmoidal cells; (3) A Case of Subglottic Hyperplasia with considerable Narrowing of the Tracheal Air-way.

Mr. Clayton Fox: A Case of Paralysis of the Right Vocal Cord in a Man with Myopathia.

Mr. S. V. Cargill, Mr. William Turner, Dr. StClair Thomson: Orbital Cellulitis, Abscess of Left Frontal Cerebral Lobe, consequent on Acute Left Frontal Sinusitis; Operation; Cure.

Dr. StClair Thomson: (1) Radiographs of the Sphenoidal Sinus; (2) Cases of Submucous Resection of the Nasal Septum.

Mr. Stuart-Low: A Case after Operation for Angina Ludovici.

Dr. Dan McKenzie: A Case of *Malignant Disease* of the Larynx.

Dr. Jobson Horne: Preparations demonstrating the Exhibitor's Explanation of the Development of the Characteristic Appearances of Pachydermia Laryngis.

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

The Annual Meeting for the Election of Officers and Members of Council for the ensuing session will be held the same afternoon at 4 P.M.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 11, Chandos-street, Cavendish-square, W.

THURSDAY.—8 P.M., Mr. Lawford, Mr. Winfield-Roll, and others: Card Cases. 8.30 P.M., Mr. P. E. H. Adams: An Epidemic of Contagious Conjunctivitis due to the Pneumococcus. *Mr. E. Nettleship: (1)* Senile Cataract in Husband and Wife, Condition of Lenses in Children and Grandchildren; (2) Lamellar Cataract, Discoid ("Coppock") Cataract and Retinitis Pigmentosa in the same Family; (3) *A Colour-blind Family. Lieut.*-Col. H. Herbert: (1) Lower Corneal Plaques; (2) A Factor in the Production of Parenchymatous Xerosis.

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Millbank, S.W.

THURSDAY.—8.30 P.M., Lieut.-Col. H. E. Deane (R.), R.A.M.C.: A Plea for a More Detailed Study of the Soldier's Heart.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

TUESDAY.—4 P.M., Dr. H. Campbell: Clinique (Medical). 5.15 P.M., Lecture:—Dr. J. Collier: The Treatment of Neuritis.

WEDNESDAY.—4 P.M., Mr. L. Mummery: Clinique (Surgical) 5.15 P.M., Lecture: Dr. H. French: Points in connexion with *Intercurrent Medical* Illnesses during Pregnancy.

THURSDAY.—4 P.M., Mr. Hutchinson: Clinique (Surgical) 5.15 P.M., *Lecture:—Prof.* T. Hewlett: The Diagnosis of Syphilis, &c., by the Antigen Method.

FRIDAY.—4 P.M., Mr. R. Lake: Clinique (*Ear*).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-*road*, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M., *Operations.*

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Throat, Nose, and Ear Diseases. 2.30 P.M., Operations. Dr. Abraham: Skin Diseases. 5 P.M., Lecture:—Dr. Pritchard: The Diagnosis and Treatment of Arterio-sclerosis.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. K. Scott: *Diseases of the Eyes.* 2.30 P.M., Operations. Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Medicine.

THURSDAY.—2 P.M., Medical and Surgical Clinics. *X Rays. Mr.* Dunn: Diseases of the Eye. 2.30 P.M., Operations. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery.

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 12 15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical *Clinics.* X Rays. Dr. Davis: *Throat,* Nose, and Ear Diseases. 2.30 P.M., Operations. Dr. Abraham: Skin Diseases. 5 P.M., Lecture:—Dr. Abraham: Cases of Skin *Disease.*

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations on Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. *Dr. Scott:* Diseases of the Eyes. 2.30 P.M., Operations. Dr. Robinson: *Diseases* of Women.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. J. H. Evans). 2.30 P.M., Medical Out-patient (Dr. Whipham); Nose, Throat, and Ear (Mr. Carson); *X Rays. 4.30* P.M., *Medical* In-patient Clinic (Dr. Whiting).

TUESDAY.—Clinic:—10 A.M., Medical Out-patient (Dr. Auld). 2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Surgical (Mr. Edmunds); Gynæcological (Dr. Giles). 4.30 P.M., Special *Demonstration of Selected Medical Cases* (Dr. G. P. Chappel).

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. Whipham); Skin (Dr. Meachen); Eye (Mr. Brooks).

THURSDAY.—2.30 P.M., Special Demonstration of Gynæcological Operations (Dr. Giles). Clinics:—Medical Out-patient (Dr. Whiting); Surgical (Mr. Carson); *X Rays.* 3 P.M., Medical In-patient (Dr. Chappel). 4 30 P.M., Throat Operations (Mr. Carson).

FRIDAY.—10 A.M., Clinic:—Surgical Out-patient (Mr. J. H. Evans). 2.30 P.M., Surgical Operations (Mr. Edmunds). *Clinics:*—Medical Out-patient (Dr. Auld); *Eye (Mr. Brooks).* 3 P.M., Medical In-patient (Dr. R. M. Leslie).

LONDON SCHOOL OF CLINICAL MEDICINE, *Dreadnought* Hospital, Greenwich.

MONDAY.—2.15 P.M., *Sir Dyce Duckworth:* Medicine. 2.30 P.M., Operations. 3.15 P.M., Mr. W. Turner: Surgery. 4 P.M., Mr. L. A. Lawrence: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2.15 P.M., Dr. R. T. Hewlett: Medicine. 2.30 P.M., *Operations. 3.15* P.M., Mr. Carless: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2.15 P.M., Dr. F. Taylor: Medicine. 2.30 P.M., Operations. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 2 15 P.M., Special Lecture:—Dr. Taylor: Jaundice.

THURSDAY.—2.15 P.M., Dr. G. Rankin: Medicine. 2.30 P.M., Operations. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Mr. M. Davidson: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2.15 P.M., Dr. R. Bradford: Medicine. 2.30 P.M., Operations. 3.15 P.M., Mr. McGavin: Surgery. Out-patient *Demonstrations:—10* A.M., Surgical and Medical. 12 noon, Skin. 3.15 P.M., Special Lecture:—Mr. McGavin: The Radical Cure of Complete Procidentia Uteri.

SATURDAY.—2.30 P.M., Operations. Out-patient *Demonstrations:*—10 A.M., Surgical and Medical. 11 A.M., Eye.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

FRIDAY.—3.30 P.M., Lecture:—Dr. Tooth: *Multiple Neuritis.*

ROYAL INSTITUTE OF PUBLIC HEALTH, Theatre of the Institute, 37, Russell-square, W.C.

WEDNESDAY.—5 P.M., Harben Lecture:—Prof. G. H. F. Nuttall: Ticks, their Biology and Structure.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH 1, Upper Montague-Street, Russell-square, W.C.

TUESDAY.—3 P.M., Opening Meeting. Dr. J. Kerr: Address. An Exhibition of Appliances, Outfits, Record Systems, Office Requisites, &c., will be open daily from 10 A.M. to 6 P.M.

WEDNESDAY.—11 A.M., Lecture:—Dr. C. J. Thomas: Medical Inspection. 2 P.M., Visit to Schools. *5.30* P.M., *Lecture:*—Dr. Shrubsall: Anthropometry. Dr. Shrubsall: Physical Exercises.

THURSDAY.—10 30 A.M., *Dr. Kerr:* Demonstration of Special Cases. 11.30 A.M., Dr. Thomas: Office Routine, Ringworm Examination, &c. Visits to Schools. 2.30 P.M., Lecture:—Dr. Kerr: Eyes and Ears. 3.30 P.M., Lecture:—Dr. H. M. Richards: School and Home; Infectious Diseases. 5.30., P.M., Lecture:—Dr. Hogarth: School Clinics.

FRIDAY.—10.30 A.M., Dr. Kerr: Demonstration at *London* County Council Education Offices. Visits to Schools.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (8th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), West London (2.30 P.M.).

TUESDAY (9th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.).

WEDNESDAY (10th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (13th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are :—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

During the week marked copies of the following newspapers have been received:—*Leicester Daily Post, Australasian Medical Gazette, Bristol Weekly Mercury, Financial Times, Standard, Dundee Advertiser, Birmingham Post, Daily Telegraph, The Field, Westminster Gazette, Irish Independent, South Eastern Gazette, Daily Chronicle, Liverpool Post, Aberdeen Journal, Birmingham Dispatch, Yorkshire Observer, Western Mercury, Glasgow Weekly Citizen, &c.*

Communications, Letters, &c., have been received from—

A.—Dr. N. H. Alcock, Lond.; Dr. H. G. Adamson, Lond.; Admiralty Medical Department, Director-General of; A. C.; Messrs. Armour and Co., Lond.; Anglo-American Pharmaceutical Co., Croydon

B.—Dr. A. C. Bisharad, Calcutta; Mr. Thomas Bell, Uppingham; Mr. G. P. Butcher, Plymouth; Messrs. Burroughs, Wellcome, and Co., Lond.; Board of Education, Lond., Secretary of; Dr. Victor Bonney, Lond.; *Birmingham Daily Post*, Manager of; Bristol Royal Hospital for Sick Children, Secretary of; British Medical Benevolent Fund, Lond., Hon. Secretary of; Mr. John Storer Beveridge, Milnathort; Dr. H. G. Bateman, Lond.; Dr. James Buchanan, Watford; Dr. A. L. Benedict, Lond.

C.—Dr. Myer Coplans, Leeds; Dr. P. B. Considine, Linthorpe; *The Chemist and Druggist*, Lond., Publisher of; Mr. A. L. Clarke, Buckhurst Hill; Continental Tyre and Rubber Co., Lond.; Messrs. J. and A. Churchill, Lond.; Cheltenham Education Committee, Secretary of; Cheadle Royal, Cheadle, Secretary of; Crewe Corporation, Clerk to the; Dr. H. H. Clarke, Liverpool; Messrs. Cassell and Co., Lond.; Coventry and Warwickshire Hospital, Secretary of; C. F.; *Chester Courant*, Chester, Manager of; Messrs. Corbyn, Stacey, and Co., Lond.; Messrs. A. H. Cox and Co., Brighton; Messrs. Samson Clark and Co., Lond.; Chelsea Guardians, Clerk to the; Mr. F. W. Clarke, Chorlton-cum-Hardy; Dr. Donald E. Core, Derby.

D.—Mr. Percy Dunn, Lond.; Mr. G. T. De Fraine, Aylesbury; Messrs. F. Davidson and Co., Lond.; Dumfries and Galloway Royal Infirmary, Secretary of; Derbyshire Royal Infirmary, Derby, Secretary of; Messrs. Dale, Reynolds, and Co., Lond.; Messrs. Duncan, Flockhart, and Co., Edinburgh; Durham University Medical Graduates' Association, Hon. Secretary of.

E.—Dr. Wm. Ewart, Lond.; East and North Yorkshire Medical Benevolent Society, Hull, Hon. Secretary of; Evening News Co., Portsmouth, Manager of.

F.—Dr. W. Fletcher, Kuala Lumpur; Messrs. Flint and Durbridge, Lond.

G.—Dr. R. A. Glegg, Lincoln; Gt. Eastern Railway Co., Lond., Continental Traffic Manager of; Messrs. Greening and Co., Lond.; Dr. A. S. Gubb, Aix-les-Bains; Mr. H. M. W. Gray, Aberdeen; Sir W. R. Gowers, Lond.; Messrs. Grant, Taylor, and Atkinson, Lond.

H.—Mr. J. A. Horne, Blackburn; Hygienic Co., Lond.; H. L. P. H.; Mr. T. H. Hewitt, Lond.; Honolulu Association, Honolulu, Librarian of; Mr. J. Hartley, Huddersfield; Hastings Corporation, Clerk to the.

I.—Messrs. Isaacs and Co., Lond.

J.—Mr. E. B. Jones, Lond.; Mr. C. Jung, Lorch, Germany; Jenner Institute for Calf Lymph, Lond., Secretary of; Messrs. George W. Jacobs and Co., Philadelphia.

K.—Kent County Asylum, Maidstone, Clerk to the; King Edward VII. Sanatorium, Lond., Hon. Secretary of; Messrs. Kutnow and Co., Lond.; Messrs. R. A. Knight and Co., Lond.

L.—Mr. H. K. Lewis, Lond.; Mr. C. Lawrence, Lond.; Messrs. Lee and Nightingale, Liverpool; Liverpool Stanley Hospital, Hon. Secretary of; Dr. Gerald Leighton, Edinburgh; L.R.C.P.Edin.; Dr. John Love, Glasgow; London Vegetarian Association, Secretary of; Locum, Swansea.

M.—Mr. C. A. Morton, Bristol; Mr. Christopher Martin, Edgbaston; Middlesex Hospital, Lond., Secretary-Superintendent of; Messrs. Moenich and Co., Lond.; Messrs. Merryweather and Sons, Lond.; Mrs Madden, Bromley; Dr. N. F. Mishalany, Dongola; Messrs. Maple and Co., Lond.; Manchester Eye, &c., Hospital, Hon. Secretary of; Maltine Manufacturing Co., Lond.; Dr. J. D. Malcolm, Lond.; Messrs. Mabbett and Edge, Lond.; M. B.; Medical Requisites Co., Manchester; Mrs. E. B. Mitford, New Eltham; Mountain Ash Urban District Council Education Committee, Clerk to the; Manchester Royal Infirmary, Secretary of; Mr. A. Morrison, Torquay.

N.—Mr. H. B. Newham, Goodmayes; Newport Union, Monmouthshire, Clerk to the; Northampton Corporation, Clerk to the; Norwich City Asylum, Clerk to the; Mr. J. C. Needes, Lond.; Mr. H. Needes, Lond.

O.—Odol Chemical Co., Lond.; Mr. C. H. Ostrand, Gotenburg; Oldham County Borough Education Committee, Secretary of.

P.—Mr. F. G. Parsons, Lond.; Mr. D'Arcy Power, Lond.; Mr. Young J. Pentland, Edinburgh; Dr. F. S. Pitt-Taylor, Rock Ferry; Messrs. Partridge and Cooper, Lond.; Prince of Wales General Hospital, Lond., Secretary of; Messrs. Peacock and Hadley, Lond.; Mr. F. S. Palmer, Lond.

Q.—Queen Charlotte's Lying-in Hospital, Lond.

R.—Lieutenant-Colonel R. B. Roe, I.M.S., Nagpur; Messrs. E. J. Reid and Co., Lond.; Reuter's Telegram Co., Lond., Secretary of; Royal Institute of Public Health, Lond., Assistant Secretary of; Royal Sanitary Institute, Lond., Secretary of; Royal British Nurses' Association, Lond., Secretary of; Royal Buckinghamshire Hospital, Aylesbury, Secretary of; Royal College of Surgeons in Ireland, Dublin, Registrar of.

S.—Dr. G. Scheltema, Groningen; *Shrewsbury Chronicle*, Manager of; Mr. A. Steibler, Lond.; Salford Corporation, Clerk to the; Smith's Advertising Agency, Lond.; St. Mary's Hospitals, Manchester, Secretary of; Messrs. Sewell and Crowther, Lond.; Dr. J. Sömme, Mesnalien; Messrs. W. H. Smith and Son, Letchworth; Star Engineering Co., Wolverhampton; South-West London Medical Society, Hon. Secretary of; Scholastic, Clerical, &c., Association, Lond.; Dr. D. Lloyd Smith, Frodsham; Mr. W. Stuart-Low, Lond.

T.—Dr. Ernest F. Travers, Lond.

U.—Union Reklame, Lucerne.

The Milroy Lectures

ON

MELITENSIS SEPTICÆMIA

(MALTA OR MEDITERRANEAN FEVER).

Delivered before the Royal College of Physicians of London on March 5th, 10th, and 12th, 1908,

BY J. W. H. EYRE, M.D., M.S. DURH.,
D.P.H. CANTAB.,

BACTERIOLOGIST TO GUY'S HOSPITAL AND LECTURER ON BACTERIOLOGY AT GUY'S HOSPITAL MEDICAL SCHOOL; MEMBER OF THE ADVISORY BOARD OF THE MEDITERRANEAN FEVER COMMISSION.

LECTURE I.

Delivered on March 5th.

NOMENCLATURE.

MR. PRESIDENT AND GENTLEMEN,—At the very outset I feel that some apology is needed for the title which I have given to these lectures, for in the third edition of the Nomenclature of Diseases drawn up by a Committee appointed by the Royal College of Physicians of London, and published in 1897, there first appears the entry "Mediterranean Fever, synonym Malta Fever," an entry which it is mentioned in the preface has been included "in consequence more especially of representations made by officers of the Medical Department of the Army." This entry refers to the infective disease with which I am immediately concerned, and which had hitherto hidden its identity under a variety of titles, all more or less inappropriate, conferred upon it by various observers; for it is one of the features of the history of the disease, that everyone who has seriously studied it has been extremely dissatisfied with all existing titles and has promptly put forward one which he himself considers as more appropriate, and which he foolishly imagines will soon supplant all previous names. And to this vanity I have also fallen a victim. From the prevailing type of pyrexia some have designated it simple remittent or simple continued fever; from particular clinical features febris sudoralis, gastric, or bilious remittent fever; from its resemblance to enteric fever other observers have called it intermittent typhoid, recurrent typhoid, typho-malarial, or fæco-malarial fever, whilst very protracted cases were often termed Mediterranean phthisis. Other names, identifying the disease with certain localities in which it was prevalent, were Cretan, Cyprus, Gibraltar or "Rock," Malta, Mediterranean, and Neapolitan fevers, while Tommy Atkins, the principal sufferer from the ravages of the disease, has long ago labelled it "slow continued fever." In the fourth edition (1906) of the Nomenclature of Diseases the name and its synonym are found transposed and the name of the island upon which the discovery of the specific organism of the disease was made becomes the principal part of its official designation, to the no small annoyance of the inhabitants who, and with some justice, consider that an undeserved stigma is thereby attached to their native land. Veale in 1879 recognised the erroneous impression that was created by referring to it as Malta fever and suggested that it should be called febris complicata; then, in 1897 Hughes, who had the interests of Malta closely at heart, advocated the use of the name undulant fever as indicating the general characters of the temperature in cases of the disease, but this term has never met with general acceptance. Italian observers have recently applied the title "septicæmia of Bruce" and last year Tramousti suggested the general adoption of the name. This is a step in the right direction, but in my humble opinion, and I make the suggestion with much trepidation, "micrococcus Melitensis septicæmia," or shortly "Melitensis septicæmia," is a more suitable appellation, in that it indicates both the nature of the disease and the specific infective agent. Moreover, it follows the present-day tendency to amplify the information contained in the term septicæmia—that naked term which in the old days of empirical medicine included a multitude of pathological conditions and only justified its existence by serving as a cloak for sins of inadequate and inexact diagnosis—in every case by the addition of the name of the specific microbe responsible for the infection.

The careful study of this disease appeals to us not only as medical men but as members of a great empire, while its importance cannot be gainsaid. It has during the past few years been the custom to generalise and to say that this one disease alone is responsible for a total loss to the combined army and navy on the Mediterranean station of at least 75,000 days' sickness per annum. I do not wish to labour this point—I would merely draw your attention to the accompanying table, which shows the number of cases and the mortality occurring in the Maltese civil population, in the land forces garrisoning the island, and in that portion of our navy which makes Malta its headquarters, during the years 1901–1907.

TABLE I.—*Cases of Melitensis Septicæmia and Mortality in Civil Population, and in the Navy and the Army during the Period 1901–1907 in Malta.*

—	Civil.		Navy.		Army.	
	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.
1901	642	54	252	3	253	9
1902	624	45	354	2	155	6
1903	539	48	339	6	404	9
1904	575	59	333	8	320	12
1905	663	83	270	7	643	16
1906	822	117	145	4	163	2
1907	714	78	12	0	9	1
—	4527	489	1705	30	1947	55

In bringing this instance before you I may perhaps be accused of fostering the impression that Malta is the only habitat of the disease and thereby adducing evidence justifying the nomenclature I endeavour to displace. But I would point out that my own experience of the acute phases of the disease and much of my research work on the etiology of micrococcus Melitensis septicæmia is derived from observations carried out in that island, and that I naturally prefer to draw upon my own experience and upon that of my colleagues upon the Mediterranean Fever Commission, the bulk of which I am personally acquainted with, for any illustrations that may be necessary.

HISTORICAL SUMMARY.

The disease itself may be defined as follows:—

Micrococcus Melitensis septicæmia.—A specific septicæmia, resulting, as its name implies, from infection by the micrococcus Melitensis, widely distributed throughout the subtropics. Endemic in certain localities; running an acute, subacute or chronic course of indefinite duration, often lasting for months or even years, and characterised by lack of constant symptoms other than slight or severe pyrexia—continuous, intermittent, or remittent—and a marked tendency to repeated relapses, during which the symptoms originally present may recur without alteration or diminution of severity; accompanied or followed by such toxic symptoms as neuritis or such metastases as synovitis and orchitis.

Micrococcus Melitensis septicæmia under a variety of names has apparently been known and studied from very early times, for Hippocrates is obviously describing it when he tersely says: "3. In the course of the summer and autumn many fevers of the continual type, but not violent; ...... they were affected with fevers, rigors and deficient sweats, with varied and irregular paroxysms, in general not intermitting ...... the earliest crisis which occurred was about the twentieth day, and in many about the eightieth. But there were cases in which it did not leave them thus at all, but in an irregular manner, and without any crisis; in most of these the fever after a brief interval relapsed again, and from these relapses they came to a crisis in the same periods; but in many they were prolonged so that the disease was not gone at the approach of the winter. Of all those which are described under this constitution the phthisical diseases alone were of a fatal character, for in all the others the patients bore up well and did not die of those fevers." Galen in his Commentary explains the use of the term continual as applied to these fevers by saying that such fevers as have an exacerbation ending in complete apyrexia are called intermittents, whereas such as do not end in a complete remission of the fever are called continual. Hippocrates, moreover (Epidem., lib. iii., Section III., Constitution 2),

No. 4424.

describes a case of 120-day fever, terminating fatally, in these words:—

CASE I.—In Thasus, the Parian who lodged above the Temple of Diana, was seized with an acute fever, at first of a continual and ardent type; thirsty, inclined to be comatose at first, and afterwards troubled with insomnolency; bowels disordered at the beginning, urine thin. On the sixth day passed oily urine; was delirious. On the seventh, all the symptoms were exacerbated; had no sleep, but the urine of the same characters and the understanding disordered; alvine dejections bilious and fatty. On the eighth, a slight epistaxis; small vomiting of verdigris-green matters; slept a little. On the ninth, in the same state. On the tenth, all the symptoms gave way. On the eleventh, he sweated, but not over the whole body; he became cold, but immediately recovered his heat again. On the fourteenth, acute fever; discharges bilious thin, and copious; substances floating in the urine; he became incoherent. On the seventeenth, in a painful state, for he had no sleep, and the fever was more intense. On the twentieth, sweated all over; apyrexia, dejections bilious; aversion to food, comatose. On the twenty-fourth had a relapse. On the thirty fourth, apyrexia; bowels not confined, and he again recovered his heat. Fortieth, apyrexia, bowels confined for no long time, aversion to food; had again slight symptoms of fever and throughout in an irregular form; apyrexia at times and at others not; for if the fever intermitted and was alleviated for a little it immediately relapsed again; he used much and improper food; sleep bad; about the time of the relapse he was delirious; passed thick urine at that time, but troubled and of bad characters; bowels at first confined, and again loose; slight fevers of a continual type; discharges copious and thin. On the hundred and twentieth day he died. In this patient the bowels were constantly from the first either loose, with bilious, liquid, and copious dejections, or constipated with hot and undigested fæces; the urine throughout bad; for the most part coma or insomnolence with pain; continued aversion to food. Ardent fever. *Explanation of the characters.* It is probable that the weakness produced by the fever, the phrenitis, and affection of the hypochondrium caused death on the hundred and twentieth day.

Hippocrates records another case of similar duration which followed its usual course and terminated in recovery. These cases, read in the light of our twentieth century knowledge, must undoubtedly have been cases of micrococcus Melitensis septicæmia; indeed, in the Sydenham Society's translation of Hippocrates's works published in 1849, Adams remarks of the former that "this is an example of one of those protracted fevers which, as I have been informed by an intelligent physician who practised for several years in the Ionian Islands, are so common in the climate of Greece." In another place, referring to certain of the fevers described by his author, Adams states that a careful study of modern authorities convinced him that these fevers "are exactly the same as those which are now described as still prevailing in the land of Greece and correspond very well with those described by Cleghorn (as occurring in Minorca)." Cleghorn himself (1750), Veale (1879), and Hughes (1897) are all in turn struck by the applicability of these descriptions to the disease as it manifested itself in their days, and so set the example of quoting Hippocrates which I have now followed.

From the first to the nineteenth centuries descriptive accounts of any subtropical fever which can be identified with the one under discussion are extremely rare. Some of those described by Bates in the first decade of the eighteenth century probably belong to this category as does the *febbre subcontinua* of Torti a few years later.

Hughes, who, assisted by Zammit, made a careful research through the Bibliotheca of Valetta, a library which is particularly rich in rare, and in many cases unique, manuscripts, records the fact that Bonamici (1626–1680) described a fungus indigenous to Malta—Fungus Melitensis (Cynomorium coccineum Balanophoraceæ, order Rhizanthal), which was held to be a sovereign remedy for the "fever" and a valuable monopoly of the Grand Masters—a fact which was considered of sufficient importance and interest to be reiterated in 1805 by Louis de Boisgelin; he also states that Demarco (1722–1787) refers to the occurrence of continued and remittent fevers in Malta. Howard in "Lazaretos of Europe (1786)," too, describes a low form of fever prevalent in the wards of the Great Hospital of the Knights of St. John.

Cleghorn, surgeon to the 22nd Regiment of Foot, writing of the "epidemical diseases in Minorca during the period 1744–1749" states: "Yet I have seen every year a few [cases of fever] of the continual kind; ...... some of them have continued without any considerable Interval for six or seven Weeks. Hippocrates has accurately described such." The administration of "bark" produced no effect in these cases and he further says: "...... nor could I ever fall upon any certain Method of preventing one Relapse after another until the cold Weather which commonly sets about *Christmas*, had braced the Solids and given them sufficient Strength to throw off the excrementations Humours by the proper Outlets." Incidentally Cleghorn remarks that the island abounds with goats, which "are fattened in Autumn and are slaughtered from September to January chiefly for the use of the common people." Fauverage (1803) and Robert, military surgeons to the French troops during their occupation of Malta (1798–1800), also mention "the bilious maladies, the intermittent fevers, &c., affect most especially the inhabitants of Malta."

The next author of importance to treat of the disease is Burnett (1814), in a volume which bore for its main title the words "Mediterranean Fever," followed on the next page by a lengthy descriptive title commencing "A Practical Account of the Fever commonly called the Bilious Remittent as it appeared in the Ships and Hospitals of the Mediterranean Fleet ...... and of the Gibraltar and Carthagena Fevers." This author describes the onset of the disease clearly and fully, mentions the pains in the joints, the throbbing of the carotids, the swelling of the parotids, and the petechiæ which occur during the course of the disease, and in a footnote makes the significant statement that the "patients were constantly relapsing." Burnett describes his numerous cases so clearly that the present-day student can readily pick out those of Melitensis septicæmia and distinguish them from those of typhus, typhoid, and yellow fever, yet in the preface this author states his opinion that the fevers he treats of are all identical and that copious venesection forms the only treatment.

Other military and naval surgeons—Irvine, Hennen, Burns, Baxter, Clark, and Davy—in turn took up the study of the fevers met with in the Mediterranean and a perusal of their writings leaves no shadow of doubt that Melitensis septicæmia was prevalent in both services, although there is equally no doubt that all the authors to whom reference has so far been made frequently confused it with enteric fever on the one hand and malaria on the other.

Parliamentary returns of the diseases of the navy and army during the first half of the nineteenth century bear internal evidence in those sections dealing with the Mediterranean Station of the prevalence of micrococcus Melitensis septicæmia under such headings as "remittent fever," "billious remittent," "common continued," &c., but it is not until 1863 that we find in the belated report of Marston an accurate account of the clinical symptoms which enabled him to differentiate micrococcus Melitensis septicæmia, or, as he called it, "Mediterranean remittent" or "gastric remittent," from the other fevers of the Mediterranean, including simple continued or ephemeral fever—a three- to five-day fever which he refers to as *febricula* or Maltese fever. He defines the Mediterranean remittent as "a fever characterised by the following symptoms and course: a preliminary stage of subacute dyspepsia, anorexia, nausea, headache, feeling of weakness, lassitude, and inaptitude for exertion, mental or physical, chills, muscular pains; lastly, a fever having a very long course—three to five or ten weeks—marked by irregular exacerbations and remissions, great derangement of the assimilative organs, tenderness in the epigastric region, splenic enlargement, slight jaundice without any exanthem. ...... The patient is prone to relapses and the disorder is followed by a protracted convalescence and a chloro-anæmic aspect; very frequently also by rheumatism of some form or other. The skin ...... at another time (night) is covered with perspiration, sour smelling and acid to litmus. ...... From first to last there is great depression of spirits. ...... The occurrence of wintry or cold weather acts most beneficially. ...... The tendency of the disease is decidedly to recovery—a fatal issue being very rare indeed." Further on Marston states that the rheumatism of the convalescent stage takes one or other of the following forms: (1) sciatica; (2) rheumatic orchitis (only one case suppurated); (3) general rheumatism; or (4) intercostal neuralgia.

Veale, the assistant professor of military medicine at Netley, contributed in 1879 a very complete account of the clinical symptoms presented by patients suffering from the disease when invalided home from Cyprus, Malta, and Gibraltar, together with observations upon the morbid anatomy of the affection. He lays particular stress upon the frequency with which rheumatic sequelæ occurred in invalids from Malta and Gibraltar and from this fact contends that the bulk of the fevers contracted in Cyprus were not identical with the fever so common in Malta and Gibraltar.

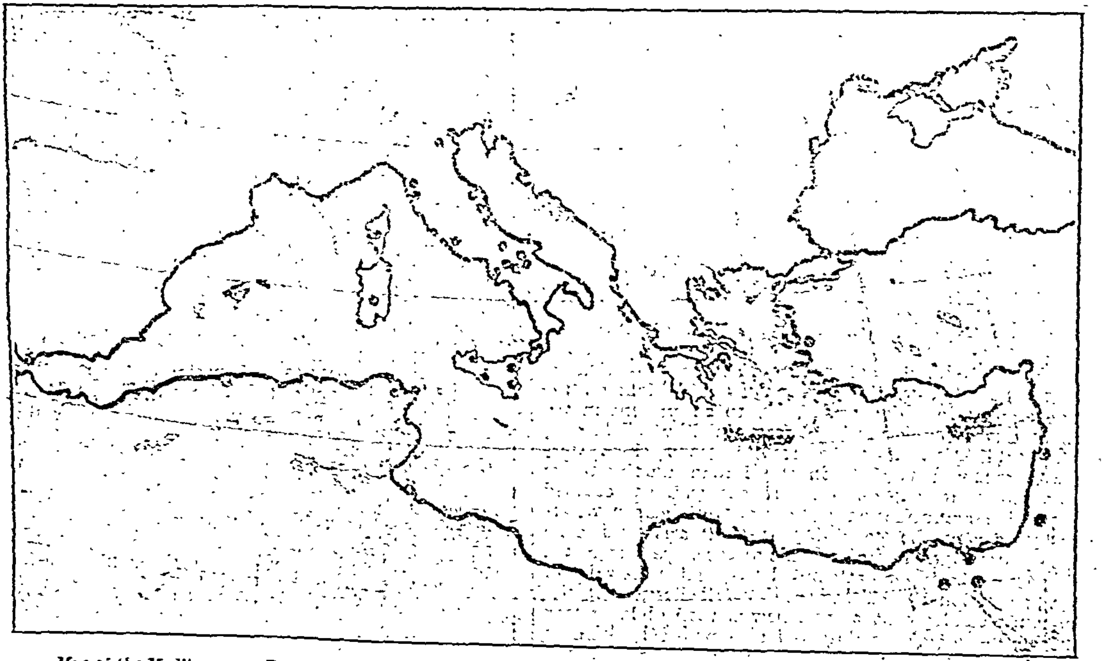
In the same year Fazeo described the disease as it occurred in Naples to the Association of Medical Men and Naturalists, and in pointing out its specific characters suggested the probability of the *causa causans* of the disease being a micrococcus or some allied microbe.

In 1886 Bruce, as a surgeon-captain in the Army Medical Staff and while stationed at Malta, first observed the specific micro-organism which is the causative factor in the production of micrococcus Melitensis septicæmia; and although in those days bacteriology was a comparatively juvenile science, he applied its principles to his investigations and early noted the presence of minute cocci in fresh preparations of the spleen pulp. In the following year he isolated and described the micrococcus and by experiment upon the monkey proved its etiological importance.

In those days the Army Medical Department did not see the wisdom of providing facilities for its officers for research work, and Bruce accordingly associated himself with Scicluna, the Government analyst, in whose laboratory the cultivation and inoculation experiments were carried out. The organism was isolated from the spleen pulp of several fatal cases and was found to fulfil the postulates of Koch. Bruce described his experiments in a preliminary note in the *Practitioner* for September, 1887, and in his next paper, contributed to the *Annales de l'Institut Pasteur*, he described his experiments in full, and by a chain of incontrovertible evidence established the specificity of the organisms he had isolated.

Bruce did not write at any great length upon the purely clinical aspects of the disease, but some ten years later Hughes (when also stationed at Malta) stimulated by the example and advice of Bruce, devoted himself to this aspect of the subject, and having amplified and confirmed the experiments of his teacher produced a monograph on the subject which from the clinical side ranks as the classic. Immediately previous to the publication of Hughes's work Wright, then professor of pathology in the Army Medical School at Netley, took up with his pupils the investigation of the disease and soon showed experimentally that specific agglutinins were present at some period or other during the course of the experiments in the blood of infected and immunised animals which were comparable to those already described by Durham, Gruber, and Widal in connexion with cholera and enteric fever. It was further shown that similar agglutinins could be demonstrated in the serum of patients who had acquired the disease naturally, whilst as they were absent from the serum of patients suffering from other diseases as well as from the serum of the normal individual their detection formed a reliable means of diagnosis. These observations upon the specific agglutinins of micrococcus Melitensis septicæmia—affording as they did an accurate basis for the differential diagnosis of obscure fevers—were eagerly applied by many observers. But it was probably nearly the end of 1900 before the agglutination test in one or other of its forms was being generally applied by both naval and military surgeons. Hence in the compilation of statistics—that is, where accuracy of diagnosis is a very essential detail—it is advisable to use only such as are available from 1901 onwards.

FIG. 1.



Map of the Mediterranean Basin indicating by black areas and spots those localities where septicæmia Melitensis is endemic.

GEOGRAPHICAL DISTRIBUTION.

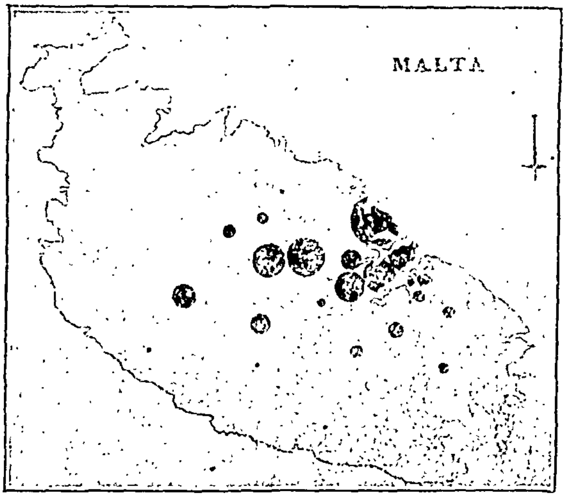
Unfortunately after Bruce had left the Mediterranean his exact researches provoked very little interest amongst the bulk of those whose duties brought them into close clinical touch with the disease. But, as I have already mentioned, the observations of Wright, providing as they did a ready means of diagnosis, were eagerly applied, and for many years the only direct advances made in the study of Melitensis septicæmia were those bearing upon its geographical distribution, for from all parts of the tropical and subtropical zones sporadic cases and small epidemics were recorded, showing most conclusively that although the Mediterranean was a perfect hot-bed of the disease many others of our possessions beyond the seas shared the unenviable distinction of harbouring this fever. Hughes, when discussing the distribution of the fever, remarked upon the fact that north of latitude 46° N., which corresponds roughly with isotherm 55° F., this fever does not exist except as imported cases. South of this line the fever is met with as an endemic disease with an increasing annual prevalence as the mean annual temperature rises above 60° F.

Shaw, in a paper communicated to the Royal Institute of Public Health at its London congress in 1905, maintained that the fever was infrequent and rare elsewhere than in Malta, and to put it plainly only occurred in such localities as were in direct sea communication with Malta.

So far as concerns the Mediterranean area, however, the evidence of the almost universal distribution of the disease is fairly complete. At Gibraltar the disease was well known until its disappearance from the Rock a few years ago. In Algiers the researches of Brault, Soulié, and Sergent, and in Tunis of Hayat, Nicholle, Schoull, and Cathoire have placed the existence of the fever beyond doubt. Manoussos, Brussis, and Thomopoulos record cases from Greece; Kaller from Smyrna; Ross from Port Said; Carbone, Gabbi, Trambusti, and others from Sicily, and practically the whole of Southern Italy, and so on, and the cases recorded are supported not merely by clinical evidence but also by the agglutination reaction and by the isolation of the specific micrococcus, either from the peripheral blood during the progress of the disease or by its recovery from various organs after death, and in some instances from both these situations. Zardi, Tiberti, and Oatani junior, on similar evidence prove its existence in Tuscany; Gabbi also notes its presence in Leghorn and Ancona, and Brunner in Trieste.

In Malta itself it was customary at one time to deny that the disease existed elsewhere than in the immediate neighbourhood of the Grand Harbour, and that it was rare to meet it except in Valetta. This spot-map of Malta that I have prepared shows not only that it is found throughout the whole of the inhabited portion of the island for every village is represented by a "spot" but that some of the inland villages present as many cases as Valetta itself or even more, for the "spots" are graduated in size to indicate the average numbers of cases per annum; thus Valetta averages 48 cases every year and Mellieha two.

FIG. 2.



Spot map of Malta showing incidence of septicæmia Melitensis.

Turning to India the existence of Melitensis septicæmia was first indicated by the observations of Wright on the specific agglutinin which was found to be present in th serum of certain cases invalided from Subathu. Following on the publication of these results many cases were reported from various spots in the Indian Empire where the diagnosis rested on clinical observations coupled with positive agglutination reactions. But many writers refused to accept the possibility of Melitensis septicæmia existing, particularly as an endemic disease, apart from the Mediterranean basin, and attempted to question the value of the serum reaction by pointing out the fallacies that at first attended the employment of this new method of laboratory investigation—fallacies mainly due to a non-recognition of the precautions which must necessarily be observed in the application of any test, and for a while it was the fashion to deny that Melitensis septicæmia had any place among the indigenous diseases of India. Evidence steadily accumulated, however. Finally, in 1905 Lamb, of the Indian Medical Service, and Kesava Pai investigated in a most comprehensive manner an epidemic of the disease at Ferozepore, during which the specific micrococcus was recovered from various patients and the accuracy of the diagnosis conclusively established, while Forster tracked down the source of infection. Recently Brayne has investigated an epidemic of Melitensis septicæmia occurring in the 36th Sikh Regiment in Rawalpindi, when the clinical diagnosis was supported by the serum reactions, and although no attempts were made to isolate the specific coccus, incontrovertible evidence was adduced by Fox to show that the regiment was being supplied with infected and infective food; and still more recently Mills of the 22nd Punjabis writes me from Jhelum saying that there are cases there in one of which micrococcus Melitensis has been recovered in pure culture from the peripheral blood.

Still further East, Bishop, who himself suffered from the disease, states that it is endemic in Hong-Kong and Shanghai. My late friend and colleague Washbourn on his return from South Africa early in 1901, expressed to me his conviction that Melitensis septicæmia existed in South Africa—in Kimberley (diagnosed as camp fever) and elsewhere—his opinion being based upon the results of agglutination reactions carried out early in 1900 where the serum had been tested against a vigorous and virulent strain of micrococcus Melitensis I had provided him with; but as none of the cases had proved fatal, the urgency of his routine work had prevented any attempt to isolate the coccus.[1] My knowledge of the disease in South Africa and its distribution there is derived from (in addition to official records) the papers published by Strachan and from private letters I have received from him, from Dr. W. W. Stoney, and from Major J. G. McNaught, R.A.M.C., to all of whom I am deeply indebted for many details. From these correspondents I gather that Melitensis septicæmia is widely diffused throughout the Transvaal, British Bechuanaland, Orange River Colony, Basutoland, and Cape Colony, as will be seen from the accompanying spot map of South Africa prepared from information supplied by the gentlemen I have just named.

Two sporadic cases have also been recorded as occurring in England in addition to several authenticated cases of laboratory infection. Of these the one mentioned by Birt and Lamb in THE LANCET of Sept. 9th, 1899, if in verity a case of Melitensis septicæmia, of which fact there does not appear to be any overwhelming evidence, might well have been a laboratory case. The second, recorded by Mangin in the same year in a young gunner who had never been out of England, would from the general course of the disease and the naked-eye appearances at the necropsy suggest chronic streptococcic septicæmia quite as much as Melitensis septicæmia.

Many cases have been recorded of individuals who have contracted the disease within some endemic area and there suffered from an indefinite malaise, so slight as to cause but little inconvenience, of a day or two's duration, and on their return to England weeks or even months later developed a severe attack of the septicæmia. These cases are frequently quoted as evidence of the lengthy incubation period of the disease.

The various localities in which Melitensis septicæmia has been conclusively proved to exist as an endemic disease may then be tabulated as follows:—

Europe.

Austria (Trieste).
Grecian Archipelago.—Athens, Nauplia, Platæa, Cephalonia (Argostolia), Corfu, Crete.
Italy.—Ancona, Benevento, Campobasso, Casserta, Cittanova, Fermo, Leghorn, Naples, Padua, Pisa, Rome, Terano.
Mediterranean Sea.—Balearic Isles (Mahon), Candia, Corsica (Ajaccio), Cyprus, Gozo, Malta, Sardinia, Sicily (Catania, Messina, Palermo, Syracuse).
Spain.—Gibraltar.
Turkey.—Constantinople, Salonika.

Asia.

Arabia.—Aden.
Asia Minor.—Beyrout, Jerusalem, Smyrna.
Assam.—Tezpur.
China.—Hong-Kong, Shanghai.
India.—Agra, Allahabad, Bombay, Calcutta, Delhi, Ferozepore, Jalandhar, Jhelum, Lucknow, Meenmer, Multan, Nowshera, Rawalpindi, Secunderabad, Simla, Subathu, Swat Valley.

Africa.

Algeria.—Algiers.
Tunis.—Cape Bon, Goulletta, Tunis.
Egypt.—Alexandria, Cairo, Massowah, Port Said, Suakin.

South Africa.

Basutoland—Leribe, Maseru, Mohalieshoek.
Cape Colony.—Barkly West, Beaufort West, Clanwilliam, Griquatown, Hanover, Hopetown, Kenhardt, Kimberley, Murraysburg, Pearston, Petrusville, Prieska, Richmond, Somerset East, Upington.
Native Provinces.—Hay, Maclear, Mount Fletcher, Ugie.
Orange River Colony.—Bethulie, Boshof, Fauresmith, Ficksburg, Koffyfontein, Luckhoff, Philipolis, Reddersburg, Senekal, Springfontein, Vrede, Wepener.
Transvaal.—Barberton, Boksburg, Dordrecht, Johannesburg.

America.

North America.—Mississippi Valley.
South America.—Brazil, Venezuela, Montevideo.
West Indies.—Cuba, Porto Rico.
Pacific Ocean.—Fiji Islands, Philippine Islands (Manila).
Atlantic Ocean.—Canary Islands.

[The lecturer proceeded to consider the etiological factors of the disease, reviewing the old opinions which held it due to "the influence of marsh miasma," or its first-cousin

---

[1] See also Brit. Med. Jour., Sept. 14th, 1901, p. 701 (Pathological Notes from South Africa, pp. 699-701).

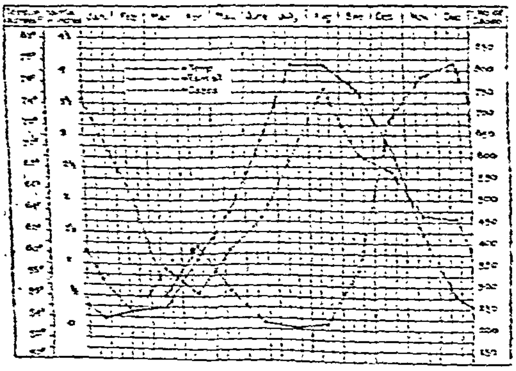
"the constant breathing of a fæcally polluted atmosphere," as stated by Burnett in 1814, and the later theories which would have it a dirt disease, and especially due to imperfect drainage. He stated that in 1905 Davies, after surveying the incidence of the disease amongst the Malta garrison, considered that the data available were insufficient to justify any absolute and definite conclusions upon the subject." He continued:]

I now propose to deal very briefly and without comment at this stage with certain etiological data—observed facts—bearing upon the incidence of the disease in relation to such factors as age, status, seasonal prevalence, atmospheric temperature, &c. For reasons already given all my illustrations in this connexion are drawn from one particular endemic area—viz., the island of Malta—and I may remark that I have drawn largely upon the epidemiological portions of the reports of the Mediterranean Fever Commission, supplemented by the official publications of the public health department of Malta, for the material for this section.

SEASONAL PREVALENCE.

The climatic conditions prevailing in Malta enable one to make the general statement that the year is divisible into a hot dry season from April to September, and a cold wet season from October to March. Again, speaking generally, the average incidence rate is lowest during the wet period from November to January, rises slowly and gradually during February to April, more rapidly during May and June and reaches its maximum during the very hot dry months of July, August, and September, months which, it may also be remarked, correspond to the greatest prevalence of insect life and also of dust. So that in general terms a very close correspondence is to be observed between the curves recording atmospheric temperature and incidence rate, and a direct opposition between those representing incidence rate and rainfall, which is well seen in the chart drawn up by Johnstone in 1904 from civil statistics (Fig. 3). At the same time it must be noted that cases occur throughout the entire year, and in examining figures for individual months in preparing yearly averages, &c., it is seen that the incidence is markedly irregular, and that often a large number of cases will appear in cold rainy months—e g., December or January, as for example in the military statistics for the period 1901–1906.

FIG. 3.



Relation of incidence rate to temperature and rainfall (Johnstone).

GENERAL SANITARY CONDITIONS.

The towns and villages in Malta can be grouped under three headings so far as general sanitation is concerned—viz., 1. An urban drained area comprising Valetta, Floriana, and the three fortified cities Cospicua, Vittoriosa, and Senglea, towns which are drained, paved, and scavenged. 2. A suburban partially drained area comprising Sliema (sewered 1902), St. Julian (1903), Hamrun, Misida and Pieta (1903). Birchircara, Curmi, Zabbar, Tarxien and Paola. 3. A rural area comprising Notabile and Rabato, Dingli, Zebbug, Siggeui, Lia, Attard and Balzan, Naxaro, Musta, Gargur, Mellieha, Lucca, Zurrico, Safi, Crendi, Micabiba, Chircop, Zeitun, Axiak, and Gudia. The combined population of each of these three areas is practically the same, but the incidence-rate per 1000 for 1904–1906 shows that the disease is most prevalent in the suburban area and least prevalent in the urban area, while in the rural area the incidence practically corresponds to the average for the whole island, which is 3·85.

Urban area, 61,242	2·99
Suburban area, 59,677	5·03
Rural area	3·61

According to Johnstone, disregarding the urban area, the greater the aggregation of inhabitants living in one locality the greater is the proportional number of cases that occur amongst them; also to a certain though less marked extent severity of incidence depends on density of population.

Length of residence in endemic area.—Malta.—The duration of residence—the length of service—in Malta of those adults who are not natives of the island is closely connected with the incidence rate, the newcomers during their first year in Malta yielding by far the largest number of cases. After the first year of residence the incidence gradually decreases until the fifth year, after which it again rises, to suffer a second fall when the period of residence has been prolonged beyond ten years.

TABLE II.—*Length of Service in Relation to Melitensis Septicæmia (Army in Malta).*

Length of service.	Aggregate strength. 1902–1906.	Notified cases.		Deaths.
		Total.	Ratio per 1000.	
Under 1 year ...	17 820	839	47·0	14
1 to 2 years ...	11,356	454	39·9	12
2 " 3 "	4,016	140	34·8	8
3 " 4 "	1,197	41	34·2	4
4 " 5 "	712	14	19·6	—
5 " 10 "	657	32	48·7	2
10 years and over	187	2	10·7	1

Age and sex.—A consideration of the statistics of the civil population for the year 1905 (when the figures in this connexion were first available) and 1906 shows that the disease is most prevalent between the ages of 11 and 30 years, though no age is immune, for I have seen a case of micrococcus Melitensis septicæmia in a woman who I was told was turned 86 years—and looked it—and I have seen another in an infant but a few days old. From civilian statistics sex would appear to be an indifferent factor. The above total of 1462 cases is made up of 750 males and 712 females, while the total population at the last census (1901) comprised 91,994 males and 92,748 females. On the other hand, military statistics would indicate that women are more than twice as susceptible as the rank and file, being 88·2 per 1000 as compared with 41·1, the mortality rates corresponding directly with the incidence rates, although there is sufficient general agreement between civil and military statistics with regard to the age-incidence of the disease.

TABLE III.—*Incidence of Melitensis Septicæmia in Relation to Age and Sex (Civil Population).*

Age—years.	Males.		Females.	
	Population.	Cases.	Population.	Cases.
0–10	19,762	62	19,105	64
11–20	16,334	173	16,336	153
21–30	13,324	221	13,227	189
31–40	10,257	117	10,412	107
41–50	9,042	76	9,224	85
51–60	6 818	59	6,842	62
61–70	3 991	33	4,183	18
71–80	2,082	7	2,190	3
81–90	723	2	729	1
Totals	82,303	750	82,254	712

TABLE IV.—*Age in Relation to Melitensis Septicæmia (Army in Malta).*

Age—years.	Aggregate strength 1902–1905.	Notified cases.		Deaths.
		Total.	Ratio per 1000.	
Under 20	4,827	190	39·3	4
20-25	14,774	811	54·9	13
25-30	7,423	233	31·3	7
30-35	4,205	125	29·7	9
35-40	3,871	120	31·0	5
40 and over ...	845	43	50·9	3

Social status.—Exact statistics bearing upon this point in relation to the civil population of Malta are not obtainable but it is a widely spread impression that the upper leisured classes are much more prone to contract the disease than the lower and labouring classes. Maltese physicians support this impression which receives some confirmation from the fact that the combined suburbs of Sliema and St. Julian, the most fashionable and wealthiest locality of the island, have by far the heaviest average case incidence—viz., 74 per 10,000 inhabitants—but personally I am not altogether convinced of the truth of the statement, for my own experience leads me to believe that the Maltese peasant when suffering from the disease, so long as he is not absolutely incapacitated, will prefer to work during the early hours of the day before his temperature rises to an inconvenient height and rest during the post meridian hours rather than call in a medical man. Consequently severe cases alone are seen by the physician and notified, a fact which goes far to explain the high case mortality of Melitensis septicæmia noted in the civil population of Malta as compared with that observed in the navy and army. In one small holding or allotment which I inspected the peasant farmer and two of his children were suffering from Melitensis septicæmia, none of them were notified and none of them were even under medical observation. Statistics from the military records, however, show clearly that the officer has a much greater liability to attack than the men, although the disease is much less fatal in the officer.

Occupation.—Statistics dealing with the relationship existing between occupation and the incidence of Melitensis septicæmia are not available so far as concerns the civilian population of Malta. Figures obtained from the services, however, show that a very close association used to exist between the occupation—if occupation it may be called—of the invalid and the incidence of the disease. This is well shown by a table prepared by Johnstone (Mediterranean Fever Commission Reports, Part II.) for the three large hospitals of the island—civil, naval, and military respectively. An equally if not more dangerous occupation was that of nursing, as is shown by returns of cases amongst the staffs of both military and civil hospitals. Of the rank and file of the army the occupations that showed the heaviest incidence were barrack cooks, officers' servants, mess waiters, grooms, and laboratory attendants, which together supplied more than one-fifth of the entire number of cases occurring in the garrison, and on tabulating the cases in the army in 1905, under what may be termed the "dangerous" occupations, we find that together they are responsible for 78 out of a grand total of 144 admissions for Melitensis septicæmia:—

Dangerous Occupations.

Hospital in-patients	23
Royal Army Medical Corps orderlies	16
Barrack cooks...	16
Officers' servants	12
Mess waiters	6
Grooms	3
Laboratory attendants (also Royal Army Medical Corps orderlies)	2
	78

MEDICAL INSPECTION OF SCHOOL CHILDREN.—At a meeting of the Gloucester education committee held on May 30th it was decided to appoint an assistant medical inspector of school children at a salary of £250 per annum, increasing to £300 by annual increments of £10.

The Ingleby Lectures

ON

THE DANGERS AND TREATMENT OF MYOMA OF THE UTERUS.

Delivered at the University of Birmingham on May 7th and 14th, 1908,

By CHRISTOPHER MARTIN, M.B., C.M.
EDIN., F.R.C.S. ENG.,
SURGEON TO THE BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.

LECTURE II.[1]

Delivered on May 14th.

GENTLEMEN,—In my first lecture I discussed the various dangers of myoma and the complications that may arise. I also pointed out the slender hope there was of a natural cure by extrusion of the growth per vaginam, by absorption after confinement, or by atrophy at the menopause. To-day I propose to direct your attention to the treatment of the disease. We may divide the various remedial measures into the medical and the surgical. Let us first consider the *medical (or non-surgical) methods of treatment.*

I.—NON-SURGICAL TREATMENT.

If a patient has only a small myoma, which is not growing, not causing pain, severe hæmorrhage, or interference with her health or comfort, we are not justified in advising her to undergo an operation. The case should be watched and the growth examined at regular intervals to see if it be really quiescent. A fibroid which is not actively growing may yet vary in size from time to time, being larger and more vascular just before the period and smaller after it. This is most noticeable in those cases where there is much menorrhagia. Hence, to ascertain if the tumour be *really growing or not it should be examined at the same* time after each period—say one week after the cessation of menstruation.

Rest.

It is important that a patient with a troublesome myoma should rest as much as possible. During the period she should stay absolutely in bed. If there be a tendency to flooding the foot of the bed should be raised from 12 to 18 inches on blocks. In the intervals between the periods she must avoid all strain and fatigue. Any physical exercise, if at all violent, may bring on sudden and alarming bleeding. Hence dancing, horse-riding, and cycling must be forbidden. One of my myoma patients lived in the country and used to cycle a good deal. She found that, whilst walking never brought on hæmorrhage, cycling frequently did so, and on one or two occasions caused such a severe flooding that she fainted on the road and had to be carried home. If the patient be married she should be warned of the dangers of pregnancy. In these cases I think it is our duty to tell the woman and her husband to take suitable measures to prevent conception. In all cases of polypus, in most submucous and in many interstitial fibroids, it will be found that sexual intercourse is apt to start hæmorrhage. In such cases coitus must be forbidden.

Supporting the Uterus.

The patient should be forbidden to wear corsets, as they tend to press the tumour down into the pelvis. At the same time, by obstructing the abdominal veins they keep up a condition of chronic venous congestion in the uterus and so favour hæmorrhage. On the other hand, the wearing of a light abdominal belt is sometimes beneficial, especially where the tumour is subserous, of large size, and is pressing on the bladder, the pelvic veins, and nerves. Here a well-fitting belt may comfort her by taking some of the weight of the tumour off these structures. It is sometimes useful to support the uterus from below by means of a pessary, especially in those cases of small myomata which cause retroflexion and retention of urine. In such cases the urine should be drawn off with a catheter, the patient placed in the genu-pectoral position, the impacted tumour pushed up out of the pelvis, and a large ring pessary adjusted.

---

[1] Lecture I. was published in THE LANCET of June 6th, 1908, p. 1603.

Drugs.

The treatment of myoma by drugs is unsatisfactory and resolves itself into the alleviation of symptoms. By far the most important of these is hæmorrhage.

Ergot is our chief remedy for the control of the bleeding and in many cases is of great value. It excites the contractions of the uterine muscle, and by pressing together the opposing surfaces of the mucosa checks excessive bleeding. To some extent it also acts by causing contraction of the small arterioles. I know of many cases where patients have taken ergot in drachm doses thrice a day for years and I have never seen it produce ergotism. Its use, however, is not free from objection. As Dr. Thomas Wilson has pointed out, when the heart muscle is degenerated ergot is contra-indicated. It contracts the arterioles all over the body and so increases the resistance to the left ventricle. The liquid preparations of ergot sometimes upset the digestion. In such cases it will be found that ergotin given in pill or tablet form agrees better with the stomach. It may be given hypodermically but there are many objections to this as a regular mode of administration. It is painful, and if not given with aseptic precautions may give rise to small abscesses at the seat of puncture. In emergencies, however, as when a patient is flooding severely and prompt action is necessary, a sterile preparation of ergot given hypodermically is of great value. But beyond controlling the hæmorrhage I doubt if ergot has any good effect on a myoma. The uterine contractions which it excites tend to convert an interstitial fibroid into either a subserous or submucous one. If the latter, whilst it is true that the growth becomes more accessible from the vagina, the tendency to flooding is increased. In any case, I think the prolonged use of ergot predisposes to degeneration and necrosis of the fibroid by interfering with its blood-supply.

Hydrastis is often prescribed with ergot in the form of tablets. It is an astringent to the uterine mucosa and so helps to check the menorrhagia and leucorrhœa due to the endometritis so often present. As far as I know it has no direct effect on a fibroid.

Cotarnine is a derivative of morphia and, in the form of styptol, has been recommended in cases of myoma. I have tried it in several cases but I cannot say I have seen much benefit result.

Calcium chloride has the property of increasing the coagulability of the blood, and in this way favours the natural arrest of hæmorrhage. It is thus undoubtedly of service in bleeding fibroids.

Bromide of potassium, iodide of potassium, and chlorate of potassium have all been advised in myomata but I doubt if any of them do real good. Lawson Tait, following Sir James Simpson's teaching, was in the habit of treating most cases of metritis, subinvolution, and small myomata with chlorate of potassium combined with ergot. He claimed that it was a sedative to the uterus and caused absorption of chronic inflammatory deposits. All the potassium salts are muscle poisons and tend to weaken the uterine contractions. But for the same reason they are also heart depressants and where the heart is failing may do positive harm. Bromide of potassium may be of service in allaying nervous irritability and in promoting sleep. I have never seen any benefit result from the administration of iodide of potassium, or indeed any of the preparations of iodine. I am sceptical, therefore, as to the virtues of the iodine and bromine waters of certain spas, such as Woodhall, Kreuznach, &c. Undoubtedly many patients return benefited from a visit to such health resorts—especially if there was not much the matter when they went. The change of air and scene, the freedom from home worries, the mental and physical rest enjoyed, and the regulation of the patient's diet, bowels, and habits of life—to these factors we must give the credit of whatever improvement takes place.

Tonics.—When a patient is anæmic, weak, and exhausted it is customary to give her tonics, especially iron. Whilst iron picks the patient up and stimulates the blood-forming organs it may prove a dangerous remedy by exciting alarming hæmorrhage from the uterus. It often does far more harm than good. The organic preparations of iron—such as the peptonate—seem to be less hurtful than the inorganic metallic salts. In cases of profound exhaustion it is safer to give strychnine, strophanthus, easily assimilated preparations of phosphorus, and above all the various preparations of hæmoglobin.

Laxatives.—A myomatous woman should keep her bowels well open, as constipation tends to increase congestion of the uterus through scybala pressing on the ovarian veins. Straining at stool may bring on hæmorrhage from the uterus. Further, fibroids frequently cause piles from pressure on the rectum and these as a rule are aggravated by constipation. Some mild laxative, such as cascara, sulphur, compound liquorice powder, or a saline aperient water, should be ordered.

Vaginal Plugging.

Plugging the uterus and vagina is of great help in controlling dangerous bleeding. It may tide a patient over a bad flooding and allow her to gain some strength before undergoing an operation. When called to a patient collapsed, blanched, and nearly pulseless from uterine hæmorrhage it is madness to attempt a big surgical operation such as hysterectomy. The best treatment is to put her on her side, pass a Sims's speculum, and draw down the cervix with vulsella. If the cervix be found dilated the uterine cavity should be firmly plugged with a long strip of iodoform gauze. The first few inches of gauze may be soaked with advantage in a solution of adrenalin. The rest of the vagina should then be firmly plugged with some antiseptic material, such as iodoform gauze or dry boric lint. A firm abdominal binder should be applied to exert counter-pressure on the uterus. The plugging should be removed from the uterus and vagina every 48 hours and fresh material reapplied. In this way the bleeding is controlled and the patient given time to rally. Should the myoma be submucous (and these are the cases in which there is most bleeding) the gauze packing slowly dilates the cervix and renders easy the subsequent removal of the growth. It is most unwise to apply styptics, such as alum or perchloride of iron, to the interior of the uterus to check bleeding. They lead to the formation of hard clots which, decomposing, cause sepsis and precipitate the onset of necrosis.

Electrolysis.

There is a mystery—a glamour—about electrolysis which allures patients who have a horror of the knife and who grasp at any alternative which promises relief. As a means of treatment it has been given a careful trial by scores of gynæcologists and has now been abandoned as futile and dangerous. Vineberg analysed Keith's and Engelmann's statistics, and found that out of 372 cases there were five deaths and only nine cures. Martin and Mackenrodt report 36 cases, of which 16 were distinctly made worse and three died—one from pulmonary embolism, one from necrosis, and one from suppurative peritonitis. In some cases temporary benefit was obtained in the arrest of hæmorrhage from the congested endometrium. But when the treatment was stopped the symptoms returned. In other instances, especially where the electrode was thrust into the growth, acute necrosis of the tumour occurred and endangered the patient's life. It seems to me just as rational to thrust a red-hot poker into the heart of a myoma and expect a cure to result.

II.—SURGICAL TREATMENT.

Bearing in mind the manifold dangers and complications that threaten the myomatous woman, the slender hope there is of a natural cure, and the inadequacy of non-surgical remedies, we are driven to look for help from surgery. I admit it is a choice of evils—no woman wishes to undergo an operation if she can be cured by milder measures. In the early days of abdominal surgery the major operations for the removal of a fibroid resulted in such a frightful mortality that they were only undertaken as a *dernier ressort*. But now, thanks to a more perfect asepsis and an improved technique, modern surgeons can show such a low death-rate that in the great majority of cases a radical operation can be conscientiously advised. Before discussing the merits and demerits of the various operations for myoma, let me briefly state the indications for and against surgical interference.

Contra-indications to operation.—I would not advise an operation: (1) where the tumour is smaller than an orange, is causing no symptoms, and is not growing; (2) where the patient is past the change of life and the myoma is quiescent and causing no trouble; or (3) where the patient is gravely ill from some other condition—such as phthisis, heart disease, or kidney disease—which will of itself prove fatal before long.

Indications for operation.—On the other hand, an operation is called for: (1) where there is severe bleeding, uncontrolled by rest and ergot; (2) where there is rapid or persistent growth of the tumour; (3) where there are signs of degeneration, necrosis, or malignant disease; (4) in many cases complicated with pregnancy; (5) in cases complicated with gross lesions of the ovaries and tubes; (6) where there are marked symptoms of pressure on the urinary organs; (7) where the tumour is very large and from its great bulk and weight becomes a burden; (8) in some single women where the tumour, from its size, leads to unfounded suspicions of pregnancy and causes the patient much unhappiness; and (9) in cases of sterility due to the presence of a myoma which can be removed without sacrificing the uterus. No hard and fast rule can be laid down. Each case must be considered on its merits and the question of operation decided only after due consideration of the condition of the tumour, its rate of growth, the gravity of the symptoms caused by it, and the state of the patient's general health. The operations for myoma may be divided into: (1) those performed per vaginam; and (2) those that involve abdominal section. Let us first consider the vaginal operations.

Vaginal Operations for Myoma.

Curetting.—Curetting should be performed, after the removal of a fibroid polypus or a submucous myoma, in order to cure the endometritis which generally accompanies these conditions. In some interstitial tumours, if done cautiously and aseptically, it may also do good by checking the leucorrhœa and menorrhagia, and so giving a feeble patient time to regain her strength. It is seldom, however, of more than temporary benefit, and is not without risk. If the tumour be submucous, it may cause necrosis by opening the capsule of the growth and allowing germs to get access to its structure. Further, in cases complicated with pyosalpinx or ovarian abscess curetting may be positively dangerous by the manipulations causing the pus sac to burst into the peritoneum.

Removal of polypi.—A fibroid polypus should be removed as soon as discovered. It is an easy and safe operation. In most cases it is enough to seize it with vulsella and twist it off. If the growth be large and the pedicle broad and vascular it is safer to control the bleeding with a ligature. I usually crush the pedicle with strong Spencer-Wells forceps and then tie a fine silk ligature in the groove left by the forceps. Occasionally a fibroid polypus is met with of colossal size, filling the pelvis and lifting the uterus up into the abdomen. In such cases the growth must be cut away piecemeal before the pedicle can be reached. Patients with fibroid polypi are often quite blanched from long-continued hæmorrhage, but if there be no other complication they make a rapid recovery.

Vaginal myomectomy.—Vaginal myomectomy was first performed by Amussat in 1840. The technique was developed by Atlee, Emmet, and Thomas, and perfected in recent years by Péan and Doyen. It is the operation, *par excellence*, for the removal of submucous growths. These are usually, but not invariably, single. They cause very severe bleeding; and, if of large size, block the pelvis and cause retention of urine. The uterine contractions tend to force the growth downwards, to dilate the cervix, and to convert the tumour into a fibroid polypus. During this process there is a great risk of necrosis occurring. Hence every submucous tumour should be removed without delay. Where the cervix is dilated it is usually easy to enucleate these growths, after the mucous membrane and thin remains of the capsule have been divided. If the cervix be insufficiently dilated it may be split with scissors vertically in the middle line. The growth then becomes accessible and may be removed either whole or piecemeal (*morcellement*). The cervical wound may then be closed with catgut and the uterus preserved entire. It is an ideal method in sterile women anxious to have children, and it is the one always indicated in cases of necrosing submucous fibroids. It is, however, sometimes a long and difficult operation and the patient may lose much blood before it is finished. It is usually unwise to attempt it if the tumour be larger than the fœtal head at term. During the years 1892 to 1908 I find that at the Birmingham Hospital for Women the operation of vaginal myomectomy was performed in 34 cases, with two deaths—a mortality of 6 per cent.

Ligature of the uterine arteries.—This operation was introduced by Dr. Franklin Martin of Chicago, but it has not found much favour in this country. The object is to cut off most of the blood-supply of the uterus, to check the menorrhagia, and cause the tumour to atrophy. But there is such a free anastomosis between the uterine and ovarian arteries that the latter rapidly enlarge, and soon the womb is as well supplied with blood as before. Moreover, a sudden and very marked decrease of the blood-supply may cause necrosis of the growth. It is quite an easy operation. An incision is made in each lateral fornix, the enlarged uterine arteries are felt for, exposed, and tied with stout silk—taking care, of course, to avoid including the ureter. I have performed it in two cases, but without any benefit to the patients.

Vaginal hysterectomy.—The operation of vaginal hysterectomy was first introduced for the treatment of cancer, and is said to have been performed in 1560 by Cruce of Granada, in Spain. Scattered through the surgical literature of the seventeenth, eighteenth, and early nineteenth centuries we find reports of cases by various German, French, and Italian surgeons. Hunter in 1799 was the first to do it in Great Britain, Warren in 1829 in America. The modern operation for cancer we owe largely to the German surgeons—Czerny, Schroeder, Olshausen, Fritsch, and Martin—who, from 1875 onwards, gradually developed the method. On the other hand, for the extension of vaginal hysterectomy to the treatment of myoma we are indebted to the French surgeons, chiefly to Péan in 1883, followed by Doyen and others. It is the best operation to perform in cases of small myomata—other than those which can be enucleated without sacrificing the uterus. It removes the whole of the disease; it does not involve an abdominal scar, and it is attended with but moderate risk to life. In my own practice, hospital and private, I have, up to date, performed the operation for myoma 73 times, with three deaths, a mortality of 4 per cent. It may be a dangerous operation when the uterus, with its myoma, is larger than a three months' pregnancy, if it be fixed by adhesions, if the case be complicated by pyosalpinx or ovarian abscess, or if the vagina be very narrow and rigid. In such cases it is safer to open the abdomen and remove the uterus from above. Some years ago I lost a case by not following these rules. The woman was exhausted by long-continued hæmorrhages from a big submucous myoma. I split open the uterus, enucleated the growth piecemeal, and then removed the rest of the uterus by vaginal hysterectomy. The operation, which took about two hours, was a long, difficult, and bloody one, and the patient never rallied from the shock. Had I opened from above and performed abdominal hysterectomy I feel sure I should have saved her.

Abdominal Operations for Myoma.

We now pass to the consideration of the more important abdominal operations for myoma. These fall under three headings: (1) removal of the uterine appendages (where the ovaries and tubes are removed, but the uterus with the tumour is left behind); (2) hysterectomy (where the tumour, together with most or all of the uterus, is removed); and (3) myomectomy (where the tumour is removed, but the entire uterus is saved).

Removal of the uterine appendages.—This operation was first performed by Lawson Tait in this city in 1872 and to the day of his death he was its leading exponent. It was, *par excellence*, "Tait's operation"; and for nearly a quarter of a century it held the field against all rivals. It was a fairly safe operation when the tumour was a small one, but a risky and unsatisfactory one when it was large. I find that during the years 1882 to 1908 it was performed at the Birmingham Hospital for Women 300 times with 15 deaths—a mortality of 5 per cent. In my own practice I have removed the appendages for small myomata 20 times with one death (a mortality of 5 per cent.), and for large myomata eight times with two deaths (a mortality of 25 per cent.). I have not performed the operation myself since 1896. In about 90 per cent. of the cases that recovered menstruation ceased and the tumour shrank, though I doubt if it ever completely disappeared. But in the remaining 10 per cent. the patient was not cured; the floodings continued, the tumour grew, pressed on the bladder, rectum, and pelvic nerves, and rendered the patient's life a burden to her. Moreover, it was found that even when the operation removed the symptoms due to the myoma it often led to others of a nervous character equally distressing. Such were intense heats and flushes, palpitation, headaches, nervous depression, and pelvic neuralgia. Some of these patients became neurasthenic wrecks. These sequelæ were no doubt due to the sudden cessation of the internal secretion of the ovaries—something which they manufacture, and add to the blood circulating through them, and which is essential to the well-being of the nervous system. It was these failures and bad after-effects that shook the faith of surgeons in the operation and led them to search for some more excellent way. When it was found that by improved methods we could reduce the mortality of hysterectomy and myomectomy to under 5 per cent. the operation of removal of the appendages was abandoned. None the less should we honour Lawson Tait for his genius in devising this operation and his courage in advocating it. It was at the time a great advance in gynæcology and it saved thousands of lives that would otherwise have been sacrificed.

History of abdominal hysterectomy.—The history of abdominal hysterectomy is interesting and shows by what slow and painful steps the modern operation has been evolved. The successes of to-day have been attained only after years of failure and disaster. Lizars in 1825 and Nathan Smith about 1830 opened the abdomen for supposed ovarian tumours, but finding myomata instead closed the wound without attempting their removal. Clay of Manchester performed the first hysterectomy for myoma in 1843, but his case died. He was followed by Heath in 1843 and Bellinger in 1846, also with fatal results. Burnham in 1853 did the first successful hysterectomy in America. The first successful hysterectomy in Europe was performed in 1861 by Koeberle of Strassburg who invented for the purpose the serre-nœud (or as it is commonly, but wrongly, called the "clamp"). This was an instrument by which the uterine stump was constricted by means of a wire nooze fixed in the lower angle of the wound and allowed to slough away. This extraperitoneal method—improved from time to time by Lawson Tait, Thomas Keith, and J. W. Taylor—was practised for 30 years. It was then displaced by more modern methods, with intraperitoneal treatment of the stump. We distinguish two varieties of intraperitoneal hysterectomy: (*a*) panhysterectomy, or removal of the whole uterus, including the cervix; and (*b*) supravaginal hysterectomy, where the body of the uterus is excised but the cervix is left behind.

Panhysterectomy was first performed by Bardenheuer in 1881 and he recorded seven cases with six recoveries. Mary Dixon Jones in 1888 was the first to do it in America. In this country the first to do the operation was Jessett in London in February, 1892, followed by Smyly in Dublin in the autumn of the same year. I believe I was the first to perform panhysterectomy in the provinces in 1895. In February, 1896, I read a paper before the Edinburgh Obstetrical Society describing the method of procedure and giving details of eight successful cases. Since then the method has been ably advocated by Stanmore Bishop of Manchester and Herbert Spencer of London.

The operation of supravaginal hysterectomy was really first performed in America in 1855 by Kimball, who ligatured and dropped the stump into the abdomen. It fell into abeyance till 1892 when Baer devised the modern operation where, after ligature of the ovarian and uterine vessels, the cervical stump is covered by suturing together the anterior and posterior flaps of peritoneum. This is now the favourite procedure with most gynæcologists and in the hands of such skilled surgeons as Bland-Sutton, Doran, and Haultain is followed by brilliant results,

Extraperitoneal hysterectomy.—The extraperitoneal operation was that always performed by Lawson Tait in those cases in which it was impracticable to remove the uterine appendages. The uterus, with the tumour, was delivered through the abdominal wound, transfixed with steel pins as low down as possible, and strangulated below the pins with an iron wire drawn tight by means of the serre-nœud or "clamp." In some cases a rubber tourniquet replaced the wire. The tumour beyond the pins was then cut away and the wound above it closed. The stump underwent acute necrosis and in about a week became a black, gangrenous, horribly offensive mass. This sloughed off in from 10 to 20 days, leaving a huge gaping septic chasm which took many weeks to close. It was a murderous operation, and those who recovered did so only by the skin of their teeth. They had to run the gauntlet of secondary hæmorrhage, septicæmia, peritonitis, and rupture of the septic wound with extrusion of the bowels. The death-rate was terrible—so great, indeed, that in the annual report of the Birmingham Hospital for Women for 1891 the medical staff announced that they had practically abandoned the operation.

On looking over the statistics of the hospital I find that from 1879 to 1900 extraperitoneal hysterectomy for myoma was performed 58 times with 20 deaths—a mortality of 34 per cent. In my own practice I have done the operation only eight times with two deaths—a mortality of 25 per cent. My last case was in 1895, after which I adopted the intraperitoneal method.

Intraperitoneal hysterectomy.—Under this heading we include: (1) panhysterectomy, where the whole of the uterus, including the cervix, is removed; and (2) supravaginal hysterectomy, where the cervix is left behind. Both methods have their advocates. For some years I clung to panhysterectomy as the better operation. Increased experience, however, has convinced me that in most cases supravaginal hysterectomy is preferable. It is safer for the patient and less difficult for the surgeon. The ureters and bladder are less in danger, the germ-laden vagina is not laid open to the peritoneum, and there is less interference with the integrity of the pelvic floor. The chief argument urged against supravaginal hysterectomy is that the cervix, which is left behind, may become the seat of cancer. But I do not think statistics support this objection. Therefore, contrary to what I taught in 1896, I now hold that, whenever possible, supravaginal hysterectomy should be performed in preference to panhysterectomy. The latter should be reserved for cases where the cervix is involved in the myoma or otherwise diseased. Let me briefly describe the steps of the operation, The first essential is perfect asepsis in every detail. This is far more important than speed or dexterity. The surgeon and his assistant should both wear sterilised rubber gloves over sterilised hands. Instruments, ligatures, swabs, and water are, of course, all duly sterilised. The patient should be placed in the Trendelenburg position and the operating room should have a good top light. The abdomen is freely opened and the uterus, with the tumour, is delivered through the incision. In effecting this Doyen's myoma screw is of great value, especially when the tumour is impacted in the pelvis. The ovarian vessels and the round ligaments on both sides are ligatured with silk and divided. If possible at least one ovary should be saved. The knife is run lightly across the peritoneum, in front of the tumour, above the level of the bladder, and along a corresponding line behind. If there has hitherto been any difficulty in fully delivering the growth it now comes easily up into the wound. The uterine arteries can now be felt pulsating on each side of the cervix. They must be carefully ligatured close to the uterus to avoid the ureters. The cervix is now cut across about the level of the internal os and slightly hollowed out to leave a cup-shaped surface. The muscular tissue of this concave stump is drawn together with a single row of interrupted sutures of fine silk. These suffice to control the capillary oozing. The anterior and posterior flaps of peritoneum are now sutured over the stump. Similarly, the anterior and posterior layers of the broad ligaments are brought together. The result is that, at the close of the operation, there is only a neat transverse seam running across the pelvis. The abdominal incision is closed and the patient put back to bed. It is an easy operation if the patient be thin and the tumour be confined to the body of the uterus. It may be a very difficult one in a fat woman or where the myoma has invaded the broad ligament or developed in the cervix. Whenever possible, one or both ovaries should be left behind, so as to preserve for the patient their "internal secretion." If one or both can be saved removal of the uterus causes practically no climacteric disturbances, whilst if both be removed the patient suffers severely. Of course, if both ovaries be diseased they must be taken away. The after-results of intraperitoneal hysterectomy are excellent. The patient usually makes an uninterrupted recovery and gets up with a soundly healed wound at the end of a fortnight. The mortality of the operation is small. In my own practice, private as well as hospital, I have done 51 panhysterectomies for myoma, with two deaths—a mortality of 4 per cent. I have performed 142 supravaginal hysterectomies, with three deaths—a mortality of 2 per cent.

Abdominal myomectomy.—By this we mean the removal of one or more myomata from the uterus by abdominal section, without removal of any part of the uterus. It was first performed by Atlee as long ago as 1844 but I believe this was only the removal of a pedunculated subserous fibroid. The modern operation (in which the tumours are enucleated from the substance of the womb, followed by suture of the uterine incisions and conservation of the whole organ) we owe chiefly to Martin of Berlin, Olshausen, and Kelly. It is the ideal operation for myoma and will, I believe, ultimately supersede hysterectomy for all but a small minority of cases. It removes the tumour and leaves the uterus intact. It causes no climacteric symptoms and, most important of all, it does not sterilise the patient. It may, indeed, cure sterility by removing a tumour which was preventing conception or interfering with pregnancy. It may be performed during pregnancy without necessarily interrupting the gestation or adding to the risks of the subsequent labour. In 1891 I was called in to see a case by Dr. Langsford Clay. The patient was aged 37 years and was three months pregnant. She had also two large fibroids which were causing great suffering. She had been married for many years without having been pregnant before and she was very anxious to have a child. I opened her abdomen, made incisions over the tumours, shelled them out of the uterine wall, sewed up the incisions, and closed the wound. The patient made a good recovery. She did not abort but went to term and was safely delivered of a living boy.

I have removed from the one uterus as many as eight separate myomata varying in size from that of a plum to that of the fœtal head. I always use fine silk sutures to close the uterine wounds—in one, two, or three superimposed layers. The success of the operation depends on the care with which these sutures are inserted, on the complete arrest of bleeding, and on perfect asepsis in every detail. Done carefully it is a very safe and satisfactory operation. I have now performed abdominal myomectomy 73 times with one death—a mortality of 1·3 per cent. The operation is as yet only in its infancy, but I am convinced it is the method of the future. Low as its death-rate is now, our aim must be to reduce it to zero.

Here I must draw to a close. Much has been accomplished but more remains to be done. The end of the nineteenth century witnessed a great advance in gynæcology, notably in the treatment of myoma. In the coming years I look forward to still more glorious achievements by our brethren—those workers for humanity seen in the poet's vision—

> "Ever reaping something new :
> That which they have done but earnest of the things that they shall do."

A CONTRIBUTION TO THE BACTERIOLOGY OF CEREBRO-SPINAL MENINGITIS.

By W. JAMES WILSON, B.A., M.D. R.U.I.,
D.P.H. Cantab.,
JOINT LECTURER ON SANITARY SCIENCE, QUEEN'S COLLEGE, BELFAST.
(*From the Musgrave Pathological Laboratory.*)

Part I.—A Gram-negative Diplococcus occurring in the Fæces of Cerebro-spinal Fever Patients.

At the present time, when so much attention is being paid to Gram-negative cocci, a description of an organism of this class found by me on three occasions in the stools of cerebrospinal fever cases may be of interest.

This organism, though bearing a superficial resemblance to the meningococcus, is quite distinct from it and that it had nothing to do with the meningitis from which the patients suffered was shown by the following facts: (1) typical meningococci were cultivated from their cerebrospinal fluid; and (2) the blood serum of these cases had a high opsonic index as regards the true meningococcus, but a normal index as regards this organism. The organism is of interest from the fact that its habitat is in the intestine. Tissier[1] in a recent paper refers to two obligatory anaerobic Gram-negative cocci occurring in the stools of young children. To these species the names staphylococcus parvulus and diplococcus orbiculus have been given. The researches of Dunham,[2] Goodwin and Sholly,[3] Gordon,[4] Arkwright,[5] and others have demonstrated the constant occurrence of aerobic Gram-negative cocci in the nasopharynx, but I can find no reference to their presence in fæces.

Further research may show the presence in the intestine not only of Gram-negative cocci simulating meningococci but also of the meningococcus itself, since the progress of research more and more indicates the intestine as the route by which pathogenic organisms enter the system.

Characters of this Organism.

Morphology.—It is a diplococcus having the coffee-bean appearance of the meningococcus but is somewhat smaller. In broth cultures it appears as ovate diplococci but short chains consisting of four to six individuals are also seen. It entirely fails to retain the dye in staining by Gram's method.

Cultural characters.—On agar stroke cultures appear as a thin film of growth, greyish by reflected, bluish by transmitted, light. Agar plates: surface colonies at the end of 48 hours at 37° C. have a diameter of 5–7 millimetres. They are circular, have an even edge, and are somewhat like meningococcal colonies, but are less raised. The flatness of the colonies renders them more transparent than those of the meningococcus and very much less opaque than those of the micrococcus catarrhalis. The colonies have a curious ringed appearance which may be compared to that presented by a transverse section of a young tree. The deep colonies are of a brownish yellow colour and shaped like a whetstone. The growth on gelatin at 20° C. is good and is very similar to that on agar. No liquefaction of the medium occurs. Bouillon becomes uniformly turbid. No formation of a pellicle on the suface. In litmus milk no acid formation and no coagulation, but bleaching of the litmus occurs. In bouillon containing 1 per cent. of glucose, lævulose, galactose, lactose, maltose, saccharose, mannite, and salicin respectively no acid or gas formation occurs, but instead increase of alkalinity.

The vitality of the organism is good as a subculture can readily be obtained from a culture two months old.

Pathogenicity.—A guinea-pig was inoculated intraperitoneally with the contents of three agar cultures without presenting any ill-effects.

Like that of the meningococcus the growth of this organism on an agar or ascitic agar tube forms a good emulsion with normal saline solution and there is no tendency to clump formation, in these respects differing markedly from the micrococcus catarrhalis. In its absence of acid production in sugar-containing media this organism resembles the micrococcus catarrhalis, but morphologically it is smaller than the latter and culturally the surface colonies are not so opaque. From the meningococcus it is distinguished by its greater vitality, its growth at 20° C., and by the fact that the meningococcus forms acid in media containing glucose. These same characteristics distinguish it from the gonococcus.

The organism is of interest as being an intestinal saprophyte from which a pathogenic parasite might possibly be evolved. That organisms of the same class may be pathogenic is shown by the fact that a coccus somewhat resembling this one was obtained by W. E. Marshall from a case of cerebro-spinal meningitis. J. A. Arkwright[6] gives the following description of Marshall's organism: "On subculture, however, it grew well on agar but always discretely, and the colonies were whiter than those of the meningococcus. It grew in broth, rendering the medium uniformly turbid, and the colonies on agar were not coarsely granular, and were moist and rather sticky. An emulsion was easily made and did not agglutinate spontaneously. In these respects it resembled the meningococcus very closely, but it grew on gelatin at 22° C. without liquefaction; it failed to produce acid from glucose, maltose, or galactose, and an emulsion was not agglutinated by meningococcic serum in dilutions of 1 in 2 and 1 in 10. Moreover, in a film from the original colony the cocci were rather larger and stained better with methylene blue than it is usual for meningococci to do. It is therefore clear that this organism is not the meningococcus. It resembles micrococcus cinereus of v. Lingelsheim in most particulars."

In Part II. a description is given of a case of cerebrospinal meningitis, in which the infecting micro-organism was very similar to, but not identical with, the one just described.

Part II.—Cerebro-spinal Meningitis due to Infection with an Organism of the Micrococcus Catarrhalis Class.

At the present time cerebro-spinal meningitis and influenza are present in epidemic form in Belfast. It has been shown in a previous communication by Professor W. St. C.

[6] Arkwright, ibid., April, 1907, p. 199.

Symmers and myself[7] that the majority of the cases of meningitis are due to infection with the micrococcus intracellularis meningitidis (Weichselbaum). In certain cases, however, we have found that the symptoms were due to infection with such different organisms as the pneumococcus (one case), streptococci (seven cases), the bacillus typhosus (one case), the bacillus enteritidis of Gaertner (one case), and the bacillus anthracis (one case).

The present case is of interest in that the infecting organism was one of the micrococcus catarrhalis class. The clinical history (for an account of which I am indebted to the kindness of Dr. Herbert H. Prentiss, resident medical officer at the Belfast Fever Hospital, Purdysburn) is similar to that of a fulminant attack of cerebro-spinal fever.

The patient, an infant, aged three months, was admitted to hospital at 12.30 A.M. on Feb. 21st, 1908, with a history of an illness of 21 hours' duration. The child was first noticed to have difficulty in breathing; then to become peevish and to cry incessantly. On admission the temperature was 97° F. and the pulse was rapid. The skin was normal except for a few petechial spots on the buttocks. The eyes, the ears, and the throat were normal. There was no rigidity of the neck or of the spine. A slight indication of Kernig's sign was present. The heart and lungs were normal. The lymphatic glands in the posterior triangle of the neck and in the right axilla were enlarged and shotty. The tongue was slightly furred. On Feb. 21st the temperature throughout the day showed a steady rise, being 98·4° F. at 9 A.M., 101° at 5 P.M., 102° at 9 P.M., and 103° at 1 A.M. The child never ceased crying and never slept. There were a petechial rash and mottling over the buttocks, the lower limbs, and the back. The fontanelles were bulging. Lumbar puncture was performed at 3 P.M. and six drachms of turbid fluid were obtained and 30 cubic centimetres of Flexner and Jobling's serum were injected. At 7.20 P.M. convulsions were present, almost all the muscles of the body twitching. The eyes twitched from side to side and up and down. There were frothing at the mouth and vomiting. All the surface of the body except the palms of the hands and the soles of the feet was covered by dark bluish-red patches and blotches which faded on pressure. The pulse was very rapid and weak. Respiration was rapid. Death took place at 2 A.M. Thus the total duration of the illness was about 47 hours.

The lumbar puncture fluid was turbid and there was a large deposit of pus cells. A film made from the deposit and coloured with Leishman's stain showed large numbers of leucocytes and diplococci. Many of these cocci were extracellular and many intracellular, the extracellular staining well, the intracellular faintly. Most of the cells contained granules; some of these cells had the typical appearance of polymorphonuclear leucocytes, in others the nucleus was round and undivided; both varieties, however, were markedly phagocytic. A differential count of 200 cells gave the following result. Granular cells, polymorphonuclear 35 per cent. and mononuclear 59 per cent.; transitional cells, 3 per cent.; large lymphocytes, 1·5 per cent.; and small lymphocytes, 1·5 per cent.

Characters of Organism.

Morphology.—Diplococci having the coffee-bean shape and size of the meningococcus. Short chains of four individuals occur and here and there threads of considerable length which only at their ends show evidence of segmentation into cocci. The cocci, which are quite Gram-negative, stain more uniformly than meningococci, there being few degenerate forms.

Cultural characters.—On agar the organism grows well, the growth being greyish by reflected and somewhat bluish by transmitted light. The growth is more opaque than that of the meningococcus. Subcultures as well as the original culture made from the cerebro-spinal fluid grew well on agar, in this respect differing from the meningococcus which requires the addition of ascitic fluid or serum to enable it to grow when recently isolated. On gelatin at 20° C. good growth occurs without liquefaction. In stab cultures there is a greyish streak of growth along the stab and on the surface a very opaque white colony. On the Drigalski-Conradi medium good growth occurs. This is an important distinction from the meningococcus, the latter showing no growth on this medium. Bouillon and peptone water become uniformly turbid. No indol is formed. In faintly alkaline litmus bouillon containing 1 per cent. of the following substances, glucose, lævulose, galactose, lactose, saccharose, maltose, dextrin, inulin, glycerine, erythrite, adonit, mannite, dulcit, arabinose, raffinose, salicin, sorbit, and amygdalin, no acid was produced but rather increase of alkalinity. The tubes contained a uniform turbid growth with thin iridescent pellicle on the surface. In many cases bleaching of the medium occurred but the blue colour returned when the tubes were left all night at room temperature. In litmus milk the bleaching of the litmus caused the milk to acquire a pinkish shade. Shaking with air brought back the blue colour. No clot formed. Under the anaerobic conditions obtained by Buchner's tubes good growth occurred and no change in colour was produced in neutral red broth. The vitality of the organism was good, as subcultures could readily be obtained after three weeks at room temperature.

Pathogenicity.—A mouse inoculated intraperitoneally with the contents of one half of an agar slope culture collapsed at once and died in 15 minutes. Another mouse inoculated subcutaneously with the rest of the agar culture died in six hours. There is probably, therefore, present in cultures of this organism substances toxic to mice. A guinea-pig inoculated intraperitoneally with the contents of half an agar tube suffered no ill effects.

The opaque and somewhat granular nature of the colonies on agar and the readiness with which the organism grows on this medium, the occurrence of growth at 20° C., and the absence of any acid production in glucose media, distinguish this Gram-negative coccus from the meningococcus and gonococcus. It conforms in most particulars to descriptions of the micrococcus catarrhalis but differs from it in that it shows a tendency to grow in short chains. This organism forms a uniform emulsion in salt solution and does not clump so readily as the micrococcus catarrhalis.

The early death of the patient prevented me from testing the opsonic index of his blood serum with respect to the meningococcus and this organism. The blood serum, however, of a well-marked case of cerebro-spinal fever which was rich in agglutinins and opsonins for the meningococcus gave a normal opsonic index with respect to this coccus.

A brief *résumé* of the history of the micrococcus catarrhalis may be of interest. This micro-organism was originally found by Seifert[8] in sections of lungs of people who had died from influenza. Kirchner (1890) cultivated it from cases in which the clinical diagnosis was influenza. R. Pfeiffer cultivated it from cases of febrile bronchitis and gave it the name micrococcus catarrhalis. Later (1902) Ghon and H. Pfeiffer found it in a large series of cases of epidemic bronchitis. Bezançon and de Jong[9] (1905) and Dunn and Gordon[10] (1905) found the micrococcus catarrhalis in epidemics simulating influenza. It is of interest to note that in the epidemic described by Dunn and Gordon cerebro-spinal symptoms were present in many of the cases and in one case Gram-negative diplococci were found in the meningeal pus, but a culture could not be obtained. In the same year (1905) Davis[11] closely studied the micrococcus catarrhalis. More recently (1907) Arkwright[12] described an organism which had been isolated from the lumbar puncture fluid of a case of cerebro-spinal meningitis and which differed from the micrococcus catarrhalis (1) in that it formed moist and sticky colonies on agar and (2) in that an emulsion was easily made and did not agglutinate spontaneously. Arkwright states that his organism resembles the micrococcus cinereus of von Lingelsheim in most particulars. The organism described in this paper seems to me to be identical culturally with that described by Arkwright; to test absolute identity would require a determination of the opsonic and agglutinative properties of each. Barker (1908)[13] mentions the discovery of the micrococcus catarrhalis in the lumbar puncture fluid in a case of otitic meningitis.

The Gram-negative fæcal diplococcus differs from the present one in being smaller morphologically and in having a flatter and more delicate growth on agar.

In conclusion, my best thanks are due to Dr. A. Gardner Robb, Dr. Prentiss, and to Professor Symmers for giving me every opportunity and facility to investigate this case.

Belfast.

THE TREATMENT OF INTRACTABLE HAY FEVER AND PAROXYSMAL CORYZA BY RESECTION OF THE NASAL NERVE.

By EUGENE S. YONGE, M.D. EDIN.,
HONORARY ASSISTANT PHYSICIAN TO THE MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT.

FOR those cases of hay fever which may be termed "desperate," where all treatment has proved unavailing, where the patient is condemned to an annual period of miserable discomfort and of complete incapacitation, where, it may be, Ossa is heaped on Pelion by the supervention of chronic asthma or other sequelæ, almost any new plan of treatment that is legitimate is, I think, worthy of trial, provided that there are reasonable grounds for supposing the treatment to be capable of giving relief and assuming that the usual recognised therapeutic measures have been fairly weighed in the balances and found wanting. I propose, in the present communication, to describe a new method of treatment which appears to be applicable for these severe and intractable cases and which, up to the present, has given most satisfactory and encouraging results.

The method is based on the theory that the stimulus which induces the reflex manifestations that are observed in hay fever and in paroxysmal coryza[1] is conveyed to the centres by the nasal nerve (nasal branch of the fifth), this nerve therefore being the afferent path of the reflex. If this theory be correct the prevention of the attacks, which characterise hay fever and its congeners, by resecting a portion of the nerve on each side would apparently be possible. The evidence which can be adduced in favour of the theory may therefore be briefly examined. In this connexion there is to be considered, in the first place, the evidence suggested by a consideration of the distribution and the functions of the nasal nerve; in the second place, that suggested by the effects of a particular form of treatment (cauterisation of the nasal mucous membrane); and in the third place that suggested by the effects of bilateral resection of the nerve.

The distribution and functions of the nerve.—Many of the so-called "reflex nasal neuroses" represent an exaggeration or a tendency to precipitation of the normal nasal reflexes. In this category may, for instance, be included the neurosis known as *paroxysmal sneezing*, also that which is designated *paroxysmal rhinorrhœa* where the predominant symptom is reflex hypersecretion from the nasal mucous membrane. It seems not unreasonable to suppose that morbid or exaggerated reflexes of this character usually, although, of course, not invariably, follow the same afferent and efferent paths as the normal reflexes which they represent. Of the *afferent* paths, with which we are at present mainly concerned, for the normal reflexes of sneezing, of vaso-motor turgescence, and of nasal secretion only that for sneezing has, so far as I am aware, been exactly determined. The observations of Wertheimer and Surmont[2] appear to show that the stimulus for the ordinary sneezing reflex is conveyed by the nasal nerve and it may be conjectured that the stimulus which induces the manifestations of *paroxysmal sneezing* travels up the same nerve. The sneezing which sometimes occurs when a beam of bright light falls on the eye is generally considered to be also referable to this nerve, the impulse travelling from the eye *viâ* the ciliary branches. The afferent impulse for the other reflexes, vaso-motor and secretory, which have been mentioned, is usually stated, in rhinological works, to be conveyed by the "nerves of ordinary sensation," without reference to any special nerve being concerned. The nasal branch of the fifth is, of course, not the only sensory nerve of the nasal cavity as there are filaments, principally derived from the spheno-palatine ganglion, distributed to the posterior parts of the cavity. I believe, however, on theoretical grounds, that the nasal nerve conveys the impulse not only for the sneezing reflex but also for the other normal reflexes referred to. Moreover, I think it is this nerve which is also responsible for the conveection of the abnormal reflexes which are represented in the condition known as paroxysmal coryza and in hay fever, this conclusion being based on a surer foundation than the foregoing—namely, on the effects observed after division of the nerve.

In the clinical manifestations of hay fever we have, I think, a strong suggestion of the part played by the nasal nerve in relation to this malady; for if the clinical manifestations be considered in relation to the distribution of the nerve, it will be found that they closely correspond in localisation to the areas to which the latter is distributed, and, moreover, that the symptoms would be explicable on the assumption that they represent the reflex effects of irritation of the nerve. It will be recollected that the nasal nerve not only supplies the anterior region of the nasal cavity, but also sends branches to the conjunctiva, the lacrymal sac, the iris, ciliary muscle and cornea, the frontal sinus, the skin of the alæ and the tip of the nose, and the skin of the upper and lower eyelids. Let us take now the characteristic symptoms of hay fever. The initial symptom is usually a sensation of itching at the inner canthus. Following upon this is a feeling of irritation in the nose succeeded by sneezing, nasal obstruction, and hypersecretion. The patient may complain of frontal headache or of a sensation of constriction above the eyes. The eye-symptoms consist generally of congestion of the conjunctiva, lacrymation, and redness and swelling of the lids, and a certain degree of photophobia often supervenes. Usually also there is some redness of the skin at the tip and sides of the nose. The following table gives the symptoms of hay fever, together with the distribution of the nasal nerve:—

Branches of the nasal nerve.	Distribution of the branches.	Symptoms characteristic of hay fever (assumed to represent the reflex effects of irritation of the branches of the nasal nerve).
Internal branch.	Anterior part of septum.	Sneezing. Hypersecretion. Nasal obstruction. Relieved or cured by application of galvano-cautery to anterior parts of nasal cavity.
External branch.	Anterior part of external wall of nasal cavity.	
Infratrochlear branch.	Caruncula lacrymalis. Conjunctiva. Lacrymal sac. Integument of eyelids.	Itching at inner canthus. Congestion of conjunctiva. Lacrymation. Redness and swelling of eyelids.
Branch to frontal sinus.	Mucous membrane of frontal sinus.	Frontal headache.
Anterior branch.	Alæ and tip of nose.	Redness of alæ and tip of nose.
Long ciliary nerves. Branch to ciliary ganglion.	Ciliary muscle, iris, and cornea.	Photophobia.

The effects of cauterising the nasal mucous membrane.—The fact that in many instances benefit may be obtained as regards the hay fever attacks and the paroxysms of vaso-motor rhinitis by the application of cocaine during the attacks, or of the galvano-cautery between the attacks, to special areas in the anterior region of the nose, has been recognised for a considerable time, but the manner in which the beneficial effects are brought about not being evident, the treatment has commonly been regarded as empirical. Nevertheless, the fact that this relief is afforded by cauterising the nasal mucous membrane in the region supplied by the nasal nerve appears to me to be corroborative of the suggestion that the terminal filaments of this nerve represent the starting-point of the reflex disturbances and that the partial or total failure of the latter to be induced, in those cases in which the mucous membrane has been cauterised, is referable to the irritability of the terminal filaments having been diminished or abolished.

The effect of bilateral resection of the nasal nerve.—The strongest evidence in favour of the theory, if *ex post facto* proof may here be considered, is supplied by the effects which have been observed to follow bilateral resection of the nerve. In various forms of vaso-motor rhinitis in which this operation has been performed by me, the symptoms have been completely and, up to the present, lastingly abolished. It may be mentioned that in the first case in which the operation was performed the nerve, to begin with, was divided on the right side only. As a result of this procedure the symptoms—intermittent nasal obstruction with profuse hypersecretion—were abolished in the nasal cavity corresponding to that on which the nerve had been divided, whereas the disturbances continued to recur periodically in the opposite nasal cavity, as before the operation. The sensation experienced when these attacks occurred was described by the patient as a "feeling of the nose being divided in half," one side being clear and the other obstructed. The asthmatic attacks from which the patient suffered also continued to recur at intervals. After section of the nerve on the left side the nasal symptoms entirely disappeared and the attacks of asthma ceased.

---

[1] Paroxysmal coryza (variously termed "vasomotor coryza," "vasomotor rhinitis," "paroxysmal sneezing," &c.), is a pathological process which is essentially identical with hay fever, differing only in the nature of the exciting cause and the degree of severity.

[2] Wertheimer and Surmont: Les Voies Centripètes du Réflexe de l'Éternûment, Comptes Rendus de la Société de Biologie, 1888, p. 62.

The considerations which, in the first instance, suggested that resection of the nerve might be performed with a successful result in severe cases of hay fever and paroxysmal coryza in which other methods had failed, were of course those relating to the functions and distribution of the nerve, &c., which I have already detailed. The following notes of the first case, which was operated upon, will serve to indicate the nature of the procedure and the description of case for which I have felt justified in recommending it:—

The patient, a male, aged 45 years, was first seen in 1907. He complained of asthma and intermittent attacks of nasal obstruction, sneezing and nasal discharge; also, in the summer, of severe attacks of hay fever. He had suffered from hay fever for about 15 years and had had asthma for about the same length of time. The hay fever generally began about the last week in May and continued for about six weeks. During this period he suffered great distress and was quite incapacitated for business. He frequently "wished he was dead." The asthma had gradually become more and more troublesome and he now experienced a bad attack every few weeks with frequent minor attacks in the intervals. In consequence of these he rarely enjoyed a proper night's rest and was often prevented from attending to his occupation. The patient had had treatment from a rhinologist for the hay fever and asthma by galvano-cautery, &c., without benefit to either condition; other methods of treatment had also been tried but no measures whatever had apparently been of any real value. There was a history of rheumatic fever in youth and of expectoration of blood. At the time of examination there was some emphysema, together with cardiac dilatation.

Operation.—Resection of the nasal nerve on the right side was first performed, chloroform anæsthesia being employed. The nerve was reached by an incision at the inner edge of the orbit, commencing just above the inner canthus and extending upwards and slightly outwards for about two-thirds of an inch. The cellular tissue having been cleared from the inner upper wall of the orbit by means of a blunt dissector and the nerve located at the anterior ethmoidal foramen, the latter was separated from the artery and divided close to the foramen, about a quarter of an inch of the nerve being removed. Horse-hair sutures were inserted and the wound was dressed with gauze and collodion. The stitches were removed on the fourth day. Resection of the nerve on the left side was carried out four weeks later.[3]

As I had been unable definitely to promise the patient a cure, or indeed any improvement, on account of the dearth of previous observations relating to the effects of resecting the nerve, I was much pleased when, two months after the operation, he called on me with the information that there had been an entire absence of the attacks of paroxysmal coryza and sneezing and a complete cessation of the asthma. He stated also that he had experienced much comfort and benefit from the increased freedom of nasal respiration[4] and owing to the fact that he was able to insure a good night's rest. He had gained over half a stone in weight since the operation and his appearance indicated a manifest improvement in his general health. The minute scars on the skin were barely discernible even on close inspection. On examining the anterior part of the septum with a probe it appeared somewhat less sensitive than normal, but there was no definite anæsthesia either of this region or of the conjunctiva or the skin.

The effects of the operation in this case were such as to encourage me to perform it in other patients suffering from severe conditions of a similar character. Up to the present the results, as already mentioned, have been of a most encouraging nature, not only with regard to hay fever and paxoxysmal coryza but also with regard to the remaining constituent of the triad, which so often afflicts hay fever patients—viz., asthma. The fact that asthma is frequently associated with the foregoing neuroses and is often relieved by similar therapeutic measures suggests that, at least in some instances, there exists a pathogenetic relationship between the conditions, and the existence of this relationship doubtless explains the relief which has been afforded in my cases.

In conclusion, I desire to point out that the present paper merely constitutes a preliminary communication on the subject, as it would be premature, at any rate as yet, to form any final conclusions as to the permanence of the results obtained by this method of treatment or as to the entire absence of unfavourable effects.[5] Nevertheless, in view of the intractable nature of the maladies for which the operation is suggested I have thought it worth while to publish my observations in their present form for the consideration of those who may be interested in the subject.

Manchester.

THE GASTROSCOPE.

BY ALBERT E. MORISON, M.B., C.M. EDIN.,
F.R.C.S. EDIN.,
SURGEON TO THE HARTLEPOOLS HOSPITAL.

GASTRO-DUODENOSCOPY AND DIAPHANOSCOPY.

THROUGH the kindness of Professor Thorkild Rovsing of Copenhagen, who was recently on a visit here, I was enabled to see his gastroscope for electric illumination of the stomach by transillumination and gastroscopy, of which he demonstrated the use on a patient in the Royal Victoria Infirmary, Newcastle-on-Tyne.

All surgeons must have realised the difficulty in making an exact diagnosis of diseases of the stomach, and these may not be cleared up when the stomach is exposed by operation for thorough examination by ordinary inspection and palpation. Doubt frequently exists as to the pathological conditions that are present—e.g., cases occur where the differential diagnosis between carcinoma and simple inflammatory exudation around an ulcer is not easy—or hæmorrhage from a small mucous erosion may be very difficult to trace to its source; or in cases of multiple ulcers one or more may be overlooked. In such cases Rovsing's gastroscope will be of immense service to supplement other known means of diagnosis.

Rovsing made his first observation on Nov. 7th, 1907. The patient, a woman, aged 50 years, had been ill for three years and was on admission frequently vomiting and in a very wretched and emaciated condition. No tumour could be felt, there was no retention 12 hours after a Bourget test meal, and after a Ewald test meal there was brought up 170 cubic centimetres of lumpy, somewhat slimy stomach contents with free hydrochloric acid 31 and a total acidity of 58. By Roentgen illumination after a pint of bismuth porridge the stomach was found to be much depressed, the small curvature being five centimetres and the greater 11 centimetres below the umbilicus. At the operation the diaphragm was found to be depressed, the edge of the liver reached to the umbilicus, and the stomach was as described. The stomach and six centimetres of duodenum were easily drawn outside of the abdomen; the pylorus admitted the forefinger, and no definite infiltration or thickening of the stomach wall was to be felt. Only on the boundary between the cardiac end of the stomach and the small curvature could a suspicious thickening be palpated. It was impossible to say whether this were only due to a normal fold the stomach wall forms here or to an ulcer. Through a small incision one centimetre long made in the anterior wall of the stomach Rovsing inserted a ureter-cystoscope, to the catheter canal of which he fitted a ball bellows, and making the opening in the stomach air-tight by passing a purse-string suture round the cystoscope he inflated the stomach with air until all the folds of the mucous membrane were smoothed out. As soon as the cystoscope lamp was lighted the whole of the stomach was illuminated like a faintly rose-coloured cupola. All the details in the walls of the stomach could be seen, the muscular fibres, the fine network of veins, &c. A slight bleeding point close to the incision appeared as a dark red spot from which a small stream of blood was seen to be oozing down the inner wall. No shadows or thinned portions were seen. The mucous membrane was then systematically examined through the cystoscope from the cardiac orifice to the pylorus but no abnormality was found. The cystoscope was next passed through the pylorus into the duodenum, and the posterior wall of the stomach was illuminated by lifting up the omentum and transverse colon. The gastroscopy opening was closed and gastropexy was performed. All the patient's symptoms disappeared. She can now eat any kind of food, has increased in weight by 22 pounds, and is capable of doing her ordinary work.

---

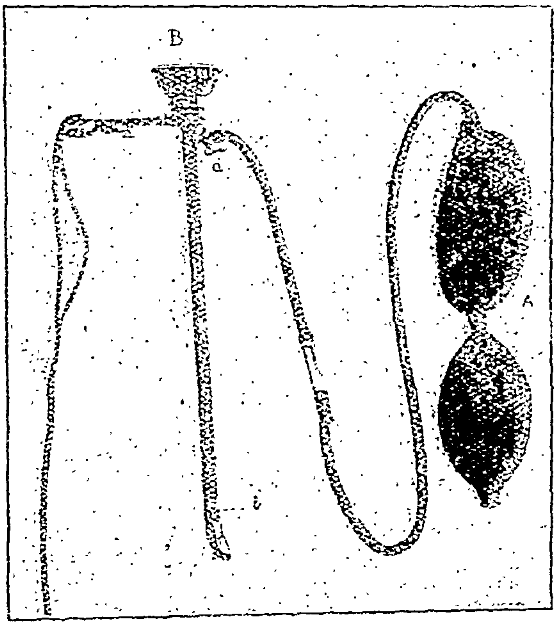
[3] In all subsequent cases I have resected the nerve on both sides at the same operation.

[4] Permanent increased freedom of nasal respiration (apart from the immunity from periodical or seasonal attacks of nasal obstruction) has been noted in several of the cases in which this operation has been done.

[5] In a recent case, in which there was some myopia, this appeared to be slightly increased after the operation.

This case demonstrated clearly that in direct diaphanoscopy and gastro-duodenoscopy a new method of examination had been found which would prove of great value in doubtful cases of stomach and duodenal disease. With the cystoscope which Rovsing first used for this purpose systematic examination of the whole mucosa of the stomach occupied too long a time not only in the interests of the patient but also because it was very fatiguing to the surgeon. He accordingly had made an instrument very much larger than the cystoscope which he calls the gastroscope, and this increases both the strength of the illuminating power and the area of vision which it is possible to see at once. The gastroscope in shape and construction resembles an enlarged Nitze cystoscope, the tube being about four centimetres in circumference, is fitted with a flattened tube along its anterior surface (*a* to *b*, Fig. 1), with a stopcock at *a* connected with a bellows (A). With this instrument even an unskilled observer is able to examine the whole of the gastric mucous membrane systematically in a few minutes. The method of use is as follows: (1) diaphanoscopy, and (2) gastroscopy proper—i.e., the inspection of the mucous membrane of the stomach and duodenum.

FIG. 1.



Gastroscope for diaphanoscopy and gastroscopy. A. Bellows for inflating stomach. B, Gastroscope. *a*, Stopcock. *b*, Opening of inflating tube.

1. *Diaphanoscopy.*—The stomach is drawn out of the abdomen and a *small incision* fitting tightly round the instrument is made into it through which the gastroscope is passed. If the stomach wall does not fit tightly round the gastroscope a purse-string suture round the incision will make it do so. The stomach is then distended with air by the bellows attached to the gastroscope. The lamp is lighted and (especially if the operating room is darkened) the stomach is seen as a brilliantly lighted cupola. All the anatomical details stand out clearly—the pinkish-coloured wall with the vessels plainly defined, the various layers of the muscular fibres, while the crypts become visible as small white spots on the pink ground. Abnormalities are readily detected—e.g., in gastritis the wall of the stomach becomes a deep pink or a bluish red colour, and the blood-vessels are seen as a close network owing to the dilatation of the smaller vessels. Tumours or growths appear as dark diffused shadows on the otherwise clear wall. The deep chronic ulcer with much surrounding inflammatory exudation and thickening shows as a central excavated or cicatrised portion of porcelain-like whiteness and with but few vessels, and this contrasts strongly with the surrounding pink wall. A small superficial ulcer of the mucous membrane is not easy to discover by diaphanoscopy, but it is easily seen by examination by gastroscopy. A bleeding ulcer, however, can be seen either covered by blood clot as a dark spot in the pink wall, or if actually bleeding a dark streak can be observed trickling towards the larger curvature. It is in cases of this description where even at a post-mortem examination the bleeding mucous ulcer is with difficulty localised that the chief use of diaphanoscopy will be found. Rovsing quotes the following as an instance. On Feb. 17th a woman, aged 38 years, was admitted into the Frederiksberg Hospital. For a month previously she had been suffering from slight dyspeptic attacks, but on the day of her admission she fainted suddenly and showed all the symptoms of profound anæmia. Shortly after she vomited a large quantity of dark blood. On examination in hospital the hæmoglobin was found to be 55 per cent., and in spite of most careful dieting the anæmia and faintings increased. There was constant melæna and on the 29th the hæmoglobin had diminished to 28 per cent. and she was very ill. She was then removed to the surgical wards under Mr. Kraft and two hours later he performed laparotomy. On opening the peritoneum the thin, flabby stomach was pulled out. Neither by inspection nor by palpation was it possible to discover any ulcer. Diaphanoscopy with Rovsing's gastroscope showed upon the otherwise clear and transparent anterior wall of the stomach a small dark spot to which a fairly large-sized artery was seen to pass and suddenly stop. Corresponding to this spot, examination of the mucosa through the gastroscope showed a very small superficial ulceration partly covered by blood clot. Examination of the rest of the mucous membrane of the stomach and of the first portion of the duodenum showed nothing abnormal. The gastroscopy incision was now carried up to where the dark spot had been observed and a superficial ulcer of the size of a pin's head was at once found and when touched began to bleed. Four pairs of catch forceps were then placed outside the ulcer to raise it from the surrounding wall, a ligature was tied round it, and bleeding was stopped. The patient's recovery was tedious but uninterrupted.

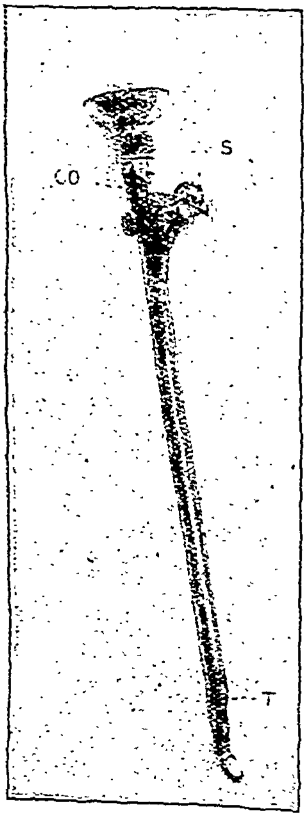
It is in most cases impossible to decide by illumination whether a tumour-like infiltration round an ulcer is inflammatory or cancerous, although a dark shadow indicates tumour and a fainter or lighter shadow inflammatory thickening. To inspect the posterior wall of the stomach efficiently by diaphanoscopy the omentum and transverse colon must be lifted up. When the stomach has been thoroughly examined the gastroscope is carried through the pylorus into the duodenum. If there is any difficulty in passing it through it is a sign that the orifice is contracted. The duodenum can be more effectually illuminated than the stomach on account of its thinner walls and smaller size and an ulcer or tumour is easily discernible.

2. *Gastroscopy.*—Simple illumination of the stomach gives a great deal of information; in many cases it allows of a definite diagnosis—gastritis, ulcer, or tumour; in most cases it is an excellent guide for the subsequent gastroscopy, because one immediately makes for the point where abnormal conditions have been shown by diaphanoscopy, and if there is any doubt as to the nature of the disease direct observation through the gastroscope will, as a rule, clear up the difficulty. The picture obtained through the gastroscope is much sharper, better defined, and more certain than that obtained by the naked eye only, for not only is it considerably enlarged and the illumination exceedingly brilliant but the inflation of the stomach causes all the folds of the mucosa to be smoothed out and more accessible to the eye of the observer. It is therefore possible to make a systematic inspection of the entire stomach and the upper portion of the duodenum in a few minutes.

The normal mucous membrane of the stomach appears by gastroscopy as a smooth rose-coloured surface which at the pyloric and cardiac orifices changes into folds of mucous membrane converging as radii towards the circular opening. Any abnormality of these two openings shows itself in a very characteristic manner: if the pylorus is ring-shaped, infiltrated, and contracted a stiff gaping ring through which a glimpse into the duodenum is obtained is observable; should half of the pyloric ring be infiltrated it assumes the shape of a half moon, the soft mucous membrane of the healthy portion curving into the stiff half of the ring. Any ulcers at the pylorus itself are easily discernible but the folds of the mucous membrane round the pylorus require a closer observation. In the one case where Rovsing had an opportunity of examining an abnormal cardiac orifice the gastroscope gave an exceedingly fine and clear picture of the tap-shaped ulcer projecting into the stomach and the adjoining portion of the mucosa ulcerated.

In cases of ulcer and carcinoma where the diagnosis is clear gastroscopy is of importance because it shows accurately the limits of the disease. It is also useful in clearing up conditions which diaphanoscopy could not—e g., in several of Rovsing's cases what after other examination was thought to be a simple ulcer, by gastroscopy showed knotty tumour formation in the mucous membrane, and no doubt was then entertained as to the malignant nature of the infiltration. But very important also is the fact that gastroscopy is able to show the presence of mucous ulcers which are not discernible by any other method.

FIG. 2.



Gastroscope for introduction of œsophageal bougie or catheter through the cardiac orifice of the stomach. S, Screw. T, Tongue. C. O., Catheter opening.

The instrument shown in Fig. 2 is oval in contour and in addition to the air-inflating tube contains a tube for the insertion of an œsophageal catheter or bougie. It is fitted like the Albarran ureter-cystoscope with a tongue which by means of a screw can be raised or lowered to direct the bougie or catheter into the cardiac orifice. By means of this instrument a retrograde insertion of a bougie can be made with the greatest ease and under ocular control for the dilatation of œsophageal strictures which are impermeable from above. Being oval, this *œsophagus* gastroscope requires a purse-string suture round it so that the edges of the stomach incision are air-tight.

Rovsing relates 26 cases in which he has been able to examine the stomach by diaphanoscopy and gastroscopy and afterwards proceed with the operation he then found to be necessary. The use of "cold" lamps in the gastroscope excludes any risk of burning the mucous membrane and a careful inflation of the stomach appears to be harmless. The risk of infection of the wound is overcome by sterilising the whole instrument—gastroscope, wires, tube, bellows—for 36 hours in a formalin steriliser.

Having had an opportunity of seeing the instrument in use it appears to me that Rovsing has placed in the hands of surgeons an instrument of the greatest diagnostic utility and for this reason I am sending these notes to THE LANCET.

Sunderland.

A CASE IN WHICH OCCLUSION OF THE ABDOMINAL AORTA TOOK PLACE.

BY C. H. CATTLE, M.D LOND., F.R C.P. LOND.,
PHYSICIAN TO THE NOTTINGHAM GENERAL HOSPITAL.

COMPLETE occlusion of the abdominal aorta, whether caused by embolus or thrombus, is an event of sufficiently rare occurrence to make the following case worthy of record.

The patient was a man, aged 39 years, who was admitted to the Nottingham General Hospital on May 6th, 1907, complaining of palpitation, shortness of breath, and pain in the region of the heart. These symptoms had been present for 11 weeks. There was no history of rheumatic fever. The patient had had influenza three years ago. His work was very heavy, in an iron-foundry. He was a moderate beer-drinker, and he smoked four ounces of tobacco a week. When he came to the hospital he was of fairly healthy appearance, without obvious cyanosis; the mucous membranes were of good colour, the tongue was clean, and the pulse was 80 and irregular in force and rhythm. The heart's apex was in the fifth interspace, half an inch beyond the nipple line; the impulse was slapping in character. To the right the cardiac dulness corresponded with the right border of the sternum. There was a well-marked presystolic murmur, limited to the region of the heart's impulse, followed by a short first sound. The pulmonary second sound was accentuated. Nothing abnormal was heard in the lungs. The liver and kidneys were normal. There was no œdema of the legs or of other parts.

The patient was kept in bed and he continued to be at absolute rest during the whole of his stay in hospital. A mixture was given containing digitalis and strychnine but the pulse still remained very irregular. The patient complained of some cardiac pain for which a belladonna plaster was applied. His condition was fairly satisfactory until June 17th, when he complained of pain and tenderness in the right iliac region. The temperature rose to 101° F. No swelling could be felt at the seat of pain and in about three days the symptoms had all subsided. On the 23rd the patient complained of pain in the lumbar spine, which during the following night became so intense as to require a hypodermic injection of morphine Soon after the onset of the pain the patient found that he could not move either leg. When seen on the 24th both lower limbs were found to be completely paralysed in their whole extent. There were absolute anæsthesia and analgesia in front from the lower third of the thighs downwards and behind below the fold of the nates. The knee-jerks were absent. The cremasteric reflex was present. There were scattered patches of dusky mottling on the inner aspect of the thighs, the rest of the limbs being strikingly pale and cold. There was complete absence of pulsation in the femorals, the posterior tibials, and the dorsalis pedis. A trace of albumin was found in the urine. The bladder acted normally. On the 25th the mottled lividity of the skin had increased and the anæsthetic area had extended. The urine was dark-red, *containing a* large quantity of blood, showing interference with the renal circulation. On the 26th there were constant hiccough and profuse sweating, death occurring at about 6 P.M. No post-mortem examination was obtained.

The diagnosis of so little-expected an accident as occlusion of the abdominal aorta rested on the absence of pulsation in the arteries of the lower limbs and on their condition of coldness and anæmia with patches of livid mottling. Unfortunately, there was no post-mortem examination but I think there can be no doubt that the diagnosis was correct. Occlusion of the abdominal aorta is fortunately an event which very rarely happens. The author of the article on the condition in Allbutt's "System of Medicine"[1] was able to collect reports of 59 cases, all of which excepting three were fatal. Considerable doubt is permissible as to whether the arrest of the circulation is caused by embolism or by thrombosis. Valvular disease of the heart, especially mitral stenosis, is a fruitful source of embolism, hence it is natural to suppose that embolism of the aorta should occur in the same circumstances as embolism of smaller arteries. The large size of the aorta raises the doubt whether any embolus could be sufficiently large to completely plug it. But an embolus frequently grows in size by the formation of thrombus around it and therefore an embolus arrested at the bifurcation of the aorta might be enlarged in this manner until it filled the lumen of the vessel and extended into both iliacs. The attack of pain in the right iliac region which this patient experienced a few days before the final attack may have been due to a similar cause, whether embolism or thrombosis. The occlusion in this instance cannot have been complete as the symptoms associated with it abated, yet it seems not improbable that an embolus was carried into the right internal iliac, still allowing the circulation to be carried on for a time, and that by gradually extending upwards it eventually caused the obstruction of the aorta. In 34 per cent. of the cases collected by Welch[2] mitral stenosis was present. Mitral stenosis not only provides a possible source of embolus but also often leads to very low arterial blood pressure, which itself is a cause of spontaneous clotting in the vessels. In my patient compensation had quite broken down and it was found impossible by means of rest and cardiac tonics to restore regularity to the pulse or tone to the heart. Hence the circulation was inefficiently maintained, the propulsive force being weak and intermittent. Under these conditions thrombi might very readily be formed in the left cavities of the heart and be the source of an embolus, or it may be that owing to comparative stasis of the circulation primary thrombosis of the aorta or internal iliac occurred. Sometimes the thrombosis is due to extensive atheroma, as in the case reported by the late Mr. W. H. Brown of Leeds.[3]

Whatever the exact pathology of the case the occlusion was evidently complete. The clot probably reached as high as the renal arteries, and this grave interference with the circulation, together with the co-existent cardiac disease, was sufficient to bring about a very rapid termination. But death does not always occur so quickly as in this case. It may be deferred days, weeks, or even months, and be due to gangrene, sepsis, or general exhaustion.

The paraplegia which attends occlusion of the abdominal aorta is doubtless due to the shutting off of the blood-supply. But whether it depends on anæmia of the spinal cord or of the peripheral nerves and muscles is not decided. It is important, therefore, that careful examination of the cord should be made whenever possible.

Nottingham.

THE TREATMENT OF GANGRENE IN STRANGULATED HERNIÆ AT ST. THOMAS'S HOSPITAL, 1901-1905.

BY EDRED M. CORNER, M C CANTAB., F R.C.S. ENG.,
SURGEON IN CHARGE OF OUT-PATIENTS AT ST. THOMAS'S HOSPITAL.

IN the St. Thomas's Hospital Reports of 1900 I published a paper[4] in which was set forth the condition of the bowel found in the strangulated herniæ admitted to the hospital during the ten years 1891-1900. In the present note I wish to direct attention to but one part of the subject of this original communication—the treatment of necrosis of the bowel in strangulated herniæ Since 1900 there have been far more instances of necrosis of the bowel recognised in these cases, giving therefore a better estimate of the present-day treatment than was the case in my original communication. The occurrence of an infective necrosis of the bowel[5] has now been recognised and has led to the more frequent recognition and treatment of the damaged bowel found in strangulated herniæ. In the five years from 1901-1905 necrosis of the bowel has been recognised and treated 30 times, as compared with 42 in the ten preceding years.

Resection and immediate anastomosis.—The balance of the treatment adopted has been in favour of resection and anastomosis of the bowel whenever possible. 18 of such cases have been done with eight recoveries, a recovery rate of 45 per cent. and a mortality of 55 per cent. Thus a great advance has been made on the condition of affairs at the time of the publication of my paper in 1900, when the mortality for the resection of the bowel and anastomosis in gangrenous strangulated herniæ was 80 per cent. It is on account of this very great improvement that I decided to publish this note now, after five years, rather than await the lapse of a decade. There are several reasons which have contributed to this improvement. Firstly, instances of early gangrene or necrosis have been recognised and treated. Secondly, cases where the bowel was only "doubtful" may have been excised, though this must have been infrequent. Thirdly, there are the improvements of modern technique, such as the removal of the bowel widely above the obstruction. A further point of interest is that those cases where the resection of the bowel has been followed by an end-to-end anastomosis, circular enterorrhaphy, have done better than when a lateral anastomosis has been employed.

Resection and enterostomy.—In the same period, 1901-1905, there have been ten cases in which the resection was followed by the making of an artificial anus, an enterostomy, from which there has been only one recovery; recovery rate 10 per cent., mortality 90 per cent.—a result which agrees very closely with the previous finding in 1900, when the mortality was 88·9 per cent. There is certainly one great contributory factor in producing this more or less stationary condition of affairs, which is that the treatment by resection and enterostomy has been reserved only for the very worst cases. Yet in spite of modern advances there has been no improvement in the results. During the same period there has been a diminution by 35 per cent. in the mortality of those cases treated by resection and anastomosis of the bowel. There can be no doubt along which line of treatment modern surgery will progress—resection and anastomosis.

From a surgical and philosophic point of view this is very remarkable, because there is hardly any point upon which abdominal surgeons are so unanimous as that it is far safer to do an anastomosis on healthy bowel than on bowel distended with septic fluid such as it is in intestinal obstruction, an enterostomy at the time and a subsequent anastomosis yielding far better results. Yet in the case of strangulated herniæ the trend of modern opinion is in the opposite direction. There should be a reason for this and I would urge that there probably is a difference in the septicity of the bowel and its contents in cases of intestinal obstruction which have been acute from the beginning, as in the strangulation of a hernia, and when the acute obstruction has merely been imposed on a chronic, as when due to carcinoma of the sigmoid. In the former case the septicity is localised to the vicinity of the obstruction, so that if the resection is done freely more or less healthy tissues will be sutured and success will be attained. And in the latter case the septicity extends further afield and all plastic operations, like anastomoses, are done in a septic area and end in disaster. Then the surgeon, in order to make a successful anastomosis, must either resect so extremely widely that the magnitude of the operation will probably kill a patient, who is already ill, in order to get away from septic bowel and contents, or he must do an enterostomy and having waited for the bowel to have become cleansed and all "endo-enteritis" to have subsided, perform his anastomosis on healthy tissues. This may be the explanation for the very different clinical results obtained by anastomoses made in varieties of intestinal obstruction.

Invagination.—Besides resection with anastomosis or enterostomy two cases have been treated by the invagination of the gangrenous or doubtful area. Both patients recovered and the cases were most successful. The method is obviously applicable only to small areas of necrotic bowel, and in practice will be mainly useful for secluding "doubtful" bowel. But these two cases show that its judicious application has a useful, if not a large, field in the treatment of necrosis of the bowel in hernia. It may be suggested that it is useful at times at the place where the bowel has been "nipped" and also for the patchy gangrene sometimes found at the apex of the strangulated loop. But the dependence of the necrosis on the action of organisms places a bar upon the extended employment of this method which is likely to be more useful as a safeguard for "doubtful" bowel rather than when gangrene or necrosis has already declared itself.

[4] Gangrene in Strangulated Herniæ, &c., St. Thomas's Hospital Reports, 1900.

[5] Clinical Pathological Observations on Acute Abdominal Disease. Constable and Co. 1905.

Mortality.—In 1900 the mortality for the herniæ in the different regions was given. Of umbilical herniæ it was said: "For complicated strangulated herniæ they have the highest mortality of all. A quarter of the cases contain gangrenous bowel." These statements are borne out by the cases in the subsequent hemidecade: of ten cases, only two patients recovered; mortality, 80 per cent. Of strangulated femoral herniæ it was said "a fifth contain gangrenous bowel." Out of 12 cases, four patients recovered; mortality, 65 per cent. Of inguinal herniæ it was said, "generally speaking, they are of much better prognosis than any of the other varieties." A twentieth of the cases admitted contained gangrenous bowel. Of eight cases, five patients recovered; mortality, 37 per cent. Hence it may be said that the cases of 1901–1905 bear out in the more modern treatment all that was said of the different varieties of hernia in 1900.

St. Thomas's Hospital Cases, 1901–1905.

	Mortality.
Complicated strangulated inguinal herniæ	37 per cent.
" " femoral "	66 "
" " umbilical and ventral herniæ	80 "

Of 216 strangulated inguinal herniæ gangrene was recognised in 8	3·6 per cent.
Of 133 strangulated femoral herniæ gangrene was recognised in 12...	9·0 "
Of 46 strangulated umbilical and ventral herniæ gangrene was found in 10	21·7 "

The figures support the contentions made in the previous paper in general, though not entirely in detail. The former percentages for 1891–1900 were 6·1, 19·5, and 25·4 respectively.

Harley-street, W.

A CASE OF DISSECTING ANEURYSM OF THE PULMONARY ARTERY; PATENT DUCTUS ARTERIOSUS; RUPTURE INTO THE PERICARDIUM.

By LESLIE DURNO, M.D. ABERD.;

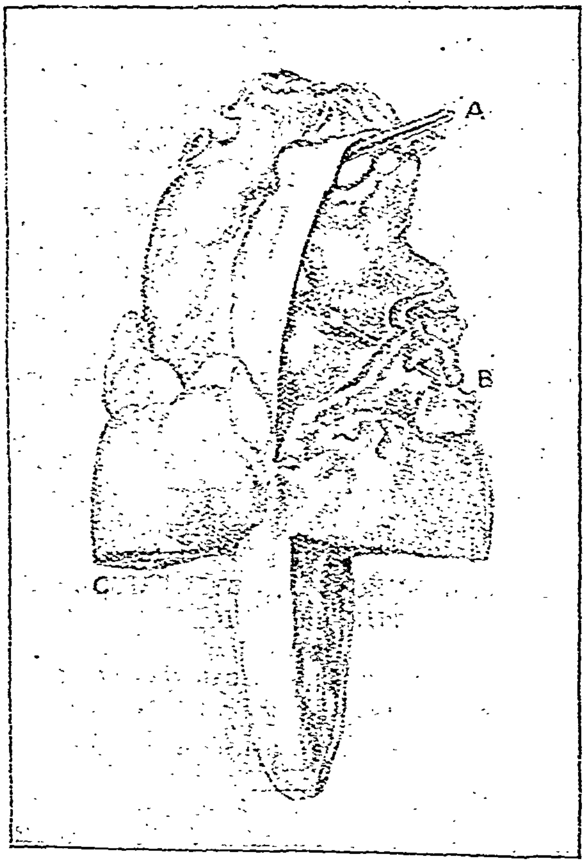
AND

W. LANGDON BROWN, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE METROPOLITAN HOSPITAL; MEDICAL REGISTRAR
AND DEMONSTRATOR OF MORBID ANATOMY AND PHYSIOLOGY,
ST. BARTHOLOMEW'S HOSPITAL.

ANEURYSMS of the pulmonary artery are common enough within the lung as the result of cavity formation in phthisis. But aneurysms of the artery before the lung is reached are very rare. According to Crisp[1] two cases of aneurysm of the main branches were reported in England between 1785 and 1847. He says: "I know of no case of aneurysm of that artery before its division." Dlauhy[2] described a case in 1848. Gilewski[3] found a saccular dilatation of the main trunk as large as a pomegranate. Dowse[4] met with a case of ruptured aneurysm in a girl, aged 19 years; the sac was filled with clot and as there were vegetations on the pulmonary valves it is probable that this was mycotic in origin. Skoda's work on "Auscultation and Percussion" contains an account of an aneurysm of the trunk of the pulmonary artery as large as a goose's egg. Duffield's[5] case of pulmonary regurgitation with aneurysm of the right and left pulmonary arteries resembled ours in the fact that the aneurysm was dissecting in character and had ruptured into the pericardium. It differed in the important particulars of being associated with a lesion of the valve and of beginning in the right branch. Sansom's article in the "Twentieth Century Practice of Medicine"[6] quotes also a case of Crudeli's where there was a general dilatation of the pulmonary artery with small saccular aneurysms above the semilunar valves, one of Sir Dyce Duckworth's associated with congenital malformation of the pulmonary valves, and one of Bruen's associated with congenital malformation of the heart. These are all the instances that we have come across in the literature of the subject.

The patient was a groom, aged 33 years, who appeared to have good health generally. But latterly he had complained that on running a horse he would get out of breath much sooner than usual and had a stuffy feeling in the chest. On severe exertion he would get dusky in colour. Beyond these complaints he was quite able to do his work; he was the father of four children, all healthy. About a fortnight before he died he was attacked with severe pain in his chest and vomited. The medical man who attended him put this condition down to gastritis and treated him accordingly for a fortnight, when the patient declared himself able to resume work. This he did for one day. In the night following that day his wife was awakened out of her sleep by his making noises as if struggling for breath. On trying to give him something to drink she found that he was dead. One of us saw him soon afterwards—about 5.30 A.M.—and found him lying in bed in quite a natural position. The medical man who attended him previously to his death could throw no further light on the subject.

We made a post-mortem examination on the same afternoon. On opening the chest the pericardial sac was found to be distended with about a pint of dark clotted blood. A small hole was found in the pulmonary artery about one and a half inches from its origin, close to the left auricular appendix. The right ventricle was much hypertrophied, the maximum thickness of its outer wall being seven-eighths of an inch (after hardening in formalin), while the maximum



The dilated pulmonary artery is laid open, showing the patches of atheroma. The rod A is passed through the patent ductus arteriosus, close to which a small saccular aneurysm is seen. Under the arrow a tear in the wall of the artery can be seen, starting from the right branch of the pulmonary artery and rupturing into the pericardium close to the head of the arrow at B. The ventricular walls have been cut away so as to expose the great thickness of the right side, which can be seen at C.

thickness of the left side was half an inch. The ductus arteriosus was widely patent, its walls being atheromatous. The pulmonary artery and its two main branches were dilated uniformly, the walls showing large plaques of atheroma. Just before the ductus arteriosus was reached there was a little saccular aneurysm about as large as a filbert. At the bifurcation of the pulmonary artery into its two divisions the intima and media were torn right through. A dissecting aneurysm had formed which contained a small amount of blood clot. This aneurysm had burst into the pericardium. All the other viscera were greatly congested, but no other lesion could be found, except that perhaps the capsules of the kidneys were slightly adherent.

Remarks.—The sequence of events would seem to have been as follows:—

1. The patency of the ductus arteriosus made it necessary if the pulmonary circulation was to be duly maintained for the pressure in the right side of the heart to rise till it was equal to that of the left. Therefore the right ventricle was compelled to hypertrophy. Normally the pressure in the aorta is about 150 millimetres of mercury, while that of the pulmonary artery is only 60 millimetres; consequently the resultant hypertrophy was very considerable.

2. The artery became atheromatous. Whether high pressure is a cause of atheroma is a disputed point. The experimental production of atheroma by injections of adrenalin has been held to prove this, but it seems doubtful whether sufficient control examinations have been made of the condition of the arteries in animals in which no such injections have been made.[7] The occurrence of atheroma in a man aged 33 years in the pulmonary artery is, in the circumstances, very suggestive of high pressure causing the atheroma. In this case the vessel must have been exposed to a pressure more than double the normal. It is not uncommon for a patent ductus arteriosus to become atheromatous. Darwin's law of the liability of vestigial structures to disease is here again exemplified.

3. The atheroma and high pressure combined produced a dissecting aneurysm which, as usual, took the form of a sharp transverse tear near the origin of the vessel. This was probably the cause of the pain which attacked him a fortnight before his death. It is not uncommon for a dissecting aneurysm to be accompanied by vomiting.

4. The blood extravasated between the coats ultimately burst into the pericardium, this accident being in all probability accelerated by his return to work. Extravasation of blood into the pericardium is a well-known cause of sudden death, for the heart, while very tolerant of interference with its systolic output, is extremely intolerant of any interference with its diastolic filling.

A CASE OF PNEUMOCOCCAL MENINGITIS.

By ALEXANDER J. KENDREW, L.R.C.P. LOND., M.R.C.S. ENG.,

SENIOR HOUSE PHYSICIAN, METROPOLITAN HOSPITAL, KINGSLAND ROAD, N.E.

THE patient in the case now described was a male child, aged seven months, and was admitted to the Metropolitan Hospital under the care of Dr. W. Langdon Brown at 6 P.M. on May 9th, 1908. The mother brought him because she had noticed that "since May 3rd the child had seemed a little off colour and that on the 9th the child appeared to have pain in the back whenever he was lifted up." The mother had had an easy labour at the birth of the child who was carried to full term and was breast fed. He suffered from bronchitis at the age of six weeks and from chicken-pox at the age of five months, but never had any discharge from the ears. The family history had no bearing on the illness. On arrival at the hospital the child was found to be well-nourished and was not crying. The fontanelle was widely open, very tense, and bulging. The child was not blind; the pupils were equal and reacted to light. There was an external squint of the left eye. The ears appeared to be natural and there was no discharge from them. The chest was natural; the abdomen was also natural, being neither distended nor retracted. The abdominal reflexes were obtained on both sides. The legs were very rigid; the knees could only be flexed with difficulty and the thighs could scarcely be flexed at all. Kernig's sign was therefore not obtainable, since the thighs could not be flexed even when the knees were already flexed. The plantar reflexes were extensor on both sides. Lumbar puncture was performed on admission, one test-tube full of clear fluid being withdrawn. Chemical examination showed that this fluid contained reducing sugar and much albumin. On microscopical examination 330 leucocytes per cubic millimetre were found, the majority being polymorphonuclear. Cultivation on serum agar gave in 18 hours a growth of a Gram-positive diplococcus. On the next day the child had fits which continued until his death at 2.30 on May 11th. His temperature at the time of death was 105·6° F. A second lumbar puncture was made just before death; the fluid then withdrawn was turbid and yielded a pure culture of the pneumococcus.

At the necropsy the body was seen to be well developed. In the skull a little pus was present on the internal surface of the dura mater in several places at the vertex and at one spot opposite the pole of the left temporo-sphenoidal lobe. At this spot the dura mater was roughened but on peeling it off the bone appeared to be quite healthy, as indeed it appeared to be everywhere. Both of the internal ears contained a little viscid mucus but no pus. In the brain a thick layer of greenish-yellow pus could be seen under the arachnoid covering the whole of both frontal lobes and extending backwards on to both parietal regions. Behind the fissures of Rolando the pus lessened in amount and was only present in small scattered patches on the parieto-occipital regions. Both temporo-sphenoidal poles were covered with pus, which also filled the Sylvian fissures. At the base the pus was situated in and around the interpeduncular space and optic chiasma. The arachnoid covering the pons was only slightly opaque while that over the medulla oblongata was unaffected. The blood-vessels behind the pus-covered area were considerably congested. The convolutions on the surface were much flattened but the brain was not cut into as it was preserved entire. The spinal cord appeared to be natural; a little pus was present outside the dura mater in the dorsal and lumbar regions but there was none within the membranes. All the other organs in the body appeared to be natural.

In a paper published in THE LANCET of Oct. 8th, 1904, p. 1017, by Dr. A. T. Davies and Dr. Langdon Brown, I see that it is said: "Probably not pneumonia only but all pneumococcal infections tend to be septicæmic. Thus at St. Bartholomew's Hospital during the last ten years 17 cases of meningitis without discoverable lesion elsewhere were proved to be pneumococcal. In three instances cultures of the spleen yielded a pure growth of pneumococci." In the present case it seems to me that this child must have had a septicæmia. It is unthinkable that the meninges could be the only, or even the primary, seat of infection.

I am much indebted to Dr. Langdon Brown for permission to publish these notes, and also to Mr. Ernest H. Shaw, pathologist to the hospital, for help in the bacteriological and post-mortem work.

Metropolitan Hospital.

NOTE ON A CASE IN WHICH THE WIDAL REACTION PERSISTED SEVEN YEARS AFTER AN ATTACK OF TYPHOID FEVER;

ASSOCIATED WITH SUPPURATIVE CHOLANGITIS, TYPHOID BACILLI BEING FOUND IN THE BILE PASSAGES.

By DONALD E. CORE, M.B., CH.B. VICT.,

HOUSE PHYSICIAN AT THE DERBYSHIRE ROYAL INFIRMARY, DERBY.

THE patient came into the Derbyshire Royal Infirmary suffering from jaundice and periodical attacks of shivering. She had been ill for five weeks and the trouble began with a paroxysm of intense pain, which was diagnosed at the time as gall-stone colic. Since that time she had wasted steadily and lost strength. There was no history of diarrhœa. She had had typhoid fever seven years before.

On admission the patient, who was a stout, somewhat flabby woman, had a temperature of 101·4° F. and a pulse-rate of 132. The respirations were 32. She was very listless, lay flat on her back, and was distinctly jaundiced. The tongue was dirty and very dry, and the abdomen, though not tender on palpation, was distended. The liver was enlarged, the lower edge being depressed fully three fingers' breadth below the costal margin. No irregularities could be made out on its surface. The spleen could not be felt when she was admitted but it became palpable on the fifth day. There were no rose spots. The heart was dilated and no apex impulse was visible or palpable. The area of cardiac dulness extended fully an inch to the left of the left nipple line. To the right, dulness extended half an inch to the right of the sternum; above it reached to the top of the third rib. A marked canter rhythm was heard all over the cardiac area, the first sound being accentuated and the second reduplicated. This rhythm was most evident at the apex. Ten days after admission the reduplication of the second sound disappeared, its place being taken by a soft systolic murmur conducted outwards into the axilla. The breath sounds were normal in character and there was no evidence of consolidation anywhere. Moist sounds were audible over the bases.

---

[7] Miles: Journal of the American Medical Association, Oct. 5th, 1907.

On the day after admission the temperature rose to 102·8°, and for the next five days it varied between 99° and 100°, the daily excursions being remarkably uniform. On the sixth day it rose to 101·8° and fell gradually to the normal during the next two days. On the eleventh day it was 101·2°, falling to 99° on the next morning; on the evening of this day it rose to 102° and fell to 98° on the day following. On the day on which death occurred it rose to 103°, dropping immediately to 95·6°. The cardiac dilatation rapidly subsided with the rest in bed and the pulse became more regular. During the first eight days it varied between 132 and 116; then it became steadier and ranged between 80 and 60. The patient, however, did not show any improvement in her general condition, but became more and more asthenic. Throughout the whole of the time that she was under observation in the hospital this was a very marked feature of her condition; she did not show the improvement in her general state that might have been expected from the physical signs. Constipation was obstinate all the time that the patient was in the hospital, the stools being clay-coloured. The urine contained neither albumin nor bile. During the last two days of life persistent and intractable vomiting set in, the patient not being able to keep even albumin water in her stomach. From the day of her admission there had been mild delirium at night and this became intensified during her last few days. Death occurred on the fourteenth day after her admission.

On opening the abdomen post mortem the first object that attracted attention was the liver, which was enlarged and studded with brownish-yellow nodules that fluctuated on pressure. On closer examination the great omentum was found to be adherent to the gall-bladder and could only be detached by tearing this latter structure. On section a thick creamy substance of a bright orange-yellow colour oozed from the bile-ducts, which were thickened and distended. This was universal over the whole organ. The contents of the gall-bladder were normal in colour and the ducts did not show any stenosis; the gall-bladder contained a gall-stone. The liver weighed five pounds. There were no typhoid lesions found in the intestines; the spleen was somewhat enlarged. The other organs were normal, there being no signs of endocarditis. The pus, taken from the intrahepatic bile-passages, showed both culturally and on films the presence of the bacillus typhosus in large numbers.

I have ventured to record this case as possessing some interest not only on account of the patient's probable rôle of a typhoid carrier, but also because it also shows that the Widal serum reaction may persist as long as seven years after the attack of typhoid fever. Professor Hewlett, in his "Text-book on Pathology," states that "the reaction of agglutination once acquired, may persist for years—certainly three or four." In this case there was a most clear and convincing account of typhoid fever seven years before the patient was admitted into the hospital, and the reaction was accountable for a not unnatural difficulty in the diagnosis. The patient was admitted as a case of typhoid fever, and yet there were not many symptoms, apart from the serum reaction, which pointed to this disease. The enlarged liver and jaundiced aspect at first gave rise to the idea that she was suffering from cholangitis, with the possibility of ulcerative endocarditis; when, however, the result of the serum reaction became known we considered it to be, and treated it as, a case of typhoid fever. Nevertheless, we realised that there were many atypical symptoms, and we were not altogether satisfied with this diagnosis. Had we known that it was possible for the serum reaction to persist for seven years after the attack which gave rise to it, I do not think that we should have held to this diagnosis at all.

The second point of interest shown by the case is one which has had a great deal of attention directed to it lately—namely, the danger to a community from having such a patient as this in its midst. This woman must have been discharging typhoid bacilli more or less continuously for seven years, and recent evidence has conclusively proved that her case was in no way unique. The early recognition of such cases appears to be imperative in any crusade against typhoid fever, and it would be instructive to know what connexion, if any, a persistent Widal reaction has with persistence of typhoid bacilli in the organism.

I am indebted to Dr. M. Parry-Jones for giving me permission to publish this case.

Derbyshire Royal Infirmary.

Reviews and Notices of Books.

Comparative Anatomy of Vertebrates. Adapted from the German of Dr. R. WIEDERSHEIM by Dr. W. N. PARKER. Third edition. London: Macmillan and Co. 1907. Pp. 576. Price 16*s.* net.

THE last English edition of this book appeared in 1897 and was based on Professor Wiedersheim's "Grundriss der Vergleichende Anatomie der Wirbelthiere." There has been an interval of ten years, therefore, between the publication of that edition and the appearance of the present volume which is adapted from the "Grundriss" of 1906 and, as may be supposed, the growth of our knowledge of comparative anatomy during those ten years has made it necessary, even with the most careful condensation, to increase the size of the work by nearly 100 pages.

The introductory chapter gives a definition of the various minor branches which make up the complete science of comparative anatomy. We are glad, by the way, to see the old-fashioned name retained because, though many modern animal morphologists are inclined to look down upon it, comparative anatomy has a very real meaning apart from old associations and has never been adequately replaced by any other name. A brief outline of the chief details of embryology succeeds, followed by a general review of the chief organs and systems of the vertebrata. This is illustrated by a diagrammatic scheme of a sagittal section of a generalised vertebrate, which is new and would be more valuable if the duodenal loop were directed ventrally instead of dorsally and the spleen placed in the dorsal instead of the ventral mesentery. Moreover, the pancreas might have shown one or more ducts in the same way that the bile-duct is shown. The classificatory and palæontological tables remain as in former editions and are most valuable for reference.

The chapter on the integument has several new and useful process illustrations, but it is doubtful whether it would not have been more convenient to treat it and the exoskeleton together; at any rate, we cannot agree with the author when, on p. 43, he includes the abdominal ribs of Hatteria (now usually known as Sphenodon) and of the crocodile among exoskeletal structures. Again, on the next page he says in a footnote that the mammalian sternum may include some vestiges of the exoskeletal episternum. If he does this he should surely be consistent and give mammals credit here for having exoskeletal vestiges in the roof of the cranium and bones of the face, as well as in the sternum. We should like to know why the author casts a doubt on the perfect homology of the intercentra of mammals with those of other vertebrates. Boulenger has shown how common they are in lizards, while similar traces can be found in many mammals. Unless the author denies the serial homology of these structures with the ventral arch of the atlas he is practically throwing out a suggestion that the ventral arch of the atlas in mammals is not homologous with that of reptiles and birds, yet he says on p. 62 that the atlas and axis of mammals essentially resemble those of birds.

In the skull some excellent new illustrations are added and the chapter forms a good and clear introduction to the study of this difficult subject. The limb bones, too, are fairly dealt with except that we look in vain for some discussion on the very important question of the nature and uses of epiphyses; indeed, in the index, epiphyses of long bones are not even mentioned. On p. 172 it is stated that the patella is in no way comparable to the oleolecranon (*sic*) of the ulna as was formerly supposed. This appears to us a drastic statement and one on which we should be grateful for some reasoning. It certainly is opposed to some modern research which has not been noticed.

The nervous system has been well overhauled and the enormous literature on the pineal region and nerve components has been done as much justice to as space would permit. We notice, however, that one page is still all that is allotted to the spinal cord and that few additions to the description of this region have been made with the exception of a footnote on Reissner's fibre. The vascular and genital apparatus are done ample justice to, but so far as their embryology is concerned cannot be said to be well up to date. The omissions, however, are seldom of first-rate importance.

The appendix on the literature of the subject is a most valuable part of this book and is as exhaustive as can fairly be expected when the size of the work is considered. There are, it is true, several modern papers which might with advantage have been added even at the expense of leaving out some of the older ones, because these are always referred to in the newer. We think that it would aid reference if the names of the subjects with which the papers deal—e.g., skull, nervous system, and so on—were printed on the top of each page, and perhaps this suggestion may be adopted in subsequent editions.

We have no hesitation in commending this book to teachers and to students alike. It is well written, well got up, and abundantly illustrated. The immense mass of facts is digested and arranged with a master's skill, and, if the work tends to err on the side of too dogmatic statements, it is a fault which the student will be thankful for and the research worker will view with a very lenient eye, for, in the present stage of morphology, to day's nay is often to-morrow's yea.

The Cradle of the Deep, an Account of a Voyage to the West Indies. By Sir FREDERICK TREVES, Bart., G.C.V.O., C.B., LL.D., Serjeant-Surgeon to H.M. the King. With numerous illustrations and one coloured plate. London: Smith, Elder, and Co. 1908. Pp. 374. Price 12*s.* net.

IN certain of the natural gardens of the West Indian archipelago there is to be found a tree of such extreme beauty as to attract the traveller's notice amongst a confusion of splendid rivals. Its leaves are of an exquisite green and graceful shape and it is thickly hung with bright scarlet globes which when they have ripened afford a wholesome food of delicate flavour. This is the akké fruit which has one peculiarity, that beneath its outward beauty, before the ripening process is complete, there lurks a sufficient amount of prussic acid to kill the man who unwarily partakes of it. The akké tree stands as a fitting type of the lands that give it nourishment, lands of a transcendent fairness which has captivated the imagination of travellers since first they broke upon European eyes, and which has yet formed the background for manifestations of cataclysmal cruelty of nature and of murder, rapine, and lust of man, such as perhaps the history of no other region in the world can equal.

The latest addition to the many books of travel which seek to set forth the wonder and the tragedy of the West Indies is from the pen of Sir Frederick Treves. Many of our readers will remember his record of impressions gathered in Eastern lands, and to those who have enjoyed them we may say at once that Sir Frederick Treves has greatly surpassed that achievement in the present admirable volume. Although his chapters are strung upon the itinerary of a prosaic "circular tour" of the Antilles and the Spanish Main, there is nothing whatever in them to suggest the globe-trotter's diary, but there is very much that bears witness to an eye of singular acuteness, backed by a living imagination and a ready wit; and there is no better proof of this than the poor impression which his photographic illustrations give by comparison with his text, although many of them are technically excellent. The book itself has a vividness that almost suggests a kinematographic record of faithfully coloured pictures, and as in such displays we are generally whirled from one set of events to another with startling suddenness, so does this writer make us change our outlook from a crowded modern quayside or the streets of a dreaming Spanish town to the quarterdeck of Drake's galleon, the assault on a treasure-stocked stronghold, or the blood-stained march of Morgan's desperadoes. Indeed, the traveller may well envy the author his faculty of peopling the places which he visits from out of the sleeping centuries; though they are scarcely ghosts which pass before us on his screen, but rather living, fighting, swearing men, cut-throats, heroes, and buccaneers, summoned up in the garb and fashion in which they lived their desperate lives. No less successful are his pictures of an antique polite and official world, the fine gentlemen of the colonies who, when buccaneer or chartered pirate was not engaged in sacking their towns, strutted their parts in the West Indian islands of the seventeenth century as bravely as any brother gallants on the Mall at home. We may instance the peep which he gives us at "St. Kitts in all its glory." But it is in the darker side of the picture that his descriptive force appears most strongly, a force that would seem at times almost too brutal were it not for the nearly unimaginable horrors upon which it is expended, the wiping out of Martinique by the death-cloud from St. Pierre, the destruction of Kingston, the ancient atrocities of the Gold Road in Panama, along which the buccaneers flogged their toiling slaves. This last chapter alone should earn the book a distinctive place in the English literature of travel, and very fascinating are those brighter pages in which the author tells of certain exploits of English ships and arms upon the Spanish Main, notably his magnificent story of "No Flint" Gray and "H.M.S. *Diamond Rock.*" It is in reference to such heroic feats that he has named his book "The Cradle of the Deep," for, as he explains, "in the seclusion of those gorgeous islands, indeed, the long sea story of England was begun. The West Indies became the nursery of the British Navy, the school where the thews were hardened and the sea lessons learned."

But it must not be supposed that Sir Frederick Treves has no eye for the gracious side of his subject. We could quote many passages to show his appreciation of the wonderful beauty of the West Indies; such chapters as "The High Woods" of Trinidad breathe its very spirit and the allurements of many other islands receive their fair share of a praise which never gets out of hand, for although the author can people the places which he has seen with imaginations of the past he does not employ his fancy to over-embroider his descriptions of what he has seen, as over-enthusiastic travellers are prone to do. But when he is able to bestow complete admiration he can do so in such wise as in this description of his first sight of the humming-birds which must commend itself irresistibly to all who have shared his joy of watching them in their native gardens:—

> They came from all sides; tiny winged wonders of blue, green, and gold, that for a moment one took to be great bees. They were so capricious, so alert, so quick as to be hard to follow. They sucked the honey from each flower while on the wing. They hung before the scarlet calyx in an ecstasy of worship, each little suppliant a whirl of green and gold. The vibrating wings could not be seen. There was merely a poised palpitating body with a dizzy halo on either side of it. It was not until they rested, with shut wings, on a spray near by, that they turned to birds again.

That is admirably seen and admirably written, and we could quote many equal passages.

We have little to find fault with in the book, except the statement on p. 12 that the English straw hat is the only head-covering required in any West Indian island. A prolonged stay in their lowlands would convert most people to the advantage of the sun-helmets which he scorns but which are worn frequently by the inhabitants. We also regret that the author's tour did not include a ride up the Blue Mountains of Jamaica. He would have found in them a worthy theme for the very able powers of description which he shows throughout "The Cradle of the Deep." We cannot finish our review of a book which we have enjoyed greatly without paying a tribute to the admirable humour of the chapter on "Saba the Astonishing," and we should much like to know if we may really believe it all, for it tells of an island that outdoes the conceptions of the most irresponsible comic opera.

A Text book of Surgical Anatomy. By WILLIAM FRANCIS CAMPBELL, M.D., Professor of Anatomy, Long Island College Hospital, Attending Surgeon to the Methodist Episcopal, Swedish, and Bushwick Hospitals; Consulting Surgeon to the Jamaica Hospital. With 319 original illustrations. London and Philadelphia: W. B. Saunders Company. 1908. Pp. 675. Price 21*s.* net.

THE scope of surgical anatomy varies greatly with the choice of the writer; with some it is merely that portion of anatomy a knowledge of which is especially needed by surgeons, but with others it includes not only this amount of anatomy but also some pathology, and occasionally even treatment. The value of these extensions of the original scope of works on surgical anatomy depends greatly on the author, and though Dr. Campbell appears to us to have included much that is not usually to be found in a book claiming to deal with surgical anatomy, yet he has written so well that we cannot complain. The book is excellent and there is little to which exception can be taken. The author appears to attach undue importance to the parathyroid glands and they hardly deserve the page that is devoted to them. We cannot agree with Dr. Campbell when he says that in transverse fractures of the patella, "all forms of treatment except open operation must result in fibrous union because of the fibrous curtain which has dropped between the fragments." We agree that the open operation is the best but subcutaneous wiring and even splinting methods may result in bony union. The book is well provided with illustrations.

Squint and Ocular Paralysis. By E. LUCAS HUGHES, M.R.C.S. Eng., L.R.C.P. Lond., Fellow of the Royal Institute of Public Health; Clinical Ophthalmic Assistant, Royal Infirmary, Liverpool. London: H. K. Lewis. 1907. Pp. 206. Price 6*s.* 6*d.* net.

SQUINT and disorders of mobility of the eye appear to exercise an extraordinary fascination upon students of ophthalmology, leading them to rush into print upon the slightest provocation or even without any encouragement at all. The present work is better than the majority, for it deals less with personal fads founded upon uncontrolled theorisation and gives credit to those to whom it is due, particularly to the real founders of the orthoptic method of treatment, Javal and Parinaud. This is doubtless due to the author's work as a clinical assistant in Paris, which has also led him to describe and to explain the uses of Rémy's diploscope, an instrument which is seldom referred to in English text-books. Mr. Hughes is, of course, an enthusiast; *cela va sans dire.* He is a whole-hearted disciple of the orthoptic school and we are not surprised to find that his enthusiasm outruns discretion. We do not agree with the statement that "with persevering orthoptic treatment, especially under the age of seven, strabismus, instead of rarely, may be said to commonly disappear of itself." We do not wish for a moment to undervalue this method of treatment in suitably selected cases, but we are convinced that it has been grossly overrated in the past and that its proper sphere of influence is likely to be obscured by the injudicious attitude which is so common in matters of this kind and is so much to be deprecated. The author has not neglected the work of English observers, notably Maddox and Worth; indeed, it appears to us that he has borrowed with much freedom from the writings of the latter author. The discussion of ocular paralyses follows the usual lines and contains nothing that will not be found in the ordinary text-books. The same may be said of the chapter on disturbances of muscle balance. We have already expressed the opinion that the book is better than most of the specimens of its class, and as such it can be confidently recommended to the student as a good introduction to this branch of ophthalmology.

LIBRARY TABLE.

Ueber Abdominale Totalexstirpation des Myomatösen Uterus. Von M. GRAEFE. Halle: Carl Marhold. 1907. Pp. 33. Price M.0·8.—In this paper Dr. Graefe discusses the question of total extirpation or removal by supravaginal amputation of the uterus containing fibroid tumours. Personally he favours the former operation and he brings forward the usual arguments in favour of his view. The matter is essentially one which each operator must settle for himself and which must, moreover, often depend on the exact conditions found at the time of the operation. Those surgeons who dread the subsequent occurrence of carcinoma of the stump of the cervix, and Dr. Graefe has himself collected 14 cases of this kind, will take care to remove the whole uterus. He does not believe that the objections hold good that total removal of the uterus leads to shortening of the vagina or endangers the functions of the pelvic floor, and he has not seen any such bad results follow this operation. At the same time it must be remembered that no operator has ever obtained such good results after total extirpation as those recorded by Zweifel—namely, 201 operations of supravaginal amputations with only one death. The author has performed total extirpation in 33 cases and he records the results of these operations as well as of 11 performed under similar conditions by his colleague, Dr. Wittauer, or a total of 44 cases with four deaths. Two of these he claims were not the result of the operation, giving a total mortality of 4·8 per cent. The question is one which time alone will settle and for our part the author does not convince us that the opinion that supravaginal amputation is preferable in the majority of such cases is a wrong one, nor do we imagine that he will succeed in converting to his view any other advocate of this eminently satisfactory operation.

Manual of Diseases of the Ear, Nose, and Throat. By JOHN JOHNSON KYLE, B.S., M.D., Professor of Clinical Otology, Rhinology, and Laryngology in the Medical College of Indiana, Department of Medicine at Purdue University; Otologist, Rhinologist, and Laryngologist to City Hospital, St. Vincent's Hospital and Dispensary, Indianapolis. Second edition, revised and enlarged. With 169 illustrations. London: Sidney Appleton. 1908. Pp. 627. Price 12*s.* 6*d.*

net.—The first hundred pages consist of a brief review of the embryology of the ear, nose, and throat, and the anatomy and physiology of the ear, the nose, nasal fossæ, accessory sinuses, and trachea, with the bacteriology and pathology of the ear, nose, and throat. The methods of examination, special instruments, and therapy, including a very large number of prescriptions, occupy the next 70 pages. Chapter IX. deals with diseases of the external ear and the next chapter is devoted to diseases of the middle ear, including injuries. We notice that Dr. Kyle has included in his work a short account of the work done by Escat and Alexander with regard to the effect of arteriosclerosis on the labyrinth; for treatment he recommends iodide of potassium The chapter on diseases of the nose is, like the preceding one, very full, especially considering the size of the book. Nasal polypi are, however, termed "myxomata." There is a very minute description of the submucous operation on the nasal septum which we think will be found very useful. Diseases of the oro-pharynx and pharynx, which are made to include diphtheria and diseases of the larynx, contain very good descriptions of all the various diseases. Although this work cannot be said to present very many subjects in a new light, still it is an extremely useful and valuable addition to books of a moderate size available for the use of practitioners of general medicine. It is extremely well written, the illustrations are very good, and it is a work which we believe will prove of great service to those who are too busy to have recourse to larger books.

JOURNALS AND MAGAZINES.

The Edinburgh Medical Journal.—In the May number Dr. James M. Beattie writes on acute rheumatism and details the evidence in favour of its bacterial origin. Under the title of "The Eclectic Treatment of Skin Diseases" Dr. W. Allan Jamieson reviews the work of Unna, now set out in detail in the monumental treatise of his pupil, Dr. Iwan Bloch. Professor Harvey Littlejohn and Dr. J. H. H. Pirie discuss micro-chemical tests for semen, the most hopeful being Barberio's picric acid reagent. Lieutenant-Colonel W. B. Bannerman, I.M.S., gives an account of recent researches into the causation of plague in India and concludes that infection is conveyed both from rat to rat and from rat to man solely by the agency of the rat flea.

The Scottish Medical and Surgical Journal.—In the May issue Dr. A. H. F. Barbour concludes his discussion of the evidence of frozen sections on the question of the lower uterine segment, and maintains that recent investigations do not tend to alter the accepted view. Miss Anne Mercer Watson writes on medical inspection of schools and criticises a recent memorandum from the Education Office with considerable severity. Dr. Stuart M'Donald reviews the position of pathology in the new curriculum of the University of Edinburgh and deplores its separation from practical medicine—a separation which has been effected at other seats of learning with very doubtful advantage. Some clinical notes by Dr. John Gordon deal with a case of vesicular eruption produced by a preparation called zambuk and with the alarming effects of a cantharides blister applied for sciatica; and Dr. J. Eason records some good results obtained in the eczema of infants and young children by thyroid substance.

The Medical Chronicle.—In an article on hydrocele in children Mr. E. D. Telford writes as follows: "A hydrocele if left to itself will eventually undergo an apparently complete cure;" while later he says that a certain "operation, if carried out in a series of hydroceles, will yield another argument for its adoption"—i.e., the credit for relieving a condition which would have disappeared spontaneously will be given to the operation and used as an argument for further proceedings of the same kind. We do not know if this is meant to be sarcastic or serious. Dr. Frank E. Tylecote narrates a case of post-typhoid furunculosis which yielded to vaccine treatment. An abstract of recent work by Professor von Noorden on nephritis is contributed by Dr. W. B. Warrington.

The Dublin Journal of Medical Science.—Dr. Walter G. Smith's contributions on chemical subjects are always interesting and the paper on clinical examination of the urine appearing in the May number of this journal is no exception to the rule. He constructs a urinary catechism, the questions in which may not seem any too simple even to those who are fairly familiar with the composition of the urine. "M.D. Theses," by Dr. Thomas O. Graham on epidemic diarrhœa and by Dr. T. J. Townsend Wilmot on syphilitic affections of the eye, appear in the same number.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE session of the General Medical Council lasted until late on Wednesday afternoon, the unusual length of the sitting being due to the exhaustive hearing of the Catford case.

On Tuesday the following committees of the Council, in addition to those published in THE LANCET last week, were nominated:—

The Finance Committee, consisting of Mr. Tomes (chairman), Mr. Morris, Sir John Tuke, and Dr. Little.

The Dental Committee, consisting of the President, Mr. Morris, Mr. Tomes, Mr. Hodsdon, and Sir Thomas Myles.

The Dental Education and Examination Committee, consisting of Mr. Tomes, the President, Mr. Morris, Dr. Lindsay Steven, Dr. Finlay, Sir Thomas Myles, and Sir Charles Ball.

The Students' Registration Committee consisting of Sir Hugh Beevor, Dr. Norman Moore, Sir C. Nixon, Sir John Tuke, Dr. Adye-Curran, and Dr. Mackay.

We continue our report of the Catford case at the point at which we broke off last week.

MONDAY, JUNE 1ST.

The Catford Case.

Mr. HEMMING at the outset handed in an objection which the legal assessor perused.

Mr. LUSHINGTON: I can see that this is a protest against the attitude of the legal assessor and I do not think I ought to state it myself. I will hand it to the President.

The PRESIDENT said that this was not an objection but a protest. It was suggested that interruptions had been made with an object not favourable to the accused practitioner. The protest was not an objection and would be placed on record but it had no bearing on the future proceedings of the Council.

Dr. MCVAIL: You say it will be placed on record. Must that not be subject to the permission of the Council?

The PRESIDENT: We will consider that *in camerâ.*

Nurse PARKER, who is engaged at the London Hospital, was, by leave of the Council, then called as a witness. She spoke as to the attendance of Mr. Nicolas at a case at Thornton Heath on a date in April, 1907, on which one witness alleged he was in Catford.

Mr. HOWARD WALLACE, shipbroker, 85, Downhill-road, Catford, as a neighbour of Mr. Nicolas, stated that the latter did not take up his residence in Downhill-road until April 8th, 1907.

Mrs. ELLIS denied certain allegations made by a previous witness as to canvassing.

A succession of witnesses entered the witness-box. They were all acquainted with Mr. Nicolas. They denied that he had canvassed them and contradicted previous allegations.

Mrs. ROSE RIMMELL stated that she had formerly been a patient of Mr. Atkinson. She had taken in Mr. Nicolas as her doctor, because he had saved the life of herself and her little girl. She had not been canvassed by Mr. Nicolas but had called him in on her own accord.

Mrs. GALVIN, a widow, stated that she had taken a document round the neighbourhood and in one day had got it signed by 82 persons who were patients of Mr. Nicolas. By signing the document those persons stated that they had not been canvassed nor had they heard Mr. Nicolas say anything disparaging of Mr. Atkinson.

Mr. HEMMING asked leave to hand in the document.

Mr. NEILSON asked how far documents of this sort were admissible in the Council's procedure. If the Council did not admit them in the ordinary form he would take objection to this document.

Mr. HEMMING pointed out that Mr. Nicolas was charged with systematic canvassing. By what method could Mr. Nicolas meet the charge? He could meet it by an *alibi*, or by a general denial supported in this way, or by his own denial. He produced the signatures of a large number of people who had signed the document that they had not been canvassed by Mr. Nicolas. If he could not meet the charge in that way how could he do it at all? There must be some way of holding a due inquiry. He could not subpœna these people. The Council had no power to issue a subpœna. He could not compel them to attend and give evidence.

Mr. LUSHINGTON said that the Council so far as possible regulated its procedure by that in a court of law. However, they were in this difficulty, because they had no power to compel the attendance of witnesses, or to put them on their oath, or to use ways by which courts of law could reinforce their methods of dealing with witnesses. In this case he was inclined to advise the Council to admit this document. He should point out to the Council what in his opinion it was worth. He added that the best evidence the Council could have was that of Mr. John Papa Nicolas to show whether there was anything in the case or not. In the meantime he would take in the document.

Mrs. GALVIN, cross-examined by Mr. Neilson, maintained that nobody asked her to take round the document; the idea of it came into her head by itself.

In answer to Mr. LUSHINGTON she stated that she had been supplied with no list of people. She went on her own accord to get up the signed petition. Mr. Hemming never came to her about it nor anyone from him.

Mr. HEMMING then went into the witness-box and stated that Mrs. Galvin came to him and said that she had heard Mr. Atkinson was proceeding against Mr. Nicolas. She suggested a petition. Mr. Hemming prepared it at her request and to that extent it was his document. He had prepared it just as if anyone had asked him to write a letter. He did not supply the list of names.

Mr. JOHN PAPA NICOLAS then proceeded with evidence in his own behalf. He handed in ten certificates testifying to character and professional ability.

Mr. HEMMING: Have you ever canvassed for patients?

Mr. NICOLAS: No.

Mr. HEMMING: Have you ever disparaged Mr. Atkinson?

Mr. NICOLAS: No.

Mr. HEMMING: Have you ever praised Mr. Atkinson up?

Mr. NICOLAS: Yes. Witness went on to state that he first had been assistant to Mr. Hugh Latimer Atkinson, the brother of Mr. Thomas William Atkinson. He was some time afterwards asked to go as assistant to the latter at Catford. After negotiation he went at a salary of £180 a year.

Mr. HEMMING: Was there anything said about signing a bond or agreement then?

Mr. NICOLAS: No. He went on to say that Mr. Atkinson attended the better class patients. He liked to pay the first visit to patients himself when possible.

Mr. HEMMING: When you had been with Mr. Atkinson for some time did you suggest leaving him?

Mr. NICOLAS: When I had been with him for about nine months I was one day at his surgery at his private house and when I was making up some medicine he asked what I was meaning to do as time was going on. I said I had really not made up my mind and I wanted to know something about an increase of salary or a partnership. He said that he was quite satisfied with me and he would think about the partnership himself, and he wanted me to stay two or three months at a salary of £200 a year. Then he said he would like to have a bond. I said, "No; I do not see the need for having a bond."

Mr. HEMMING: Who first mentioned the bond?

Mr. NICOLAS: Mr. Atkinson. He left Mr. Atkinson shortly afterwards to go abroad on private business.

Mr. HEMMING: At this time what was the relationship between you and Mr. Atkinson with reference to two points: firstly, a possible partnership; and secondly, the possible return to him at an increased salary as his assistant?

Mr. NICOLAS: He proposed to give me £200 a year if I stopped for three months or thereabouts and then a partnership. He parted with Mr. Atkinson on splendid terms.

Mr. HEMMING: When you left him what was the position?

Mr. NICOLAS: He agreed I was going back. Witness proceeded to say that on his return a communication was made to him through another doctor that Mr. Atkinson's attitude towards him had entirely changed and that conduct of the kind alleged in the charge was imputed to him. Witness was not conscious of having done anything to warrant this. He wrote to Mr. Atkinson and asked for an explanation. He did not get an answer but only a letter from the Medical Protection Society signed by Dr. Hugh Woods. Witness denied that he stated to Dr. Woods that he was not going back to Catford. He only visited him to try to obtain an explanation of the letter.

The witness had not completed his evidence when the Council adjourned.

The Council continued the consideration of the charge against Mr. John Papa Nicolas, and the examination of that gentleman was continued by Mr. Hemming, his solicitor.

Mr. NICOLAS went on to say that after he received the letter from Dr. Hugh Woods he was anxious to meet the complaint and to know who the complainant was.

Mr. HEMMING: Mr. Atkinson said that he did not ask for the bond before because he was foolish. Can you give any other reason?

Mr. NICOLAS: I cannot give any reason at all.

Mr. HEMMING asked him if all the time he was with Mr. Atkinson he had been loyal towards him and had done his best for his interests?

Mr. NICOLAS: I always did.

Mr. HEMMING: Did you work for him as hard as it was possible for any man to work?

Mr. NICOLAS: Yes. He denied that he had booked a midwifery case for himself after he returned. It was not true that he had told the person in question that he would give her his address when he returned to England. He did not give her a card with the slightest intention of taking her away from Mr. Atkinson.

Mr. HEMMING: Did you ever endeavour to injure Mr. Atkinson's reputation?

Mr. NICOLAS: No, it was the other way round.

Mr. HEMMING: In event of what you admitted taking place as to an assistantship or a partnership, would it have been to your interest to promote his ability and character rather than to disparage him?

Mr. NICOLAS: Yes.

Mr. HEMMING: Have you ever to any patient made a comparison between your own and Mr. Atkinson's methods?

Mr. NICOLAS: Never.

Mr. HEMMING: Have you ever made a comparison between your own and Mr. Atkinson's treatment?

Mr. NICOLAS: No.

Mr. HEMMING: Have you ever made disparaging remarks about Mr. Atkinson's medicine?

Mr. NICOLAS: No.

Mr. HEMMING: I believe you admit fully you have changed Mr. Atkinson's medicine.

Mr. NICOLAS: Yes.

Mr. HEMMING: Did you consult Mr. Atkinson when you changed the medicine?

Mr. NICOLAS: I always put it in the books whenever I changed my own or his. He went on to say that Mr. Atkinson gave him full permission to use his own skill when he went to patients.

When the proceedings were resumed after an adjournment for luncheon,

Mr. NICOLAS'S examination was continued. He went back to Catford in April, 1907, and started practice there because it was a growing place and there was room for doctors. He knew no reason why he should have refrained from going.

Mr. HEMMING: Since you have been at Catford I believe some patients of Mr. Atkinson have come to you.

Mr. NICOLAS: Yes.

Mr. HEMMING: What steps did you take with regard to Mr. Atkinson's patients?

Mr. NICOLAS: I would not accept any patients of Mr. Atkinson unless I was certain that patient had severed his connexion with Mr. Atkinson.

The witness was then cross-examined by Mr. Neilson, who took him step by step through his association with Mr. Atkinson. He went to Mr. Atkinson in the spring of 1906 and the question of signing a bond was not raised then. He denied that such a question was raised until a month before he left. He repeated his assertion that when he left Mr. Atkinson there was an arrangement that after he returned from his voyage abroad he was to return to Mr. Atkinson first as assistant and then as partner.

Mr. Neilson: Do you now tell the Council that there was no price fixed which you were to pay for the privilege of having a share in his practice?

Mr. Nicolas: There was no money named.

Mr. Neilson: You did not think you were going to get the share for nothing.

Mr. Nicolas: Oh, no.

Mr. Neilson: What was arranged?

Mr. Nicolas: It was arranged I was to come back as assistant if I came back from abroad in about two or three months. He admitted no specific month was named. He thought that later on he was to get a share in the practice—he understood about a fifth. He was distinctly under that impression. The practice, he believed, brought about £1500 a year. That meant he would get £300 a year after three months. He thought that it was understood that the terms would be two years' purchase. Those were usual terms.

Hr. Neilson: Was that ever named between Mr. Atkinson and yourself?

Mr. Nicolas: It was understood.

Mr. Neilson: You were wrong then in what you told the Council just now about the terms.

Mr. Nicolas: I remember now what it was. He went on to say that he had read the declarations lodged in support of the case and he had seen many of the declarants with the exception of one, whose statement he characterised as an invention. When he knew what charges Mr. Atkinson was bringing against him he did not write to him. He could not write to a man who had insulted him. He went on to say that one of the witnesses who had appeared had said she had got *5s.* to come to the Council.

Mr. Neilson: Do you suggest that the London and Counties Protection Society had paid a woman *5s.* to come and give false evidence?

Mr. Nicolas: That was what she said.

Mr. Neilson: Do you suggest, standing in the witness-box to give evidence before the Council, that this woman was paid *5s.* to come here and give false evidence by the London and Counties Protection Society?

Mr. Nicolas: Very likely she has from that society or some other society. Whether she gave true or false evidence I do not know.

Mr. Lushington: You suggest that the society has paid her to give false evidence.

Mr. Nicolas: I cannot say positively the society. I withdraw, but she said she was paid *5s.* He would not now suggest that the society had paid her to give false evidence. The cross-examination further dealt with certain detailed allegations.

Further hearing of evidence for the defence was postponed.

The Council adjourned.

WEDNESDAY, JUNE 3RD.

The Council resumed its sittings at its offices to-day, *Dr. Donald MacAlister, the President, being in the chair.*

The Catford Case.

The Council continued hearing evidence in defence of Mr. John Papa Nicolas, who had been summoned before it on a charge of having systematically canvassed in Catford for patients.

Mr. Hemming (solicitor for Mr. Nicolas) said that it would be remembered that on Monday last he handed in a protest against the legal assessor. He had subsequently requested the legal assessor to refer the matter to his own Bar Council. He had had no reply.

The President: I cannot allow you to make that remark.

Mr. Hemming: It is true.

Mr. Henry G. Fraser, packing case maker, Sandhurst-road, Catford, was then called as a witness. He did not know Mr. Atkinson. Mr. Nicolas was his doctor. He had never been canvassed by Mr. Nicolas. He had recommended him on his own motion.

Mr. Neilson: Do you know Dr. Atkinson?

Mr. Fraser: No, Sir.

Mr. Neilson: What did you come all the way from Catford for?

Mr. Fraser: I came on Mr. Nicolas's behalf.

Mr. Arthur Fraser, also of Sandhurst-road, Catford, gave evidence that he had once consulted Mr. Atkinson, but he had gone to Mr. Nicolas. The reason of his change was that Mr. Nicolas was a clever man.

Mr. Lushington (the legal assessor): The Council has had a large class of this kind of evidence—namely, on the point that there are plenty of patients of Mr. Nicolas's who have not been canvassed. Of course, I told you what we thought of that class of evidence before.

Mr. Hemming said that he would call no more evidence. The legal assessor had said that he would advise the Council on certain points. Would that advice be given in the hearing of the accused?

Mr. Lushington said that it would not be so given. On the conclusion of the hearing the Council would begin to deliberate *in camerâ*. If the members of the Council called upon him to advise them *in camerâ* he was there for that purpose.

Mr. Hemming: Will any statement be volunteered to the Council or will it only be in answer to any request? A judge only speaks to the jury in the presence of the accused. I protest against the legal assessor saying anything to the members of this Council unless my client hears it.

Mr. Lushington: I am not here to do as a judge, nor am I in attendance as a judge.

Mr. Hemming: It will happen that there will be something secret after my client leaves this room. He then proceeded to address the Council and to review the case. He called attention to the high testimonials which had been given to the skill and ability of Mr. Nicolas, and the inquiry was the most serious one in which he could be involved unless it was an inquiry involving life and death. Mr. Atkinson admitted that at the time when Mr. Nicolas left his service he thought he was a young man of considerable ability. He afterwards turned round and attacked Mr. Nicolas, but there was nothing, he argued, to warrant Mr. Atkinson's attack on Mr. Nicolas. He had every confidence that he could demonstrate the character of Mr. Nicolas and his courage in meeting this charge, and also Mr. Atkinson's reluctance to come into the open and meet various charges fair and square. If the complaint against Mr. Nicolas was an absolutely honest one what objection could there be to letting him know what that complaint was? When the application was first made for the document there was not the slightest expectation that it would be withheld. The substance of his complaint was that he had been driven to take extreme steps in order to get a copy of the document to which he was entitled. It was not until there was a threat of proceedings against the Council that he succeeded in getting a copy of the document.

Dr. Little (intervening) said he was very unwilling to rise, but he thought Mr. Hemming was not really aware of the case before the Council. They were not called on now to decide whether the modes of procedure of that court were right or wrong. They were called on to consider the conduct of Mr. Nicolas and the learned counsel had not said one word about that up to the present time. The members of the Council had no right to be kept there listening to arguments as to the mode of procedure of the court.

Sir Christopher Nixon protested against the observations of Dr. Little. He thought he was justified in saying that after the large expenditure of time that had been given to this case there should be no attempt made by any member of the Council in any way to restrict the rights of the advocate for the accused practitioner.

Dr. Saundby supported the protest of Dr. Little. Mr. Hemming had been impugning the procedure of the Council. If that procedure was wrong it could be dealt with at another time. No good could possibly come through going over matters which were perfectly well known to the Council.

Mr. Hemming continued his address. He believed if the Council knew his object in making the observations he had done they would be a little more patient with him. He had no wish in any way to irritate members of the Council but rather to conciliate them. It was open to him to show that the procedure of the Council had very considerably impeded his defence in these proceedings. He expected that Mr. Atkinson would go into the witness box after he got a copy of the document but Mr. Atkinson had not gone into the box. It was the original wrongful withholding of the document and the absolute compulsion he was under to get it, that had led to Mr. Atkinson being only partially cross-examined by him. Mr. Hemming then commented at length on Mr. Atkinson's declaration and pointed out a number of variations between the original complaint of Dr. Woods and the charge as ultimately formulated by the solicitor to the Council. That fact alone, he submitted, justified him in strenuously asking for the original complaint. The charge his client had to meet had been enlarged and elaborated and now appeared dressed up in quite a different form. He contended that it was the original complaint his client should have to answer and that it did not lie with the solicitor to make a new charge. It was the solicitor's duty to frame the charge on the material originally placed before the Council and not to introduce anything fresh. He could show that there had been a very serious addition made to the original charge and to that extent he submitted the proceedings were irregular. His client was charged with "infamous conduct in a professional respect." The word "infamous" was one of the strongest they could find in the dictionary. At the very worst, what Mr. Nicolas had been guilty of was nothing more than a boyish indiscretion. If the word "infamous" was to be used in its ordinary sense it could not possibly be applied to such trivial acts as might have been committed by his client. Mr. Hemming went on to review the sworn declarations of the witnesses for the complainants and referred to the remarkable fact that no less than four of these declarations had been disowned by the people who signed them. He contended that the greater part of the evidence put forward by the London and Counties Medical Protection Society was utterly unreliable and ought to be received with contempt by the Council. His client's future was now, forsooth, to be dependent on the evidence in which there was clearly animus. He went on to deal with his cross-examination of Mr. Atkinson, taken in November.

Dr. SAUNDBY: If we are to listen to the reading of the evidence over again it would be taking up the time of the Council most unfairly.

Mr. HEMMING: I am only going to read the part relating to partnership. Mr. Atkinson, he said, admitted it might have been mooted but he had no recollection of it. He submitted that Mr. Atkinson's answers were vacillating on that point. It was inconceivable that Mr. Nicolas would go round and canvass Mr. Atkinson's patients if he was looking forward to be his partner or assistant. If there was a partnership or an assistantship mooted there could be no charge of canvassing before August, 1906. If Mr. Atkinson admitted mooting the question of partnership the charge failed. If Mr. Nicolas had any hope of being Mr. Atkinson's partner he would not have canvassed his patients. It would not have been worth his while. Mr. Nicolas was precise with regard to the mention of a partnership, and he would ask the Council to come to the conclusion that a partnership was mentioned. He contended that Mr. Nicolas in his cross-examination vindicated the consistency of his evidence. He said that Mr. Atkinson had not produced a patient which Mr. Nicolas had canvassed and taken away from him. Mr. Nicolas after he left Mr. Atkinson's employment went away from Catford for eight months. He set up about a third of a mile from a branch surgery of Mr. Atkinson in a district where there were hundreds of new houses springing up. When this charge was taken step by step its hollowness would be seen.

Mr. NEILSON then addressed the Council on behalf of the complainants. He pointed out that the case before the Council was entirely different from the action for libel in the High Court. This case was a charge against Mr. Nicolas for infamous conduct in a professional respect. Two different issues and entirely different matters were involved in the cases. The complaint against Mr. Nicolas was made by the Medical Protection Society as far back as June, 1907. The writ on which the action for libel by Mr. Nicolas was based was not issued until Nov. 15th. A comparison of these two dates exactly showed with what eagerness Mr. Nicolas pursued his redress in the first instance. Now as regarded the charge the burden of it was that Mr. Nicolas had systematically canvassed in Catford for patients by personal visits to patients of Mr. Thomas William Atkinson. It was suggested that that was not infamous conduct in respect of his profession. He would remind them of the definition of infamous conduct in a professional respect. Lord Esher in 1894 laid it down that if it was shown that a medical man in pursuit of his profession had done something with regard to it which would be reasonably regarded as disgraceful or dishonourable by his professional brethren of good repute, then it was open for the General Medical Council to say that he had been guilty of infamous conduct in a professional respect. He submitted that definition for the consideration of the Council in all its aspects and he would say with the greatest confidence that if the charges which were alleged against Mr. Nicolas in this case and supported by evidence were true then no more complete example of infamous conduct in a professional respect could be found applicable to the medical profession, of which he was a member. If the Council found what he submitted was true he hoped that they would have no difficulty in finding the accused practitioner guilty of infamous conduct in a professional respect. He went on to review the incidents of the case. He asserted that when Mr. Nicolas was asked to sign the bond he refused and said he would rather go. He repudiated the idea that there was a suggestion for a partnership. The whole thing, he submitted, was an invention from start to finish. He suggested that if Mr. Nicolas asked Mr. Atkinson if there was a chance of partnership Mr. Atkinson replied not for several years. That was consistent with a statement made by Mr. Hemming. Why should Mr. Atkinson take this man who had given notice as a partner? Mr. Nicolas had no money. The whole position was entirely inconsistent in what Mr. Nicolas said now and what was said in November. He went on to say that when Mr. Nicolas was away from Catford from September, 1906, to April, 1907, there were rumours that he was coming back to practise in opposition to Mr. Atkinson. He would ask the Council to disbelieve some of the allegations made in regard to events about this time by Mr. Nicolas. It was Mr. Hemming's case that all these people who had been called for the complainants had conspired to raise a grossly dishonest case for the purposes of misleading the General Medical Council. It was that or nothing. He suggested that his (Mr. Neilson's) witnesses spoke the truth, that they came to tell the truth, and in their cross-examination their veracity was absolutely untouched. He submitted that Mr. Nicolas came back to Catford in pursuance of a scheme he had previously formed and in order to show Mr. Atkinson that he was going to do what he liked in the matter. The only explanation of the circumstances which was possible and true was that when Mr. Nicolas found that he did not get a bond, when he found he had not signed a bond, when he found it was necessary that he should sign a bond, he thereupon gave notice to go. He made the most of his time between the notice and the time he went. He had plans laid about a house before he went. He pursued these plans after he came back. He came back and canvassed the patients of Mr. Atkinson whom he could remember. Mr. Nicolas denied that. The question was, Which side should the Council believe? He submitted that his witnesses had spoken the truth and he asked the Council to find that Mr. Nicolas had canvassed the patients of Mr. Atkinson and that the Council should deal with him accordingly.

Mr. LUSHINGTON made a short statement in which he said that the Council had all along been guided by the advice of their legal advisers on points of procedure. He pointed out that one witness had made two declarations, one on one side, the other on the other. The solicitor and he had held it to be their duty that he should ask leave in such a case that they might look at both declarations to see whether they should advise the Council to send them to the Public Prosecutor.

This closed the hearing of the case.

After deliberation *in camerâ*,

The PRESIDENT said: Mr. John Papa Nicolas, I have to announce to you the decision of the Council. The Council have judged you to have been guilty of infamous conduct in a professional respect and have directed the Registrar to erase from the Register the name of John Papa Nicolas.

Mr. HEMMING asked that the erasure might be postponed for a month in order that he might apply for a writ of *certiorari*.

The PRESIDENT: You can make your application to the office in the usual way and we shall answer it.

The Public Health Committee.

On the motion of Dr. LINDSAY STEVEN the report of the Public Health Committee was received. It was in the following terms: An application has been received from the University of Sheffield for the recognition of its Diploma in Public Health. The committee has carefully considered these regulations and finds that they are drawn on similar lines to those of the Universities of Liverpool and Leeds. The committee observe, however, that the regulations as they stand are not as regards Rule 4 completely in accord with those of the Council. Subject to modification in the above sense the committee recommend the Council to recognise for registration the Diploma in Public Health of the University of Sheffield.

Dr. **LINDSAY STEVEN** moved that the Council should recognise the Diploma in Public Health of the University of Sheffield conditional on the regulations being brought into accord with Rule 4 of the Council and that the President should be authorised to give effect to this resolution on being satisfied that the condition had been fulfilled. If the University of Sheffield would agree to make it clear that they demanded an examination and education in methods of hospital administration then he thought they might leave it in the hands of the President to grant the diploma full recognition.

Dr. **NORMAN WALKER** seconded.

The motion was agreed to.

The Reading of the Minutes.

Mr. **MORRIS** moved to discontinue the practice of having the minutes read over each morning by the Registrar immediately after the Council assembled. Nearly £1 was disbursed by the Council for each minute which it sat. The reading of the minutes on an average took a quarter of an hour. On working that out he found that it cost the Council from £11 10*s*. to £13 10*s* every time the minutes were read over to them. This session they had spent £108 for listening to the minutes being read. He thought that they should take the minutes as read, especially as they were circulated to members in printed form every morning.

Mr. **TOMES** seconded the motion.

Dr. **MCVAIL** suggested that the subject should be referred to the Executive Committee to consider.

After a short discussion a suggestion on the lines of that made by Dr. McVail was agreed to.

The Administration of Anæsthetics.

The Council then took up the consideration of the report by the Education Committee in regard to a communication from the Privy Council on the subject of the administration of anæsthetics. Its terms were: The following communication has been referred to the committee by the President:—

The Clerk of the Council, Privy Council Office,
No. 100,278. London, S.W., March 27th, 1908.

Sir,—Referring to a resolution (copy inclosed) adopted by the members of the Medico-Legal Society and others at a meeting held on the 24th instant, urging legislation with a view to making the administration of anæsthetics illegal except by duly registered medical practitioners, I am directed by the Lord President of the Council to state that his lordship will be glad to be favoured with any observations the General Medical Council may have to offer thereon.

I am Sir, your obedient servant,
The Registrar, General Medical Council. A. W. FITZROY.

[COPY.]

MEDICO-LEGAL SOCIETY.
MARCH 24TH, 1908.

At the close of the meeting Dr. Frederic Hewitt will propose, and Mr. R. Henslowe Wellington will second, the following motion:—

"That the two following resolutions be forwarded, in the name of the Medico-Legal Society, to the Privy Council and to the General Medical Council respectively:—

'That as the administration of any drug or drugs, with the object of producing generalised insensibility to pain or actual unconsciousness for any medical or surgical purpose, or during child-birth, cannot be safely undertaken without medical knowledge and skill, your petitioners humbly pray that legislation be granted whereby the administration of any drug or drugs with either of the aforesaid objects by any person other than a duly registered medical practitioner or someone acting immediately under his supervision, direction, and instruction, be made a penal offence.

That in view of the importance of the administration of anæsthetics, this society is of opinion that it is highly desirable in the public interest that every member of the medical profession, before he is registered, shall have received instruction in the administration of anæsthetics. It therefore earnestly begs the General Medical Council to consider whether they can see their way to include a course of instruction in anæsthetics amongst their "Requirements in regard to Professional Education."'

STANLEY B. ATKINSON, } Hon. Secs."
DIGBY COTES-PREEDY, }

The committee recommend that the reply of the Council be in the following terms:—

I. The General Medical Council has consistently endeavoured to safeguard the interests of the public in matters relating to the practice of medicine. They will, therefore, willingly support any measure which has as its object to render illegal the practice, save by duly qualified and registered practitioners, of any department of medicine and surgery, including the branch of practice to which special reference is made in the communication from the Privy Council—viz., the administration of anæsthetics.

II. The Council has within the last year issued a "recommendation" to the Licensing Bodies that a course of study in the administration of anæsthetics should be included in the curriculum; and they have reason to believe that the "recommendation" has been already given effect to by many of the bodies.

Dr. **MACKAY** moved the adoption of the report and that the reply to the Privy Council should be in the terms which it recommended.

Dr. **LINDSAY STEVEN** seconded. He said that the subject the report referred to had been brought prominently before the body which he represented. In Glasgow the Procurator-Fiscal had been taking an active interest in the administration of chloroform, particularly in connexion with certain deaths. He had sent an inquiry to the Faculty of Physicians and Surgeons whether they could make any regulation whereby it could be insured that two medical men should be present where chloroform was being administered.

The motion was agreed to.

The Registrar, Mr. H. E. Allen, was reappointed, and on the motion of Dr. **MACKAY** a vote of thanks was awarded to the President for his service in the chair.

The session of the Council then came to an end and it adjourned until November.

It may be explained that owing to the length of the session and the very long time occupied in the consideration of the Catford case several items which were put down on the programme for discussion were postponed until the next session of the Council. The decision in the Catford case was not given till 6 30 P.M. and the discussion on the various motions was abbreviated so as to obviate a sitting on the following day.

ASYLUM REPORTS.

Kingseat Asylum, Aberdeen.—There were under treatment at this asylum during 1907 261 males and 237 females, being a total of 498 patients. The discharges during the year numbered 48. 16 men and 18 women were discharged recovered, the percentage of recoveries calculated on the admissions being 39·5. Of the recoveries 10 had been resident for at least three months, 11 between three and six months, seven between six and nine months, one between nine months and a year, four between one and two years, and one under three years. The deaths numbered 34—17 men and 17 women. These figures give a death-rate of 8·2 per cent. on the average number of patients resident and of 6 8 per cent. on the total number under treatment. We note that the medical superintendent, Dr. H. de M. Alexander, reports that the privilege of parole has been greatly extended and with the most happy results. Dr. Alexander writes: "It has been frequently observed that a few patients who are irritable, discontented, and lazy when confined become more contented and begin to work on their own initiative on being allowed greater liberty."

Glasgow Royal Asylum.—At this asylum the total number under care for 1907 was 563. The discharges during the year numbered 103. 27 men and 26 women left as recovered, a percentage of 36·5 on the total admissions. 30 recovered after less than three months' treatment, 18 after less than 12 months, and five after treatment lasting from one to four years. The deaths were 29 in number, giving a percentage of 6·8 on the average number resident. Dr. L. R. Oswald, the physician-superintendent, points with satisfaction to the fact that during the last three years 105 persons have sought treatment in his hospital of their own free-will and argues therefrom that the public is slowly realising that the best hope for the mental sufferer lies in an early resort to such special treatment as can only be got in institutions properly equipped and adapted. Dr. Oswald further notes that the recovery-rate of voluntary patients is higher than that of those who are certified, that the duration of treatment is shorter, and that only in a small number of cases is it necessary to resort to certification.

Barnwood House.—The total number of certified patients under treatment during 1907 was 182. Ten patients were discharged recovered—that is, 29·4 per cent. on the admissions. The number of deaths was ten, giving a death-rate of 6 71 per cent. on the daily average number resident.

St. Andrew's Hospital, Northampton.—At this hospital the total number of patients under treatment during 1907 was 496 34 patients were discharged recovered, being a percentage of 40·47 on the admissions. 13 deaths occurred, being a percentage on the average number resident of 3·17. The extensive alterations and additions which have been going on at this hospital are now completed. A resident medical officer has been appointed to look after the patients resident at the seaside home at Bryn-y-Neuadd.

THE LANCET.

LONDON: SATURDAY, JUNE 13, 1908.

The Medical Man and the Coroner.

IT may be remembered by our readers that in the years 1903 and 1904 the heading which we have printed above this article occurred very frequently in our columns, generally with the addition of the word "Pathologist." During those years we were engaged often in referring to the extraordinary position which was taken up by Mr. TROUTBECK, the coroner for Westminster and South-West London, in connexion with the giving of medical evidence in inquests which he held. Mr. TROUTBECK, it appeared, had assumed office on the understanding with the London County Council that he should adopt a policy recommended by the control committee of that body which obliged him to intrust the post-mortem examinations in all cases "of a special nature" to a specially skilled pathologist. So liberally did he interpret his mandate that —we quote from a letter by Mr. DONALD SHEARER in the *Times* of June 9th—"between May, 1903, and February, 1905, Mr. TROUTBECK found it necessary to call in a special pathologist, Dr. FREYBERGER, 816 times in place of the local or hospital medical attendant. During the same period the other seven coroners in London had between them 46 cases requiring special pathological knowledge. On most, if not all, of these 816 occasions public money was wasted; in not a few an erroneous verdict was arrived at for want of accurate clinical information." The justice of these remarks will be apparent to any fair-minded reader of many cases which we reported in 1903, cases in which the evidence of the medical practitioner who had attended the deceased would have had obvious value in correcting or corroborating post-mortem findings by clinical observations. In 1904 the legality of Mr. TROUTBECK'S conduct was challenged, and many instances of the omission of highly relevant evidence were reported to the LORD CHANCELLOR by a joint deputation of the British Medical Association and other societies which sought to call attention to the dangers of the new procedure. It will be remembered that Lord HALSBURY'S reply was a *non possumus*, for in a letter dated July 29th, 1904, the societies which had approached him were informed "though his lordship's present impression is not in favour of the coroner's practice, his lordship does not as yet see that there is such a case as would found the exercise of the only jurisdiction which he possesses—namely, to remove a coroner for misconduct in his office." The snub to Mr. TROUTBECK had, be believe, no effect on him.

We should hardly have present occasion to re-tell this story were it not that Mr. TROUTBECK has seen fit to give a further exhibition of his attitude towards the practice of medicine. It is true that in the former controversy he was wont to protest that he was guided by strictly impersonal motives, but his thinly veiled suggestions that professional opposition to his innovation was the simple result of fee-hunger and his free attribution of "impertinence" to medical men in disagreement with him caused doubts to arise as to his strictly judicial frame of mind. He may, of course, in his latest anti-medical dictum be again displaying strict impersonality, but his behaviour, while it can bring serious grief into suffering families, appears on the face of it to be instigated by a desire to show that the fee-hungry medical profession is also actuated by murderous instincts. The occasion for Mr. TROUTBECK'S activity against the medical profession arose as follows. It appeared by the proceedings at an inquest that Sir VICTOR HORSLEY had operated on a patient at the Bolingbroke Hospital, from whom he removed a cerebellar tumour. Three days after the operation the patient died, the cause of death, for which a certificate had been duly given to the registrar, being heart failure due to pressure which had been previously exerted on the nervous system by the tumour. An inquest was held by Mr. TROUTBECK, before whom, in the course of giving his evidence, Sir VICTOR HORSLEY protested against the holding of an inquest in so plain a case. The jury returned a verdict of "Accidental death," which the coroner suggested to them at the close of a homily which was virtually an attack upon the practice of surgery. Mr. TROUTBECK'S views on the progress of medicine ran something as follows. He said that operations were much more frequent than they used to be and that clearly they were to some extent the cause of the deaths that resulted; they could therefore not possibly be called natural deaths and came within the Coroners Act of 1887 which made inquests imperative in such cases; and he attempted, or is reported to have attempted, to clinch this argument by saying that such was the opinion of all coroners. It is hard to see how this statement can be reconciled with the following passage from the report of the Coroners Society for 1902–03: "In cases where a patient has recovered from the effects of the anæsthesia, and the death was due to a necessary operation or the disease for which the operation was performed, an inquest is not required; provided always that there is no allegation of neglect, serious rumours, or presumed want of skill on the part of the operator, or that the friends of the deceased do not request an inquest for their satisfaction." In this light any appeal by Mr. TROUTBECK to his colleagues must appear unfortunate; if he has quoted them as being of his opinion he is not a very accurate person. We can imagine a medical coroner, with some show of logicality, sitting to inquire into such an event as a death after a surgical operation, if scientific grounds appeared to warrant the inquiry, but how anyone of Mr. TROUTBECK'S attainments, which may be enormous in the legal direction, could possibly guide a body of men like a coroner's jury to any sort of verdict upon the circumstances of a surgical operation passes imagination.

Mr. TROUTBECK'S departure shows him once again to be ignorant of the spirit of the medical profession. Is he correct in his legal interpretation of his duties? The third section of the Coroners Act of 1887 provides that where a coroner is informed that the dead body of a person is lying within his jurisdiction, and that there is reasonable cause to suspect that such person has died a violent and unnatural death or has died a sudden death, of which the cause is unknown, or "in such place or under such circumstances as to require an inquest in pursuance of any Act," the coroner shall summon a jury. He would be a zealot, indeed, who construed this language to mean that an inquest must be held in every case where a patient has not proved amenable to surgical treatment. If Mr. TROUTBECK bases his contention on the fact that death in such a case is "unnatural" he would have to go further and say that the cause of every death taking place after medical treatment of any kind should be investigated by a coroners' jury. It is further implied in the Registration Act of 1874 that a death from disease under treatment *secundum artem* is not unnatural, and without such a safeguard medical practice would be impossible. The more we reflect upon Mr. TROUTBECK'S latest move the more he seems to have been instigated by a simple desire to wound the medical profession which cannot be got to regard him as anything but mischievous. But the public will suffer if Mr. TROUTBECK has his way much more than the medical profession. Mr. TROUTBECK will not be able to persuade juries that medical men operate the love of giving pain and from lust of gold, regardless of the true needs of the patients; and the distress caused by the publicity of unnecessary inquests to many families in the first grief of a bereavement will be extreme.

◆

The Value of the Surrey Isolation Hospitals.

DR. EDWARD C. SEATON, the county medical officer of health of Surrey, has recently issued an interesting and instructive report with reference to the effect of the operation of isolation hospitals and compulsory notification in that county upon the behaviour of scarlet fever, and in his investigations he has been ably seconded by Dr. JOHN WILLIAMSON who has conducted some original and valuable researches upon the subject. As a frontispiece to the report is a chart showing the death-rate from scarlet fever per 1,000,000 of the population in England and Wales from 1856–1906, and this chart brings out the now well-known fact that a marked decline in the death-rate of the disease had commenced prior to the general provision of isolation hospitals and long antecedent to the introduction of compulsory notification. This circumstance is obviously one of first-rate importance in a consideration of the influence of isolation but it is nevertheless easily possible to over-estimate its value. Question at once arises as to what this decline in the death-rate really means. Does it imply diminished prevalence of the disease, or may it be that while the disease itself is becoming far less virulent its actual prevalence is as great as, or even greater than, before? This question is very difficult, if not impossible, to answer, inasmuch as antecedent to notification we had practically no data as to prevalence, and even with notification we must be careful in generalising. Increase or decrease in the number of notifications may really mean nothing more than a sort of systole and diastole of the type of the disease—at one period easily recognisable, at another only so with difficulty. Again, our medical practitioners may be becoming more expert in the recognition of the disease than formerly.

It must, nevertheless, be said that the evidence in favour of a diminished fatality-rate of the disease during recent times is very strong—indeed, practically conclusive, and the question to be asked is, How far is such decrease to be attributed to the operation of notification and isolation? Before an answer could be found to this question it would be desirable to investigate the behaviour of scarlet fever in countries where there are practically no isolation hospitals, but as Dr. SEATON has not gone into this aspect of the question we shall not do so ourselves; and it has certainly to be admitted that in the present unsatisfactory condition of statistical returns in almost every other country but our own journeys into international figures are perilous undertakings likely to lead to inferences of a far-reaching but not improbably mischievous and misleading character. In so far as Surrey is concerned, Dr. SEATON concludes that isolation and notification have had an influence in the reduction both of the death-rate and the fatality-rate of scarlet fever, but he does not find it possible to detect how far, if at all, the attack-rate has been influenced—i.e., it cannot be shown, he thinks, that the preventive measures taken have materially affected the *notification* case-rate. He finds, in fact, that there is "no very obvious correspondence between the hospital isolation and the prevalence of the disease." The fact that there is "somewhat *less* scarlet fever in a district *with* isolation accommodation than in the same district without" is, of course, as Dr. SEATON recognises, not very convincing as to the value of isolation hospitals, and it is at this stage that Dr. WILLIAMSON'S *investigations may be usefully introduced.*

He has at considerable pains investigated the history of all notified cases in the Epsom and Dorking combined districts from 1891–1905 and his results are presented in the form of charts, "hospital" and "home" treated cases being depicted separately and, by way of eliminating the possibly disturbing factors of good class houses, he has dealt with cottage cases only—i.e., cases where the opportunities for proper isolation were clearly remote. The general conclusions brought out by these charts are those which we have on many occasions predicted in these columns—i.e., that the major damage as regards the *infection of other persons is brought about before the first case has been recognised, notified, or sent to hospital,* and that consequently the influence of isolation hospitals is less than had at one time been anticipated. Dr. WILLIAMSON'S "hospital" charts indicate that a very high percentage of secondary cases were infected before the removal of the first patient; they show, indeed, that somewhere about two-thirds of the secondary cases are thus to be accounted for. The charts, however, bring out the instructive and consoling fact that the advantage as regards the avoidance of secondary cases is always on the side of the hospital until after the seventh week from the occurrence of the primary attack when the so-called "return" cases begin to appear and, seemingly, influence the "hospital" chart to a materially greater degree than the "home" chart. As Dr. WILLIAMSON concludes, "*it is plain, therefore, from* the above charts and figures, that an earlier discovery or recognition of cases is necessary to make hospital isolation fairly effective."

There is no doubt, as we have for years past urged, that it is the *unrecognised* case which governs the situation both as regards scarlet fever and many other diseases, and the work before us is not that of sitting with arms folded but of endeavouring to discover the unrecognised case. There can, we think, be no serious question in the minds of the vast majority of medical officers of health alive to their responsibilities that properly administered isolation hospitals have a very distinct value in our administrative machinery and that the public will continue to demand their provision. It is for this reason that we regret to see certain medical officers of health rather discouraging the erection of such hospitals since there are so many local authorities who are only too anxious to catch at any straw with the view of justifying their inaction. Numerous instances of this have come beneath our notice. It would be especially regrettable at the present time, when the medical inspection of school children is actually in the making, were we to discourage the erection of isolation hospitals. The steady progress of this inspection movement cannot fail to bring to notice very many unrecognised cases of infectious disease which hitherto have escaped notice, and the interest which the teachers will gradually acquire in this inspection will prove eventually to be a powerful factor in the earlier recognition of communicable diseases. Much of the future attitude of local authorities with reference to the provision or non-provision of isolation hospitals depends, we imagine, materially upon that of Dr. ARTHUR NEWSHOLME, the recently appointed medical officer of the Local Government Board, and having regard to the growing scepticism of local authorities as to the value of isolation hospitals, it might serve to steady public opinion were some official pronouncement from Whitehall to be forthcoming.

◆

Tics and their Treatment.

THE term "tic" has long been employed to denote certain habitual and meaningless gestures. Great confusion has, however, existed in regard to the group of conditions to which it has been applied. Even the etymology of the word is somewhat obscure and it has been suggested that it was originally onomatopœic and that it conveyed the idea of repetition. It has long been employed in France and so long ago as 1665 JEAN JOURDIN described the *tique* of horses. It is to the French physicians that we are especially indebted for the definite separation of the true tics from conditions which resemble them, notably to TROUSSEAU, whose description is characteristically clear and accurate, and to CHARCOT, who first established the significance of the psychical factor in tic. GILLES DE LA TOURETTE advanced our knowledge by separating the form to which his name is usually attached, while BRISSAUD and his pupils have further studied the conditions and devised special methods of treatment. Recently M. HENRY MEIGE and M. E. FEINDEL have published a monograph on the Tics, which has been translated into English by Dr. S. A. K. WILSON.[1] This book is a most suggestive contribution to the study of the disease and is well worthy of our readers' consideration. After a detailed analysis of the clinical features of the various tics the authors define the condition as follows: "A tic is a coördinated purposive act, provoked in the first instance by some external cause or by an idea; repetition leads to its becoming habitual and finally to its involuntary reproduction without cause and for no purpose, at the same time as its form, intensity, and frequency are exaggerated; it thus assumes the characters of a convulsive movement, inopportune and excessive; its execution is often preceded by an irresistible impulse, its suppression associated with malaise. The effect of distraction or of volitional effort is to diminish its activity; in sleep it disappears. It occurs in predisposed individuals who usually show other indications of mental instability." Tic is thus to be regarded as a psycho-motor affection, and in tracing its evolution the authors show that the cortex is involved. The original movement may have been voluntarily executed in response to some irritation but in the subject with a tendency to tic the movement is repeated even after the source of irritation has ceased and soon the reiterated gesture becomes habitual and automatic. An interesting chapter deals with the mental state of the subjects of tic. Although they may be, and often are, of high intelligence and fertile in imagination, they usually present on careful investigation definite evidence of mental instability. The most constant feature appears to be one of "mental infantilism"—evidenced chiefly by retarded or arrested development of the will, so that the *tiqueur* cannot exert his will sufficiently to check his tic permanently. The *tiqueur* is also often irresolute, lacking in perseverance, and is subject to vagary and caprice. Tics are also not infrequently associated with obsessions and with various phobias, such as agoraphobia and claustrophobia, indeed some obsessions occurring in the subjects of the tic have been described as "psychical tics" or "tics of idea," terms which M. MEIGE and M. FEINDEL most strongly deprecate the use of, since they insist on the dual nature of tic, one element being mental, the other motor, and the two being inseparable; in other words, they maintain that a mental condition which does not eventuate in some motor reaction is not a tic. In regard to the etiology of tics, heredity is shown to be of great influence, though in regard to direct heredity the factor of imitation is difficult to separate, but dissimilar heredity, both neuropathic and psychopathic, is also very frequent. The environment is a matter of great importance, especially where children are concerned, the parents of *tiqueurs* being often inclined to over-indulge and to "spoil" them. The pathological anatomy of tic is still to seek; hitherto no lesion has been discovered in such cases to which the symptoms can be referred and although cases are on record in which lesions have been described M. MEIGE and M. FEINDEL are of opinion that in all of them the diagnosis has probably been an erroneous one, conditions of spasm from irritation being regarded as tic.

The study of the motor reaction of tics shows that they may be clonic or tonic in character. The various tics are described by M. MEIGE and M. FEINDEL according to the regions which they affect—viz., facial tics, auditory tics, tics of the eyes, including nictitation and vision tics; sniffing tics, sucking tics, tics of the chin, of the tongue, sometimes called licking tics; tics of the jaws, biting and masticatory; tics of the neck, of the trunk, of the arm and shoulder; and tics of the lower extremities, including walking and leaping tics. As examples of tonic tics mental trismus and mental torticollis are instanced. Under the heading of tics of speech, echolalia and coprolalia are described, since they are not infrequently to be observed in the subjects of tic, although the authors do not regard them as tics but simply as associated defects. Gilles de la Tourette's disease is described as a separate form in which the course is regularly progressive and one which is often associated with echolalia and coprolalia. Another form is described as the variable chorea of Brissaud. A chapter is devoted to the antagonistic gestures and stratagems to which the subjects of tic resort in misdirected ingenious attempts to overcome their special tics. In regard to diagnosis, the distinction of tics from stereotyped acts, from spasms, from chorea, myoclonus, athetosis, tremors, and professional cramps is discussed in detail. It is especially in regard to spasms, such as facial spasm and spasmodic torticollis, that difficulty may occur, and illustrative cases are given to show the methods to be adopted. In regard to prognosis, we are told that this depends solely on the mental state of the patient. "He who can will can effect a cure," say the authors, but they also admit that the tendency to tic remains and that whereas tics of childhood are curable a permanent cure is less frequent in the tics of adult life. The treatment of these conditions is given in considerable detail and comprises, in addition to medicinal and certain physical forms of treatment, such as massage and electrical methods, the re-education system introduced by Professor BRISSAUD, which is briefly epitomised by the authors as "a combination of immobilisation of movements with movements of immobilisation." The patient is directed to perform certain appropriate exercises, some being directed towards teaching him how to preserve immobility, while the object of others is to replace an incorrect movement by a normal one. The exercises have in general to be performed in front of a mirror. Examples are given in illustration of the methods of treating various special tics. The book is a model of what a monograph on a special subject should be, for it is clearly and critically written and it is suggestive in character as well as instructive. Dr. WILSON is to be congratulated on the excellence of his translation and on rendering so useful a work available in English form.

---

[1] "Tics and their Treatment," by Henry Meige and E. Feindel. With a preface by Professor Brissaud. Translated and edited with a critical appendix by S. A. K. Wilson, M.A., M.B., B.Sc.Edin. London: Sidney Appleton. 1907. Pp. 386. Price 9s. net.

At a recent meeting of the Neurological Section of the Royal Society of Medicine[2] a discussion on "Tics" was opened by Dr. HENRY HEAD who paid a well-deserved tribute to the part played by French observers in developing our knowledge of this subject. He also laid stress upon the mental factor in the development of tics and stated that although the *tiqueurs* may be above the average in ability there is always something that betrays their want of balance. Dr. E. FARQUHAR BUZZARD pointed out an exception to the general rule that a tic originates in a voluntary movement in that form which occasionally results after a severe attack of chorea. Dr. L. G. GUTHRIE emphasised the importance of distinguishing between tics and spasms, the latter being merely motor reactions to local irritation somewhere in a spinal or bulbo-spinal arc, whereas the tic is a psycho-motor reaction. He also deprecated the use of the term "habit spasm" as a synonym for the tics, since they are certainly not spasms nor are they true habits. The subject is one which is deserving of notice, since the condition is frequently regarded as irremediable, whereas by careful treatment marked amelioration and in some cases actual cure can be effected.

Annotations.

"Ne quid nimis."

THE DANGERS OF MOTOR OMNIBUSES.

THE recent attack made upon several motor omnibuses in Mile End-road after one of their number had run over a child showed that a very strong popular feeling exists against these vehicles, caused by the reckless way in which too often they are driven. As they are maintained largely for the purpose of what may be called "popular" traffic this feeling is worthy of note. The Stepney borough council has, we observe, been considering a resolution to be laid before the Home Secretary and the Commissioner of Police in favour of reducing the maximum speed of all motor and other vehicles within the County of London to ten miles an hour. This would be a regulation which would render London streets safer and less noisy, but if it were to be applied universally it would be extremely difficult to enforce owing to the number of private carriages the owners of which would be found to infringe it, particularly in quiet streets. Motor omnibuses, as a general rule, are driven with far more care and skill than was the case when they were first introduced. We cannot, however, judge them as a whole from what we see of their movements in the West-end and by day. It is at night, and particularly in places where a public frequents the streets whose protests are not likely to reach the ears of those in authority, that they will be found to exceed the proposed limit of ten miles per hour considerably and to take risks which they ought to avoid. The police in regulating them in this respect might also note the manner in which they are allowed to be overcrowded in the evenings when their passengers are going home from their day's work. These, no doubt, prefer to travel rapidly, but that is no reason why people who have secured seats in a motor omnibus should have their safety endangered and their scanty supply of air obstructed by "strap-hangers," while horsed omnibuses proceed in the same direction half empty. We note that the committee of the Stepney borough council responsible for the recommendation to restrict speed had before them figures showing that in 1907 there were 16,010 accidents caused by horseless vehicles on the roads, of which 4723 were due to motor omnibuses. Whether these figures are those of London only or of a wider area we are not aware, but the question in any case is of some gravity.

AN EARLY TEMPERANCE TRACT.

IT is open to the social historian to speculate how far the so-called "crying evils" of the day are an affair of journalistic and literary tradition rather than of actual induction from statistics. It is assumed by many excellent people that England is rapidly degenerating owing to habits of intemperance, to the growth of gambling and immorality, to the love of pleasure, and to the pursuit of gain, but these censors of their time are not students of history and the evolution of manners. Rather they are highly suggestionised readers of cheap newspapers and followers of particular prophets whose tradition in both cases may be said to date back to the palmy days of

---

Puritanism. As long ago as 1628 William Prynne published the first rabid temperance tract under the title, "Healthes Sicknesse, or a Compendious and briefe Discourse, proving the Drinking, and Pledging of Healthes, to be Sinfull, and utterly Unlawfull unto Christians; by Arguments, Scriptures, Fathers, Moderne Divines, Christian Authors, Historians, Councels; Imperiall Lawes and Constitutions; and by the voice and verdict of prophane and Heathen Writers." It is a question whether Prynne did not set going for all time the bogey of national intemperance. He seems to have been among the first to discover that drunkenness was *par excellence* the national vice, but he believed this failing to be of recent introduction into England. According to him the custom of drinking healths came into England from Europe—from Germany, Poland, and Scandinavia. He condemned the custom as a relic of primitive devil-worship and rightly maintained that, owing to the principle of "no heel-taps," it involved an excess of drinking which was injurious to health. He fails to recognise that Anglo-Saxons have always been robust drinkers and he attributes all the intemperance of his age—which was very nearly the period of Falstaff—to the habit of "healthing." His learning is so vast and his citations from the Greek and Roman writers are so copious that we are inclined to believe him to have been rather a student of books than an observer of facts. The England of 1628 drank wine and ale, and strong waters were only introduced into common use by his own kindred, the "saints" of the time of the Civil War. It was not till quite a century after Prynne's time that gin began to be the ruin of the eighteenth century working-classes. When Prynne penned his terrific tract England was probably neither more drunken nor less sober than at any period since the days of Hengist and Horsa.

MILK EPIDEMIC IN CHRISTIANIA.

Dr. Sömme of Mesnalien Sanatorium, in the *Norsk Magazin for Laegevidenskab* describes an extraordinary milk epidemic in Christiania which broke out during the first fortnight in March. The attack in almost every case began with a sore-throat. It was speedily traced to the milk-supply of one dairy and thence to a cow with a diseased udder. The cow was slaughtered and a bacteriological examination of the abscess found in the udder led to the isolation of streptococci in every way identical with the streptococci obtained from patients suffering from the epidemic. The streptococci showed the following characteristics: moderately long chains, each link being fairly long and divided longitudinally. They stained with Gram's method. Stained specimens suggested the presence of a capsule. On a serum culture the growth showed a thin moist film, almost watery, only a little adhering to a thread drawn over it. It did not grow on ordinary agar—on agar made alkaline the growth was slight. Ready growth took place in ordinary bouillon, ascitic and serum bouillon, and on plates of serum bouillon (Löffler's) with dextrose or lævulose added. Mice died in from 12 to 24 hours after intraperitoneal injections of minute quantities of the culture and cultures were easily obtained from the blood. It was found to be much less virulent for rabbits. The number of cases of the epidemic notified was 548, but as notification was voluntary it is probable that the number was considerably higher. An interesting feature of the epidemic has been the high proportion of adults affected, the ratio of adults to children being about 3 to 1. The clinical picture of the illness was as follows. High temperature, 40° C. or more, with sore-throat. The surface of the tonsils, pharynx, and downwards towards the larynx was of a glistening red; in other cases the redness was confined to punctate areas, and in yet others there was a diphtheria-like membrane which was easily removed. In the majority of cases the appearance of the throat was scarlatinal rather than diphtheritic. Swelling of the glands extended from the angle of the jaw downwards along the sterno-mastoid to the clavicle. In some cases the swelling was slight but the glands were excessively painful on pressure, and this condition sometimes lasted for a long time. Often the temperature fell by crisis after three days, then a relapse would occur followed by another crisis, febrile and non-febrile phases alternating during a period of many weeks. Complications, chiefly of a pyæmic character, were numerous; thus angina phlegmonosa occurred frequently; in one case a number of abscesses occurred on both sides of the throat accompanied by copious hæmorrhages from the nose and mouth. The odour of the pus was very offensive. One patient was almost choked by a purulent uvula of the size of a man's thumb. Further complications were rhino-pharyngitis, laryngitis, otitis media, ulcers of the tonsils and palate, empyema of the antrum of Highmore, infection of the accessory cavities of the nose, glossitis of such virulence that the swollen organ protruded from the mouth, erysipelas, in one case dacyro-cystitis, stomatitis, œsophagitis with dysphagia, and albuminuria. Other complications were pyarthrosis, acute rheumatic fever, synovitis, bronchitis, empyema, pleurisy, pericarditis, hæmorrhagic nephritis, phlegmasia alba dolens cruris, paresis of the left hamstring muscles, and erythema of both legs two weeks after infection. Gastro-enteritis and diarrhœa were apparently not common. Of the cases ending fatally the following may be cited. Case 1. A male, aged 81 years; heart failure occurred on the fifth day. Case 2. A female, aged 74 years; fever, vomiting, pain, and effusion in the left knee-joint and right carpus. Death took place a fortnight after infection. Characteristic streptococci were found in pus from the knee-joint. There were parenchymatous degeneration of the liver and kidneys and fatty infiltration and dilatation of the heart. Case 3. A male child, aged 16 months; diarrhœa, vomiting, fever lasting only from four to five days, and empyema. Death ensued on the eleventh day. Case 4. A female, aged 47 years; general glandular swelling. The patient was convalescent after the third week, then ensued sudden onset of pain in the muscles, principally those of the lower extremities, and pain in both knees and wrists, also in the temporo-maxillary joint; the temperature gradually rose to 43° C., accompanied by dyspnœa and œdema of the lungs. Death occurred a week after the onset of the relapse. Post mortem there were ecchymoses on the surface of the heart but none on the lungs. The spleen was soft and swollen, with well-defined markings. Serous exudate was present in the knee-joints. Case 5. A female child, aged four months (case of fatal secondary infection). An inflamed nævus had been treated with lanolin also used for an otitis media in an older child suffering from the milk epidemic. There was meningitis and lumbar puncture showed the typical streptococci. The child was breast-fed. A somewhat similar epidemic involving 15 patients is described by Dr. C. Grey-Edwards and Mr. W. D. Severn in THE LANCET of June 12th, 1897, p. 1605.

"CANARY FEVER."

IN a recent number of the *Annals of Tropical Medicine and Parasitology* Dr. C. E. Walker contributes an interesting study of a troublesome illness to which visitors to the Canary Islands are particularly susceptible and which is generally known as "Canary fever." The result of Dr. Walker's inquiry has been to show that this is simply due to a bacterial infection of food, such as might occur in any country, and he has been unable to find any evidence as to a specific infective agent in the disease. The symptoms are those of a gastro-enteritis with very severe griping pains, and sometimes the passage of blood-stained mucus from the bowel, and from 60 to 80 per cent. of the visitors to the island are said to suffer from it. A curious feature about its distribution is that it is almost entirely confined to visitors to the hotels, the dwellers in private houses being as a rule free from the disease. This and other reasons have led Dr. Walker to acquit the milk- and water-supply from the responsibility of causing it, and he has been led to believe that it is due to a bacterial contamination of food, and especially of the meat, by flies, for the precautions taken to keep them out of the larders are very imperfect in the hotels, where also frozen meat is consumed that has been subject to fly contamination in transit. The dwellers in private houses, on the other hand, eat fresh meat almost exclusively and are very careful to keep it free from flies. Dr. Walker has also noticed that people who have partaken of soups and *réchauffés* that have been prepared without bringing them to the boiling-point, as is frequently the case in hotels, often suffer from the symptoms which he ascribes to fly infection of the cold meat from which such dishes are prepared. He concludes his paper with a set of useful suggestions for the preservation of all food from the risk of such contamination and lays stress on the necessity of sterilising by steam all dishes and cooking utensils. It will certainly be worth the while of the hotel keepers of Las Palmas and the neighbouring islands to put their houses in order in this respect, and should the fly theory of the disease be confirmed it is not too much to expect that the local authorities will protect their European visitors by regulations as to the storage and preparation of their food, for the continuance of such a troublesome "epidemic" must seriously jeopardise the popularity of the islands as resorts for the winter, at which season the disease is most prevalent.

PARALYSIS OF THE SUPERIOR OBLIQUE MUSCLE OF THE EYE AS A RESULT OF DIRECT INJURY.

PARALYSIS of the external ocular muscles as a consequence of direct traumatism to the eyeball and orbit is not of very frequent occurrence. Dr. Michael Kos of Przemysl, in a paper published in the *Wiener Medizinische Wochenschrift* of March 14th, states that up to the year 1906 38 cases had been collected from the literature by various observers, and that among them there were only two cases of paralysis of the superior oblique muscle. He records in detail an interesting case observed by himself as a further example. The patient was an artilleryman who sustained a direct injury just above the inner canthus of the right eye owing to losing his balance while mounting a provision wagon and falling in such a way as to cause a projecting piece of iron of the size of the little finger on one of the cross bars of the wagon to penetrate the orbit in the situation already mentioned. Not only were the soft parts lacerated but in addition the orbital plate of the ethmoid bone was fractured, so that on sniffing, air escaped from the wound for two days after the injury. There was considerable swelling of the contused tissues in the wound but healing occurred in nine days. After the bandages were removed the patient found that he was unable to walk properly owing to diplopia. He was therefore admitted into hospital. The site of the injury was indicated by a discoloured area of skin over a swelling of about the size of a pea in the nasal part of the upper lid on the right side. No alteration was observed about the globe of the eye and the fundus was found to be normal. Vision proved to be 6/6. Diplopia was present which the patient endeavoured to overcome by holding his head in a peculiar manner in order to avoid the giddiness which otherwise resulted. The diplopia was confined to the lower half of the field of vision. In the median line the image from the right eye was situated on the right, somewhat lower than the image from the left eye, with the upper end inclined inwards, but the separation of the images was so slight that the upper end of the right image touched the left. On looking downwards and to the left the deviation was at its maximum but the images were parallel. In order to avoid the diplopia the patient adopted the following position. His head was inclined towards the left, somewhat bent forwards, and rotated towards the right. It was evident that the superior oblique muscle was paralysed. There was no indication of any injury to its attachment to the eyeball or to the belly of the muscle itself, although the latter could not be definitely excluded. Dr. Kos suggests that the most probable explanation is that the trochlea itself was lacerated or detached by the fracture. In regard to treatment the faradic current was applied for some weeks without any improvement resulting. No operative surgical treatment was undertaken.

THE EQUINE STEAK.

RIGHTLY or wrongly, sentiment, at any rate in this country, is very vigorously directed against the use of horseflesh for food. The feeling is very strong and not a few persons evince disgust at the mere mention of the suggestion that an equine steak can rival the usual beefsteak as regards flavour and tenderness. But there are connoisseurs who allege that a Chateaubriand steak is all the better from the gustatory point of view when it is prepared from the flesh of the horse. The prejudice against horseflesh has doubtless arisen from a familiarity with the hard-working habits of the animal, and partly perhaps on account of its association with the diet of the cat. There is some idea that hard work renders the fleshy parts of the animal unfit for food and yet in countries where it has been the custom to eat horseflesh the demand is rapidly growing. In Paris, for example, it is reported that last year close upon 50,000 horses were killed for food, this showing an increase of 5000 horses on the figures of the previous year. It would appear, however, that the consumers of horseflesh are to be found chiefly amongst the poor people who are not able to pay the higher prices for beef or mutton. Still, the fact remains that horseflesh is a nutritious meat and it can be prepared in such a way as to be an attractive meat food which need not be tough or objectionable from the point of view of flavour. There are no physiological reasons against the use of it, and indeed the immunity which the horse (unlike the ox) enjoys from tuberculous disease is a decided point in favour of the use of horseflesh as against beef. Prejudice, however, dies hard, and not, perhaps, until the motor has completely driven the horse from a life of toil will its flesh be added to our list of meat foods to relieve the present monotonous round of mutton and beef. Whatever may be said in favour of the value of horseflesh for food, and whether sentiment is right or wrong, there can never be any justification for passing it off as something else. Even in places where horseflesh is a popular food, chiefly in the form of a sausage, the vendors are required to indicate the nature of the article which they sell.

MEDICO-BIOLOGICAL SCIENCE IN THE ITALIAN UPPER CHAMBER.

AN Italian correspondent writes: "His Excellency Signor Giolitti, unlike many Italian premiers, has shown a marked preference for men of science in his selection of names proposed to the King for senatorial honours, nature study and medicine taking precedence of all other subdivisions of the field of knowledge. True to this tradition he has among the eight professors just promoted to the Upper Chamber included five whose distinction has been achieved in biology or medicine. They are the following: Dr. Pio Foà, professor of pathological anatomy in the University of Turin; Dr. Antonio Carle, professor of surgical anatomy and *privat-docent* in clinical surgery of the same school; Dr. Giacomo Filippo Novaro, who holds the chair of operative surgery in the University of Genoa; Dr. Giovanni Paladino, professor of histology in the Neapolitan seat of learning; and Dr. Giovanni Battista Grassi, professor of comparative anatomy and entomology in the University of Rome, whose work in the "campagna anti-malarica" is well known throughout Italy and the English-speaking world. The Italian press comments approvingly on the reinforcement of the Senate by these authorities in their respective subjects, the future of Italy depending largely on the rehabilitation of her people hygienically as well as educationally and socially."

SUCCESSFUL OPERATION FOR PHLEGMONOUS GASTRITIS.

PHLEGMONOUS gastritis is a very rare condition of which only a limited number of cases have been published. In the *American Journal of the Medical Sciences* for May Dr. J. W. Bovée has published a case—probably the first—in which the suppurative form of the disease was successfully treated by laparotomy. A multipara, aged 33 years, was taken to hospital late on the night of Oct. 6th, 1907, by her medical attendant. For several years she had suffered from epigastric pain which was usually relieved by taking food. Her last period occurred on April 13th and she considered herself pregnant. On Oct. 3rd she ate heartily boiled cabbage at dinner and crab late at night. During the night she was attacked with severe pain in the gastric region which required the administration of morphine. On the following day the pain continued and vomiting began. Attempts to move the bowels by enemata and cathartics failed. The temperature ranged from 99·5° to 101·5° F. and the pulse was rapid and weak. On the next day croton oil was given but this also failed to act. Various remedies were administered to relieve the pain and vomiting, but without result. The vomit was at first solid and consisted of partially digested food. Later it was watery and frothy and dark green. On admission the pulse was thready and the expression was anxious. Examination under anæsthesia showed that the uterus extended an inch above the umbilicus and that the epigastrium was distended and tympanitic. An incision was made in the middle line above the uterus. The intestines were congested. The stomach was palpated and found to be fully three-quarters of an inch thick at the middle of the great curvature, gradually thinning towards the cardiac end. At the pyloric end and in front was a soft mass nearly of the size of a fist, which gradually thinned towards the middle of the stomach. The stomach was opened at about the middle by a longitudinal incision about three inches long and the mucosa was inspected. The pylorus would not admit the entrance of the tip of the little finger. In order to determine the nature of the enlargement a short incision was made over it. Gauze was packed around it and on incision two or three ounces of greyish pus escaped. The long incision in the stomach was closed, the abscess was wiped out, and a rubber tube was sutured in and brought out of the abdomen. A light gauze drain was packed about it. The patient was fed by the rectum for 21 days. Five days after the operation liquids were given by the mouth, as saline solution given hypodermically and liquids given per rectum did not quench the patient's insatiable thirst. On the following day the contents of the stomach came through the wound. A few days later solid food was given and the tube was removed. After a few days the contents of the stomach ceased to escape. On the eighth day abortion took place. Except for infection of the abdominal incision, which required resuturing, recovery was uninterrupted. Phlegmonous gastritis is characterised by the sudden onset of pain in the upper abdomen, which is increased by pressure, vomiting, rigors, and fever. If a tumour appears in the region of the stomach presumption of the disease becomes strong and if pus is vomited still stronger. In most cases a positive diagnosis is impossible. Excepting four cases the treatment has always been symptomatic, but the great progress of abdominal surgery will probably lead in the future to more frequent operation. The prognosis is bad; only two patients have been known to recover. In a case reported by Leith considerable peritonitis was present and the peritoneal cavity was washed out. Death occurred seven hours later. In a case recorded by Mr. A. W. Mayo Robson and Mr. B. G. A. Moynihan a gastric ulcer had eroded the pancreas and an abscess of that organ had burst into the stomach, causing acute gastritis. Posterior gastro-enterostomy was followed by recovery. In none of the recorded cases of operation was suppurative phlegmonous gastritis present, as in Dr. Bovée's case.

AN IMPENDING VISIT OF FRENCH MEDICAL MEN TO LONDON.

A MEETING took place at 20, Hanover-square, London, W., on June 4th, to discuss the question of giving a dinner in honour of the group of French medical men who are expected in England in July. Dr. Theodore Williams occupied the chair and explained that the impending visit was under the auspices of the "Voyages d'Études Médicales" which society had, on account of the Franco-British Exhibition, arranged an excursion to London in place of its annual visit to a French watering place. A number of resolutions were carried and it was arranged that a dinner should be given at the Exhibition on Thursday, July 16th, to 150 of our French visitors (ladies included). Those of the medical profession in England who wish to take part in this entertainment are asked to subscribe a sum of not less than 2 guineas to defray the cost of their own dinner and that of a French guest. A limited number of ladies will be included. The following executive committee was elected: Dr. G. Ogilvie, Dr. Leonard Williams, Dr. Leonard Mark, Dr. Dundas Grant (treasurer), and Mr. Macleod Yearsley. Gentlemen who wish to take this opportunity of showing hospitality to our French brethren are requested to communicate with a member of the committee without delay, as the banqueting accommodation at the exhibition is limited to 300.

LOCAL ANÆSTHESIA IN MINOR SURGERY.

THE interest in local anæsthesia which was initiated by the publication of Schleich's *method of infiltration* has steadily increased. There are many methods at present competing for general favour, infiltration, perineural injection with the use of a constricting band, intraneural injection, and modifications of the methods of Oberst, Braun, Krogius, and others. So there are also many local anæsthetics—cocaine, β eucaine, stovaine, alypin, and tropacocaine. The range of operations for which local anæsthesia has been used is ever widening. We may mention those involving skin areas, such as Thiersch's skin-grafting method, removal of superficial tumours, operations on the fingers and toes, removal of small mammary growths, ligature of arteries, extirpation of ganglia, and the more extensive procedures involved in operations upon the tongue, lips, trachea, ribs, and thorax. In some continental clinics goitres are commonly removed under local anæsthesia and besides the radical treatment of hernia abdominal operations of great magnitude have been conducted without using general anæsthetics. No doubt local anæsthesia presents many obvious advantages, and house surgeons, especially those in country infirmaries, will find benefit from acquiring a knowledge of its technique. There are, however, less obvious drawbacks and some reasons which have never been very fully advanced why the indiscriminate use of local anæsthesia by house surgeons should be discountenanced. The technique is not so simple as appears and the best results can only be attained by the most heedful attention to detail. In the rush of hospital work, especially in places where skilled helpers are lacking, it is not easy to obtain that all-important adjunct to the use of local anæsthesia—sterilisation of instruments, of solutions, and of the skin. The time occupied by an operation performed under local as opposed to general anæsthesia is considerably increased, and this is not always unimportant. In cases in which a local œdema may extend into dangerous regions —e.g., the tongue—perils may arise before they are recognised. It cannot be insisted upon too strongly that success in local anæsthesia is obtainable only after much practice and watching the methods when employed by competent exponents. The extreme simplicity of the proceeding like that of injection into the subdural space is such when it is performed by an expert that the observer is prone to imagine that "there is nothing in it" and that anyone can obtain an equally good result. Undoubtedly both local and intrathecal injections afford most valuable aids, the former for minor surgery and both in those rare cases in which general anæsthesia seems contra-indicated. There is, however, a danger lest the methods should suffer by unwise or unskilful use in the hands of those who have failed to recognise that much knowledge, patience, and experience are needed for the success, or even safety, of local anæsthesia and of the lumbar puncture.

THE DRINK CRAVING.

A CASE was heard before the Manchester justices a few days ago which illustrates clearly one of the difficulties met with in attempting to reclaim the chronic drinker by detention in an inebriates' home, in the hope, of course, that after two or three years' abstention from drink the craving for it may be lost. The case was that of a middle-aged woman charged with drunkenness, and this, it was said, was her forty-first appearance before the court. She had been in the inebriates' home at Langho for three years, was said to be a splendid worker when not in drink and a very good laundress. The chairman said that the magistrates were disposed to send her for a further term of three years to the home. There was something pathetic in the woman's reply. "She had tried her best to keep off the drink, but it seemed she was always getting into the hands of the police." She said further that she did not suppose three years would do her any good, "because the being in a home upsets one's mind and makes you worse when you come out again." This will accord with the experience of many who have to deal with such cases. The craving is not lost but only rendered impossible of indulgence for the time being. There may be a sincere wish "to keep off the drink," but when the chain is loosed the weak will has no chance against the cruel, merciless craving which wrecks once more even her own hopes of escape from what seems an irresistible fate. There was some further dialogue between the chairman and the drunkard, the former saying, that if you go with a determination not to benefit "I dare say there is something in what you say," but if you make up your mind that it will be better for you and that when you come out you will turn over a new leaf, "then you will be all right" It is to be feared, however, that the chairman's well-meant counsel was prompted more by hope than experience, which latter would chime in rather with her answer, that "unless a man or a woman, under my circumstances, absolutely leaves drink alone, no punishment will benefit them. I have tried it, and I know." She was committed again for three years to Langho, but what will be the result of this further experiment? Putting aside the quack remedies for the drink craving, the ill success attending their use scarcely justifying their serious consideration, we are left apparently to one plan as being the most merciful to the victims themselves and their families, and most assuredly the best for society. This, of course, is permanent detention. It would have to be administered carefully and proper safeguards against abuse would be required, while the conditions justifying and requiring such detention would have to be most carefully and humanely considered. It is thought right to confine lunatics, no doubt with, in some cases, good hopes of benefit, but also as a protection from themselves and as safeguarding others. The same reasoning may be applied to these cases with equal fitness.

METROPOLITAN HOSPITAL SUNDAY FUND.

A MEETING of constituents of this Fund will be held on Monday next, June 15th, at 3 o'clock, at the Mansion House, London, the Right Hon. the Lord Mayor presiding, when a marble bust of the late Mr. George Herring, the munificent benefactor to the Fund, will be unveiled. The presentation will be made by the Hon. Sydney Holland (one of Mr. Herring's executors), while Bishop Lawrence of Boston, Massachusetts, and Mr. Henry Morris, President of the Royal College of Surgeons of England, will address the meeting in support of the objects of the Fund.

THE Cavendish lecture will be delivered before the West London Medico-Chirurgical Society on Friday, June 26th, at 8 15 P.M., by Sir William Whitla, M.A., M.D. R.U.I., LL.D., in the Town Hall, Kensington, London, W. The subject is the Etiology of Phthisis. The President of the society is Mr. R. Lake, F.R.C.S. Eng , and the honorary secretaries are Dr. F. G. Crookshank, D'Antraigues, The Terrace, Barnes, S.W., and Mr. A. Baldwin, F.R C.S. Eng., 6, Manchester-square, London, W., who are now sending out invitations to be present on the occasion and to whom any communications should be made.

THE annual banquet of the Association of British Postal Medical Officers "to meet the Right Hon. Sydney Buxton, M.P., His Majesty's Postmaster-General," will be held at the Whitehall Rooms of the Hôtel Métropole on Tuesday, July 14th, at 7.30 P.M. The President, Dr. George A. Mason. M.A. Camb., will occupy the chair. The secretary of the dinner is Dr. R. Ritchie Giddings, Hillsborough House, Mansfield-road, Nottingham.

THE annual general meeting of the Medical Officers of Schools Association will be held at 11, Chandos-street, W., on Wednesday, June 17th, at 3.30 P.M., when Mr. John Hayward will open a discussion on the recent memorandum issued by the Board of Education to local education authorities *re* the medical inspection of elementary schools.

THE Governor of Hong-Kong has stated in a despatch to the Secretary of State for the Colonies that 133 cases of plague with 109 deaths were reported during the week ending June 1st. In the previous week 114 cases with 95 deaths were reported from that colony.

THE INTERNATIONAL FIRST AID CONGRESS.—The exhibition which is being held in connexion with the International First Aid Congress at Frankfort-on-Main was opened on June 6th. The first-aid section of the exhibition includes a large number of appliances which cannot fail to attract the attention of everyone interested in the humane work which the exhibits illustrate. Particular interest is shown by visitors in an improved rocket apparatus which is described as an aerial torpedo for life-saving at sea, for use from either shore to ship or from ship to shore. It consists of a line 500 yards in length, carried by a torpedo four inches in diameter and 20 inches in length. Its chief features are its portability and the ease and accuracy with which it can be manipulated.

THE LANCET

SPECIAL SUPPLEMENT

IN SUPPORT OF THE

METROPOLITAN HOSPITAL SUNDAY FUND

Published in aid of the Appeal to be made on Sunday, June 21st, 1908.

> "So many are
> The sufferings which no human aid can reach
> It needs must be a duty doubly sweet
> To heal the few we can."—COLERIDGE.

FOR more than twenty years THE LANCET has claimed the aid of those into whose hands its Supplement may fall on behalf of the suffering poor of London, and of the Metropolitan Hospital Sunday Fund. The appeal thus made on "Hospital Sunday" is addressed in the first place to those who, on that day, attend religious services in places of worship where collections in aid of the Fund take place, or in the case of members of the Jewish faith to those who on the preceding Saturday have the opportunity of contributing brought directly to their notice. In the second place it is hoped and believed that many who on the two days mentioned are not attending Divine worship in London or in any other locality where collections are being made on behalf of the Metropolitan Hospital Sunday Fund nevertheless will desire to aid. And all who have it in their power to do so are urged to remind these absentees to give, as well as to give themselves. Moreover the putting of it into the mind of others to give may well play an important part in the present year, 1908, for not only in the ordinary course of metropolitan life in summer many who usually dwell in London will be absent from it on Hospital Sunday, but there are also in our midst an unusual number of foreigners. At peace with all mankind, we are celebrating and cementing our friendship with the great nation across the Channel in a joint exhibition held in order to display to one another and to the world our achievements in the spheres of industry and of art, while the great exhibition does not stand alone as an attraction to bring foreigners within our walls. Those who come do so either in the pursuit of pleasure or of profit; it is not to be supposed that they will grudge a contribution to our great charities if they are but made aware of their existence and of their needs. The beggar knows well in all countries that in the foreigner he will find a sympathetic listener to his tale. The tale told by the hospitals is an oft-told story of need, of life lived from hand to mouth, of suffering endured by men and women; but, unlike that of other mendicants, their need is real; they work as well as beg, and it is on behalf of others that they work, it is upon others that they bestow the alms which they obtain; their doors are opened to native-born Briton and to foreigner alike. May we not then urge that all who have the power to do so should bring the Metropolitan Hospital Sunday Fund's need home to our visitors. If they are attending Divine worship in our midst they will become aware that Hospital Sunday is a special occasion falling but once a year, but otherwise they may leave London without ever hearing of the existence of the Metropolitan Hospital Sunday Fund. To remind others may be to some a less welcome duty than to give themselves, but none the less the Fund cannot afford to lose because it has failed to draw attention to itself at the right moment. To all, therefore, we appeal to influence the generosity of others no less than to exercise their own.

Why all should give.

We are aware that we are dwelling upon a tale not twice told but re-iterated many times in the past, and to be repeated by us, we hope, during many years to come, when we press the claims of the hospitals upon all, making no exceptions, and "sparing neither age nor sex." Neither rich nor poor can claim any right to be exempt from a tax to which all are invited to assess themselves according to their means, and from which all will benefit, in varying degrees, according to their needs. When a sudden emergency occurs, and the rich man injured in a street accident requires that aid which would come too late if he were to wait to be conveyed to his house or to the private nursing home, the doors of the hospital are open to him, and he may be carried through them side by side with some nameless

to the wards for infirm and insane women. My evidence described how lunatics were confined in the same ward as patients suffering from chronic complaints such as cancer, under the charge of a pauper attendant who had not a particle of feeling, and who, in fact, appeared to be possessed with that inborn love of cruelty which seems innate in some strange natures." In explanation of the "pauper attendant," it must be mentioned that in the workhouse described the nurses for the sick in the infirmary were neither more nor less than inmates of the able-bodied women's ward, who were there usually because they were irreclaimable drunkards, and who were rewarded for their services as nurses by being allowed half a pint of beer at their supper. woman fastened to a bedstead by means of a sheet, which was bound tightly round her confining her arms. The sun streamed on her face through the blindless window and her lips were parched and dry. The word 'water' sent me back in all haste to the ward, where I desired the woman who was taking Mrs. E.'s place to give me some at once. This she refused to do, saying that she did not dare do anything without orders." In the end the writer, from whose reminiscences we are quoting, herself discovered a mug and a tap and took the responsibility of giving a drink of water to the suffering patient. She was thanked with gratitude, but whether the person thus treated was supposed to be out of her mind or was being punished for insubordination as a patient, she did not discover. Referring again to the stick above mentioned, she writes, "On inquiry as to its use from the decrepit old creature who slept next to Mrs. E., I was told in a frightened whisper that the pain she suffered sometimes at nights made her groan aloud, but she always tried hard to prevent it, as so sure as she made a sound the stick was brought down upon her at once to make her silent." Once after seeing an old woman knocked down by Mrs. E. the lady visitor complained to the matron, but was told that nothing could be done while the system prevailed by which the so-called "nurses" were chosen from the inmates of the able-bodied women's ward. On the only occasion on which a complaint to the master was ventured upon his reply was a threat that the guardians would

STATISTICS OF HOSPITAL WORK IN LONDON DURING THE YEAR 1907.

* We reproduce the term "General Hospitals" as employed by the Council of the Metropolitan Hospital Sunday Fund.

n exception was made in favour of Mrs. E., the cruel nurse above referred to, in that she received a wage in addition to her half-pint of beer, in consideration of the arduous nature of her services. She is described as a strong, muscular person, and she "kept a strong stick always at hand in case any patient should be noisy or refractory. If patients became violent her usual practice was to drag them by their hair down the passage and throw them headlong into the padded room. In one of my visits there on a very hot day it chanced that Mrs. E. had been called away for some reason and the ward, for the time, was left in charge of the wretched old pauper assistant. Hearing loud cries and moans proceeding from the passage as I entered, I threw open the door at once and became aware of a young

the names of Charles Dickens and of Charles Reade will occur readily in such a connection, but further elaboration of our point hardly seems to be needed. Times change, and those who change with them by the irresistible laws of progress feel that the improved circumstances are necessary and right. If, then, poor-rates have been allowed to rise in order that workhouses may meet the claims of a newer age, surely we may appeal to our readers to tax themselves voluntarily upon a higher scale than once was asked of them, in order that our hospitals may ever conform to the spirit of that age. If in the humane treatment of the suffering poor those hospitals have set an example to the world, assuredly they have a claim upon us all for help that they may hold their own in their path of progress.

exclude the visitor from the wards if she made a fuss. Of the care of children in the same institution we read in another passage, "There were usually two children sleeping in each bed, and to show what a total want of care and supervision there was here, I have actually seen once a little child with measles in the same bed with another with a broken leg."

We have quoted enough to illustrate our point, and we repeat that we do not suggest that horrors of the kind described existed in the hospitals of 1866, the date to which these memories of a bygone workhouse refer. We do, however, invite our readers to try to imagine such things taking place in the present day in London, and to realize that the change which renders them impossible is due to an altered and developed public opinion which demands that the poor in workhouse infirmary and in hospital alike shall be treated in a manner undreamt of less than fifty years ago. We might corroborate the above account by reference to many writers of fact or of fiction, and

the names of Charles Dickens and of Charles Reade will occur readily in such a connexion, but further elaboration of our point hardly seems to be needed. Times change, and those who change with them by the irresistible laws of *progress* feel that the improved circumstances are necessary and right. If, then, poor-rates have been allowed to rise in order that workhouses may meet the claims of a newer age, surely we may appeal to our readers to tax themselves voluntarily upon a higher scale than once was asked of them, in order that our hospitals may ever conform to the spirit of that age. If in the humane treatment of the suffering poor those hospitals have set an example to the world, assuredly they have a claim upon us all for help that they may hold their own in their path of progress.

A Year for Special Effort.

If, however, we appeal for renewed and increased generosity in order that the hospitals may not fall behind in efficiency, we cannot altogether ignore those special circumstances which at this particular time may render it difficult for some donors to *exercise* their liberality on a scale such as they *would desire*. The past few years have not been marked by any such prosperity in the City of London as would enable us to expect any growth of the Metropolitan Hospital Sunday Fund traceable to it. Complaints as to the condition of "trade" are heard alike from those whose dealings of various kinds are on a large scale and from those whose business is retail, and poverty is pleaded, we are aware, in answer to many appeals, and is pleaded, moreover, by others whose incomes are not directly dependent upon commerce. It is for this reason that we insist most earnestly upon the necessity for all to give in the present year, 1908, to the fullest extent of their powers, supplementing the charity of others who may be absolutely compelled to diminish their annual contributions to charity, and exercising to the full that self-denial which renders the gift more worthy. The contribution to the Metropolitan Hospital Sunday Fund is *not one which can be left to stand over until* "better times." We make no comparison with the different *objects upon which the money might otherwise be bestowed*, but we would point to the ceaseless and *pressing need of the sick and suffering*.

We are all hoping for "better times," the hospitals no less than the generous persons who help them, but whereas the member of the public can curtail his expenses, the hospitals cannot do so without abandoning the very motive and aim of their existence. It is true that an individual institution may close a ward or two and reduce its expenditure upon that portion of its building to the upkeep of its fabric, but what of those who should be filling the beds in those wards? Their sickness and suffering are not postponed until a place is ready in which they may be alleviated. The operation which might save *limb or life cannot stand over* till trade improves and money flows more freely in its accustomed channels. The poor cannot wait to be healed, because to them sound health means the condition in which they can work to support themselves and their families, and that which incapacitates them from work means misery, loss of home, and of all that renders life tolerable to them. The life of the worker, which might be saved by prompt assistance, may be lost if he has to wait before it can be rendered. Therefore the hospitals cannot wait.

Sick and sound alike should sympathise.

With this urgency of the sick man's need *those* should sympathise especially who have endured sickness, or have undergone operations at *the* surgeon's hands, and who are asked to realize what it means to lie idle in a humble home waiting *for* relief until a bed is vacant in a hospital, *or to be* referred from one institution to another because the wards of the first are full. These surely will not let their gifts to the hospitals wait until a year *or two* hence their pockets may be fuller. To the *sound* in health the contribution to the hospital *should* be a thankoffering increasing year by year *in order* that others may attain that which the giver enjoys. That which many spend light-heartedly in a day or two, or, indeed, in a few hours of enjoyment, perhaps in health-giving exercise, perhaps in visiting the music-hall or theatre, perhaps in luxuries of food and drink, might, if saved, augment their gift to the Metropolitan Hospital Sunday Fund far beyond its usual dimensions. It would be well saved by such self-denial; it would be well spent in helping to restore to health those to whom bodily activity means the power to work; to whom rest from pressing anxiety and suffering is perhaps the highest material pleasure for which they can hope. If we suggest that for many there is no need to do more than to tax their luxuries in order to give, we do so in the consciousness that the expenditure upon luxuries and upon pleasures of all kinds is very great in modern London, and in the belief that we are asking for no overwhelming sacrifice on the part of those to whom we address ourselves. In particular we would urge generosity, even at the expense of private pleasure, upon the young; not only upon little children, but upon those who have quitted childhood, and, in the ardour of youth, pursue their own pleasures, perhaps forgetful of the pain of others. Many of these may only need to be reminded, and their hearts will prompt them to be liberal.

1884. Including £4500 from the International Health Exhibition.

1885, 1886, 1887. Including three donations of £1000 each from Dr. James Wakley, Editor of THE LANCET.

1891. Including £5000 from the late Duke of Cleveland, &c.

1894. Including a legacy of £5000 (less duty) from the executors of the late Mr. W. J. Whitaker.

1895. Including £10,000 from Messrs. Barnato and friends; £3400 from the Stock Exchange; £1000 from Lord Iveagh; and £1000 from Mr. J. B. Robinson.

From 1891 to 1896 Sir Saville Crossley, Bart., P.C., M.P., gave an annual donation of £1000, and since has divided his contribution between this Fund and King Edward's Fund.

1897. Jubilee year. H.R.H. the Prince of Wales started a Special Fund for Hospitals.

1899. Including £10,000 from Mr. George Herring, and £1050 from Mr. J. Lane Densham.

1900. Including a further £10,000 from Mr. George Herring, £1090 from Mr. Thos. King, and "F. H." £1000.

1901. Including a further £10,000 from Mr. George Herring, and £4000 from Sir F. Cook, Bart., M.P.

1902. Including a further £11,575 from Mr. George Herring, and £1000 from Mr. Charles Morrison.

1903. Their Majesties the King and Queen, with most of the other Members of the Royal Family, attended at St. Paul's Cathedral. Including a further £12,302 from Mr. George Herring.

1904. Including a further £11,926 from Mr. George Herring.

1905. Including a further £12,400 from Mr. George Herring, and £12,500 from the executors of Mr. F. W. Cook.

1906. Including a further £11,000 from Mr. George Herring and £3000 on account of the legacy bequeathed by Mr. Herbert Lloyd.

1907. Including £30,000 from the late Mr. George Herring's estate, and a second instalment of £3000 on account of the bequest of the late Mr. Herbert Lloyd.

The Hospitals a gift from those who have to those who have not.

In conclusion, the contributions asked for by the Metropolitan Hospital Sunday Fund are charitable gifts essentially. The conditions and disabilities attaching to the receipt of poor law relief, and a certain confusion in some minds between benefits bestowed in the spirit of charity, rightly so-called, and the official doling out of funds obtained by levying a rate, have caused a certain stigma to attach to the term "charity." Those, moreover, on whom rates are levied pay a compulsory tax at the bidding of the State to be distributed by the local authority, and even the most benevolent and public-spirited among us can hardly claim that we pay our taxes with cheerful willingness, or that in doing so we are filled with kindly thoughts for those upon whom the moneys so levied will ultimately be expended. The gift of charity to the hospitals is upon a different footing; it blesses him who gives no less than it benefits its recipient, because the only compulsion upon the giver is imposed by his conscience and by his kind heart when he thinks of others in less fortunate circumstances than his own. All this might be ordered otherwise. The hospitals might be made into institutions maintained out of the rates, governed by the county or borough council, supervised by a Government department, enmeshed in red tape, and with no need to apply to the charitable for assistance. Who would be benefited by such a change? Would the sick and injured needing prompt and effective help? That is inconceivable, for now the hospitals are under the rule of those who have made them what they are, and who in their zeal on behalf of their fellows have built and organized them voluntarily for the rendering of such help and for no other object. Would the charitable gain? They would lose the object of their charity; the occasion to think of others would be gone, and the need for self-denial in order to increase their gifts would no longer be felt. On the other hand, the necessity to maintain the hospitals would still be there, imposed by statute, and enforced by the rate collector, so that the mention of the word

SUMMARY OF TABLES.

Total	£68,134	143,000	45,913	72,537	11,697	9,756	9,323	6,558,581	470,849

"hospital," or of the poor man's need in sickness, would but call to mind the irksome burden of a tax from which bygone generations were free. To those who now by their self-denying generosity maintain the hospitals, the law-imposed necessity to give would afford no pecuniary relief. In the first place they ask for none, and in the second the hospitals maintained out of the rates would be institutions so much more costly than those now aided by charity that the sum at present required annually can hardly guide us in estimating the amount of the rate imagined.

For we must consider to whom such hospitals would be open? The large class which now has free education provided for, its children occurs to us at once in making such a calculation. To any of this class when his case is urgent such an institution now opens its doors. Would the rate-maintained civic hospital be compelled so to discriminate, or would it be likely to do so, having no question of the proper application of its limited income to consider? Would it not be open to all on demand and for all kinds of treatment, just as the public elementary day schools are open to the children of all? The rate in such circumstances would indeed be a heavy one; and would it be economically administered? Under the present system hospitals, by strict economy and by living from hand to mouth, maintain the high standard of efficiency which modern science demands, and we may here point out that the promotion and maintenance of economy and efficiency have been among the principal objects kept in view and insisted upon by those distributing the Metropolitan Hospital Sunday Fund ever since its inception. The hospitals might not fall below their present standard under the eye of a State department, but would that eye be all-seeing where the economical expenditure of easily obtained funds and the getting of "value for money" were concerned? The answer to this question may be obtained, in part, at least, by the perusal of reports recently published of official inquiries, and of legal proceedings, which have revealed reckless extravagance and in some cases alleged corruption in the administration of funds entrusted to elective local authorities. No, the generous public who maintain the hospitals of London by their free gifts, whether great or small, have nothing to gain from the municipalisation of the hospitals.

If, however, the hospitals of London are to retain their high position among the great charities of the world, the outpouring of benevolence must be liberal, and the collection of the Metropolitan Hospital Sunday Fund places before all an opportunity for the rendering of that outpouring universal. None need shrink from giving because his gift must be but small, or because he shrinks from seeing it contrasted with that of his richer neighbour. As the hospitals open their doors to all alike regardless of differences of religion or of race, provided only that poverty and suffering qualify them to receive, so the appeal is made to all whose circumstances enable them to give, however small the gift may be, and whatever may be the creed or the nationality of the giver.

The appeal is made to the vast population of London and of its neighbourhood; to the loyal subjects of His Majesty King Edward VII., who himself has not only instituted another hospital fund which bears his name, but who with his beloved Queen and with the members of his family has ever shown a deep and sympathetic interest in the financial welfare and in the working efficiency of the hospitals. It is made also to those strangers in blood who sojourn among us for longer or shorter periods and whether they may do so for business or for pleasure. It is made to the rich and to those who by comparison with the "rich" reckon themselves "poor." In responding to it, in giving and in reminding others to give, these will all be united by common goodwill, each doing his utmost in a common cause.

> "Pity and need
> Make all flesh kin. There is no caste in blood
> Which runneth of one hue, nor caste in tears
> Which trickle salt with all."

Audited and found correct, this 21st day of November, 1907.

(Signed) W. H. PANNELL & Co., *Chartered Accountants*, 13, Basinghall-street, E.C.

⁎⁎ In the preparation of the voluminous statistics of hospital work which have been here digested and exhibited in collected form (and which have been specially supplied to us in response to our applications, and are quite independent of any returns made to the Metropolitan Hospital Sunday Fund Committee), we have been greatly indebted to a large number of secretaries and other officers of the various medical charities of the metropolis. To them we desire, as on many previous occasions, to tender our sincere thanks.—ED. L.

MEDICINE AND THE LAW.

Insanity a Bar to Valid Marriage.

THE case of Jackson v. Jackson recently heard by Mr. Justice Bargrave Deane in the Divorce Court was a wife's suit for nullity of marriage on the ground that at the time of the marriage her husband was suffering from paranoia or delusional insanity and incapable of contracting marriage. The facts were as follows: Catherine R. Jackson, *née* Macfarlane, went through a ceremony of marriage on Oct. 8th, 1904, with H. P. M. Jackson, at St. Luke's Church, Kensington. There was a child born on Oct. 25th, 1905. It appeared that since the respondent had returned from the South African war in 1902 he had been subject to delusions, the main ones being that there was a conspiracy or plot to injure him, that his letters were being tampered with, that he was impotent, and that he constantly heard voices. It was not disputed that he went through the ceremony as an ordinary individual would have done, but during the honeymoon in Italy the delusions gradually became more marked, and he also then alleged that his wife had been unfaithful. On March 18th, 1905, Mr. Jackson was certified as insane and was removed to a private asylum. On behalf of the respondent it was urged that the delusions were not such as to affect his capacity to enter into a contract of marriage. Mr. Justice Bargrave Deane in giving judgment said that there were a number of cases which must guide the court but that each case must in a great measure depend upon its own facts. The principle running through the cases was to the effect that the court must take into consideration the nature of the alleged unsoundness of mind and see whether it was of sudden or progressive growth. When the unsoundness of mind had been proved to be progressive a decree had been granted. In the present case it was, therefore, necessary to see how far back the insanity could be traced. The law was clearly laid down in Hunter v. Edney by the late Lord Hannen who said: "The question which I have to determine is not whether the respondent was aware that she was going through the ceremony of marriage, but whether she was *incapable of understanding* the nature of the contract she was entering into, free from the influence of morbid delusions upon the subject." His lordship referred to the evidence of the respondent's conduct on his honeymoon in Italy, and continued: While on the continent the respondent complained that he was being watched, spied upon, and that signals and signs were being made about him, and that everybody was laughing at him owing to his impotency. That last delusion was a very material one because the evidence showed that it had existed before marriage as well. It was possible for a man to have such an opinion before marriage but there could be no such delusion after. In the present case the delusion continued, for even after the petitioner had informed him that she was *enceinte* he still expressed the belief that he was impotent. After their return to England the disease had so progressed that the respondent was certified as insane and had been pronounced incurable. The eminent alienists who had been called agreed that "paranoia" was incurable and a disease of progressive growth. One of the experts had expressed as his opinion that the disease in the present case dated from the return of the respondent from South Africa. It was therefore for the court to determine whether the respondent was on Oct. 8th, 1904, capable of understanding the nature of the contract he was entering into, free from the influence of morbid delusions upon the subject. The burden of proof was on the petitioner, and in his opinion she had succeeded and had clearly established that the respondent's disease was of gradual growth and had existed long before the parties became acquainted. Therefore there would be a decree *nisi* of nullity. It may be added that insanity or want of reason is a bar to marriage on the ground that without consent there can be no contract, and that where there is no reason there is no power of consent. Mere weakness of understanding is not enough, but there must be proof of incapacity to enter into the contract, the extent of the incapacity being a question of fact to be proved by evidence which to a large extent in such cases must be that of medical experts. A person on recovering sanity may institute proceedings to set aside a marriage entered into when *non compos mentis*, and if insanity at the time of the formation of the contract is proved the marriage will be declared void.

Casual Employment under the Workmen's Compensation Act.

A point of importance under the Workmen's Compensation Act, 1905, made clear by a recent decision of the Court of Appeal, is worth noting by medical practitioners. The wife of a member of the Stock Exchange employed a man to clean windows at their residence and he, while doing so, fell and was killed. The claim against the stockbroker made by those dependent on the deceased workman was resisted on the ground that he was a person casually employed only and not one of those so employed who are entitled to the benefit of the Act which does not include under the term workman "a person whose employment is of a casual nature and who is employed otherwise than for the purposes of the employer's trade or business." The Master of the Rolls in giving judgment pointed out that the employer, a stockbroker, could not be held to be employing a man for the purpose of his business who was only engaged to clean the windows at his private house and said that he interpreted the Act as intended to benefit a workman employed by another for the purpose of that person's trade or business in spite of the fact that such employment was casual only but that it was essential that the employment should be for the purpose indicated. A good many people, no doubt, insure against accidents happening to those whom they may employ casually, with a view to protecting themselves in the event of claims being made by window cleaners, charwomen, luggage porters, and the like. If they do employ such persons but not for any trade or business purpose, having perhaps no trade or business, they are not legally liable for accidents happening to them. At the same time it must be remembered that claims, though baseless, may yet be made, that the employer may have some difficulty in resisting them, and that he may require legal aid in doing so. It may therefore be prudent to insure in respect of accidents that may happen to a casual workman, although there may be no apparent liability, in order to have the assistance of the insurance company in defeating a possible claim which in no case should succeed. In the instance referred to above compensation had been allowed in the county court and in the Court of Appeal the employer had the assistance of very eminent counsel. This question of accidents to casual workmen affects medical men in particular, because the premises in which they exercise their profession are usually part of, or connected with, their homes, and the casual workman may be engaged at one moment upon work for the purposes of the trade or business of his employer and at another upon something quite independent of it, and the employer's liability will vary accordingly. For example, a window cleaner falling and injuring himself when cleaning the window of a consulting room can apparently enforce a right to compensation which he would not possess after a similar accident due to cleaning the window of the drawing-room, and we can imagine a severe legal fight on the point under discussion arising out of such an accident if the man fell while cleaning the dining-room window, and if it was proved that that apartment was sometimes used for meals and sometimes as a waiting room for patients. The necessity for insuring against accidents to casual workmen is therefore one peculiarly affecting medical practitioners.

Looking Back.

FROM

THE LANCET, *SATURDAY*, June 12th, 1830.

PROTRACTION OF VEGETABLE LIFE.

THE following extraordinary instance of the lengthened period of time during which the vital principle of vegetables may be preserved, was mentioned by Mr. Houlton in the course of his introductory lecture as professor of botany, at the last meeting of the Medico Botanical Society. A bulbous root, which was found in the hands of an Egyptian mummy, and in which situation it had very probably been for more than two thousand years, germinated on exposure to the atmosphere, though, when discovered, it was apparently in a state of perfect dryness. The root was subsequently put into the ground, where it grew with readiness and vigour.

LYNN THOMAS AND SKYRME FUND.

THE following subscriptions have been received between May 29th and June 5th by Mr. William Sheen, M.S. Lond., F.R.C.S. Eng. (2, St. Andrew's-crescent, Cardiff), honorary secretary to the fund.

Subscribers of Seventeen Pounds Thirteen Shillings and Sixpence.

Westminster Division of the British Medical Association, per Harvey Hillard. (Full list of names will be published next week.)

Subscribers of Ten Guineas.

Clinical Society of Manchester, per Gordon Fitzgerald.

Subscriber of Five Pounds.

Anonymous.

Subscribers of Four Pounds Twelve Shillings.

Blackburn Division of the British Medical Association, per Howard Henry, the amount being made up as follows:—

Half-a-Guinea from—

J. T. Ballantyne.
M. Bannister.
E. D. S. Heyliger.
F. W. Taylor.

Ten Shillings from—

John Barr
William Moir

Five Shillings from—

Dr. Arnold.
Andrew Baxter.
Dr. Geddie.
Howard Henry.
T. T. Maclin.

Half-a-crown from—

J. W. Miller.
E. M. Payne.

Subscribers of Four Pounds Five Shillings.

Wigan Medical Society, from some of the Members, per John Blair.

Subscribers of Three Pounds Three Shillings and Sixpence.

Portsmouth District of Southern Branch of the British Medical Association, per B. H. Mumby.

Subscriber of Two Guineas.

John W. Stephens, Cardigan.

Subscribers of One and a Half Guineas.

Wolverhampton Branch of the British Medical Association, per J. Alfred Codd, being half a guinea each from the following—

Anon.
J. T. Harthill.
H. Malet.

Subscribers of One Guinea.

Thomas Baker, Waterlooville, Cosham, Hants.
R. A. Cowie, Ebbw Vale, Mon.
Mark Jackson, Purley.
Edgar Haydon, Newton Abbot.
G. W. Homan and F. W. Rowland, Lichfield.
James Hussey, Farnham, Surrey.
E. R. Williams, Carmarthen.
S. Wallace, Cardiff.

Subscriber of Half-a-Guinea.

W. Macphail, Coatbridge, N.B.

Subscriber of Ten Shillings.

John Jones, Dolgelly.

Subscriber of Five Shillings.

William Cash Reed, Liverpool.

Subscriber of Half-a-Crown.

A Friend.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

THE annual general meeting of this society was held on May 14th at 11, Chandos-street, *Cavendish-square*, Dr. G. FIELDING BLANDFORD being in the chair. Seven directors were elected to fill the vacancies in the court. A cordial vote of thanks was passed to the editors of the medical journals who from time to time publish notices of the society.

The report for 1907, which was adopted, stated that during the past year 11 new members were elected and ten died. The society consists at the present time of one honorary member, 144 life, and 144 paying members, making a total of 289, which, considering the number of medical men who are eligible for membership, is but a very small proportion. The invested funds amount to £99,260, from which is derived in interest the sum of £3118 2s. 5d.; £433 0s. 3d. were received in subscriptions and donations. Amongst the annuitants of the charity—namely, 49 widows and 17 orphans—the sum of £3151 10s. was distributed. 43 widows received £50 each, four £40, one £30, and one £25 with £10 extra at Christmas, and each orphan £12 and £3 extra at Christmas.

The Copeland Fund is a special fund which enables the society to grant to any widow or orphan already in receipt of the society's ordinary relief, extraordinary relief in special circumstances of unusual distress such as blindness, paralysis, insanity, severe disabling accident, or grave permanent disease, and to continue such extra relief in the case of orphans beyond the age of 16 or 18 years (at which, under the society's existing by-laws, the ordinary relief ceases) for such further period as the court of directors may think fit.

During the year two widows in receipt of grants died. One, whose husband had paid in subscriptions £26 3s., had received £490, and the other, whose husband had paid in annual subscriptions £27 6s., had received £2824: she had been in receipt of grants since 1866. Two widows were elected during the year, and on Dec. 31st there were 48 widows and 16 orphans in receipt of grants. One of the widows has been on the books since 1854 and has already received over £2060. Relief is only granted to the widows and orphans of deceased members who have paid their annual subscription for three years or who are life members. During the year nearly 50 letters were received from widows of medical men, who, in many instances, had been left practically penniless, asking for relief, but this had to be refused as their husbands had not been members of the society.

The directors cannot too strongly urge upon the members of the medical profession, especially the younger ones, the desirability of joining the society. Membership is open to any registered practitioner who at the time of his election is resident within a 20-mile radius from Charing Cross. Should any member remove beyond the limits of the society he nevertheless continues to be a member.

The annual subscription is 2 guineas; every member who has paid this sum for 25 years becomes a member for life. Life membership may also be obtained by the payment of one sum, varying with the age of the applicant. Further particulars and application forms may be obtained from the secretary at the offices of the society, 11, Chandos-street, Cavendish-square, London, W.

The meeting closed with a vote of thanks to the chairman.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8731 births and 3958 deaths were registered during the week ending June 6th. The annual rate of mortality in these towns, which had declined in the four preceding weeks from 14·2 to 12·6 per 1000, rose slightly to 12·7 in the week under notice. During the first ten weeks of the current quarter the annual death-rate in these towns averaged only 14·4 per 1000, and in London during the same period it did not exceed 14·0. The lowest annual death-rates in the 76 towns during the week under notice were 6·4 in Walsall, 6·9 in Handsworth (Staffs), 7·4 in Aston Manor, 7·9 in Bury, 8·5 in Tynemouth, 8·9 in Reading, and 9·0 in Hornsey; the rates in the other towns ranged upwards to 17·4 in Grimsby, 17·7 in Stockton-on-Tees, 19·4 in Stockport, 19·9 in Hanley, 20·9 in Merthyr Tydfil, and 24·5 in Swansea. The death-rate in London during the week did not exceed 11·6. The 3958 deaths in the 76 towns during the week showed a further decline of 185 from the numbers returned in the four preceding weeks, and included but 354 which were referred to the principal epidemic diseases, against numbers declining from 445 during the nine preceding weeks; of these 354 deaths, 103 resulted from whooping-cough, 83 from measles, 67 from diarrhœa, 45 from diphtheria, 33 from scarlet fever, and 23 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases last week were equal to an annual rate of 1·1 per 1000, against 1·2 per 1000 during the nine preceding weeks; the rate from these diseases in London did not exceed 0·9 per 1000. No death from any of these epidemic diseases was registered last week in Willesden, Walsall, Huddersfield, St. Helen's, or in nine other smaller towns; the annual death-rates from these diseases ranged upwards, however, to 2·6 in Reading, 2·7 in Preston, 3·4 in Norwich and in Merthyr Tydfil, and 3·9 in Stockton-on-Tees. The fatal cases of whooping-cough in the 76 towns, which had been 114 and 75 in the two preceding weeks, rose to 103 last week; this disease caused the highest death-rates, 1·5 in Smethwick and in Burnley, 1·7 in Barrow-in-Furness, and 2·2 in Warrington. The deaths from measles, which had been 100 and 72 in the two preceding weeks, rose to 83 in the week under notice, the highest rates being 1·3 in Preston, 1·6 in Rhondda, and 2·9 in Stockton-on-Tees. The 67 deaths from diarrhœa was the highest weekly number this year; the mortality was highest in Hanley, Middlesbrough, and Merthyr Tydfil. Of the 45 deaths from diphtheria, which showed an increase upon the numbers registered in the five previous weeks, 13 occurred in London and three in Salford. The 33 deaths from scarlet fever showed a slight decline compared with the numbers in the two preceding weeks and included ten in London and two in Tottenham, in Reading, in Grimsby, in Liverpool, and in Bradford. Three of the 23 deaths from "fever" were registered in London and three in Norwich. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had declined from 2938 to 2753 in the five preceding weeks, further declined to 2648 on June 6th; 291 new cases were admitted to these hospitals during the week under notice, against 330 and 334 in the two preceding weeks. The deaths in London referred to pneumonia and to other diseases of the respiratory organs, which had steadily declined from 301 to 147 in the six preceding weeks, further fell to 132 during the week under notice, and were 37 below the corrected number in the corresponding week of the five years 1903–07. Only nine deaths were directly referred to influenza in London, showing a marked decline from recent weekly numbers. The causes of 39, or 1·0 per cent., of the deaths registered last week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were again duly certified in Leeds, Manchester and Salford, Bristol, West Ham, Bradford, and in 52 other smaller towns; eight uncertified causes of death were, however, registered in Liverpool and seven in Birmingham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 15·4 and 15·5 per 1000 in the two preceding weeks, declined to 14·3 in the week ending June 6th. During the first ten weeks of the current quarter the annual death-rate in these eight towns averaged 17·1 per 1000, and exceeded by no less than 2·7 the mean rate during the same period in the 76 large English towns. Among the eight Scotch towns the death-rate during the week under notice ranged from 12·3 in Leith and 13·3 in Paisley to 16·0 in Greenock and 16·7 in Dundee. The 503 deaths in the eight towns (against 542 and 546 in the two preceding weeks) included 30 which were referred to the principal epidemic diseases, showing a further decline upon the low numbers returned in the two preceding weeks; of these 30 deaths, 10 resulted from whooping-cough, five from measles, five from diphtheria, five from diarrhœa, three from "fever," and two from scarlet fever, but not one from small-pox. These 30 deaths were equal to an annual rate of 0·9 per 1000, the mean rate from the same diseases in the 76 English towns during the same week being 1·1. The 10 deaths from whooping-cough showed a decrease compared with those in the two preceding weeks; five of these deaths were registered in Edinburgh and three in Dundee. The five fatal cases of measles were the lowest in any week during the present year; four were returned in Glasgow and one in Edinburgh. The five deaths from diphtheria, equal to the number returned last week, belonged to Glasgow. The five deaths from diarrhœa were considerably below the average; two cases were registered in Dundee. Of the two deaths from scarlet fever, one occurred in Glasgow and one in Paisley. One death from enteric fever was registered in Edinburgh, and one from enteric fever and one from cerebro-spinal meningitis in Glasgow.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 22·2 and 15·9 per 1000 in the two preceding weeks, rose to 16·5 in the week ending June 6th, and with the exception of last week was lower than in any previous week of this year. During the first ten weeks of the current quarter the death-rate in Dublin averaged 21·3 per 1000; the mean rate during the same period did not exceed 14·0 in London and 15·8 in Edinburgh. The 125 deaths of Dublin residents registered during the week under notice showed an increase of five over the number returned in the previous week, and included nine which were referred to the principal epidemic diseases, against four and six in the two preceding weeks. These nine deaths were equal to an annual rate of 1·2 per 1000, the rate during the week from the same causes being 0·9 in London and 1·2 in Edinburgh. Of the nine deaths from these epidemic diseases in Dublin, three resulted from measles, two from diphtheria, and one from scarlet fever, one from whooping-cough, one from "fever," and one from diarrhœa, but not one from small-pox. The 125 deaths from all causes in the city during the week under notice included 26 of infants under one year of age and 28 of persons aged upwards of 60 years, the deaths of elderly persons being considerably fewer than in any previous week of this year. Four inquest cases and two deaths from violence were registered, and 61, or 48·8 per cent., of the deaths occurred in public institutions. The causes of all but four of the deaths during the week were duly certified. The causes of all but three of the 1068 deaths in London were also duly certified, but more than 5 per cent. of the causes of death in Edinburgh were uncertified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Inspector-General of Hospitals and Fleets William Edward Breton has been placed on the Retired List at his own request (dated May 30th, 1908); and Surgeon Alexander Cameron Renwick has been allowed to withdraw from His Majesty's Naval Service with a gratuity (dated June 4th, 1908).

In accordance with the provisions of His Majesty's Order in Council of August 11th, 1903, Surgeon John Shipsey has been allowed to withdraw from the Royal Navy with a gratuity.

The following appointments are notified:—Surgeons: P. D. Ramsay to Gibraltar Hospital and Aloysius F. Fleming to the *Vivid* for Royal Naval Barracks.

ARMY MEDICAL SERVICE.

Surgeon-General Richard H. Quill is placed on retired pay (dated June 8th, 1908).

DEATHS IN THE SERVICES.

Surgeon-General Sir James Arthur Hanbury, A.M.S., K.C.B., on June 3rd at Bournemouth in his 77th year. He entered the service in 1853 as assistant-surgeon, was made surgeon in 1863, surgeon-major in 1873, deputy-surgeon-general in 1881, and surgeon-general in 1887. He retired in 1892. He served in the Afghan war of 1878–80, and took part with the expedition into the Bazar Valley (mentioned in despatches), accompanied Sir Frederick Roberts in the march to Candahar, and was present at the battle of Candahar (mentioned in despatches, C.B., medal with clasp, and bronze decoration). Served in the Egyptian war of 1882 as principal medical officer, and was present at the battle of Tel-el-Kebir (twice mentioned in despatches, K.C.B., medal with clasp, 2nd class of the Medjidieh, and Khedive's Star).

THE BRITISH RED CROSS SOCIETY.

Notice is given in the *London Gazette* that a petition of Her Majesty the Queen and the Right Honourable Lord Rothschild, G.C.V.O., praying for the grant of a Charter for the incorporation of the British Red Cross Society, has been presented to His Majesty in Council; and His Majesty having referred the petition to a committee of the Lords of the Council, further notice is given that all petitions for or against such grant should be sent to the Privy Council Office on or before the sixth day of July, 1908.

NAVAL VICTUALLING.

The *Times* of June 9th in an article from a correspondent states that: "The victualling and canteen arrangements introduced into the navy on October 1st last have, after six months' working, proved an unqualified success as far as the men are concerned, and it is claimed that they will save no less than £500,000 on the first year's working. ...... Those who took a leading part in bringing about these reforms hoped that not only would a saving be effected for the men of the navy but also for the State; so far this latter hope has met with disappointment. ...... There is, however, a more unsatisfactory feature from the national point of view. Tea, which is admittedly of very fine quality, can be purchased for 1*s.* per pound, sugar at 2*d.*, and fresh meat at 4*d.*; this is creating an unhealthy market for these articles at the home ports, and though there

LYNN THOMAS AND SKYRME FUND.

THE following subscriptions have been received between May 29th and June 5th by Mr. William Sheen, M.S. Lond., F.R.C.S. Eng. (2, St. Andrew's-crescent, Cardiff), honorary secretary to the fund.

Subscribers of Seventeen Pounds Thirteen Shillings and Sixpence.

Westminster Division of the British Medical Association, per Harvey Hilliard. (Full list of names will be published next week.)

Subscribers of Ten Guineas.

Clinical Society of Manchester, per Gordon Fitzgerald.

Subscriber of Five Pounds.

Anonymous.

Subscribers of Four Pounds Twelve Shillings.

Blackburn Division of the British Medical Association, per Howard Henry, the amount being made up as follows:—

Half-a-Guinea from—

J. T. Ballantyne.
M. Bannister.
E. D. S. Heyliger.
F. W. Taylor.

Ten Shillings from—

John Barr
William Moir

Five Shillings from—

Dr. Arnold.
Andrew Baxter.
Dr. Geddie.
Howard Henry.
T. T. Maclin.

Half-a-crown from—

J. W. Miller.
E. M. Payne.

Subscribers of Four Pounds Five Shillings.

Wigan Medical Society, from some of the Members, per John Blair.

Subscribers of Three Pounds Three Shillings and Sixpence.

Portsmouth District of Southern Branch of the British Medical Association, per B. H. Mumby.

Subscriber of Two Guineas.

John W. Stephens, Cardigan.

Subscribers of One and a Half Guineas.

Wolverhampton Branch of the British Medical Association, per J. Alfred Codd, being half a guinea each from the following—

Anon.
J. T. Harthill.
H. Malet.

Subscribers of One Guinea.

Thomas Baker, Waterlooville, Cosham, Hants.
R. A. Cowie, Ebbw Vale, Mon.
Mark Jackson, Purley.
Edgar Haydon, Newton Abbot.
G. W. Homan and F. W. Rowland, Lichfield.
James Hussey, Farnham, Surrey.
E. R. Williams, Carmarthen.
S. Wallace, Cardiff.

Subscriber of Half-a-Guinea.

W. Macphail, Coatbridge, N.B.

Subscriber of Ten Shillings.

John Jones, Dolgelly.

Subscriber of Five Shillings.

William Cash Reed, Liverpool.

Subscriber of Half-a-Crown.

A Friend.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

THE annual general meeting of this society was held on May 14th at 11, Chandos-street, Cavendish-square, Dr. G. FIELDING BLANDFORD being in the chair. Seven directors were elected to fill the vacancies in the court. A cordial vote of thanks was passed to the editors of the medical journals who from time to time publish notices of the society.

The report for 1907, which was adopted, stated that during the past year 11 new members were elected and ten died. The society consists at the present time of one honorary member, 144 life, and 144 paying members, making a total of 289, which, considering the number of medical men who are eligible for membership, is but a very small proportion. The invested funds amount to £99,260, from which is derived in interest the sum of £3118 2s. 5d.; £433 0s. 3d. were received in subscriptions and donations. Amongst the annuitants of the charity—namely, 49 widows and 17 orphans—the sum of £3151 10s. was distributed. 43 widows received £50 each, four £40, one £30, and one £25 with £10 extra at Christmas, and each orphan £12 and £3 extra at Christmas.

The Copeland Fund is a special fund which enables the society to grant to any widow or orphan already in receipt of the society's ordinary relief, extraordinary relief in special circumstances of unusual distress such as blindness, paralysis, insanity, severe disabling accident, or grave permanent disease, and to continue such extra relief in the case of orphans beyond the age of 16 or 18 years (at which, under the society's existing by-laws, the ordinary relief ceases) for such further period as the court of directors may think fit.

During the year two widows in receipt of grants died. One, whose husband had paid in subscriptions £26 3s., had received £490, and the other, whose husband had paid in annual subscriptions £27 6s., had received £2324: she had been in receipt of grants since 1866. Two widows were elected during the year, and on Dec. 31st there were 48 widows and 16 orphans in receipt of grants. One of the widows has been on the books since 1854 and has already received over £2060. Relief is only granted to the widows and orphans of deceased members who have paid their annual subscription for three years or who are life members. During the year nearly 50 letters were received from widows of medical men, who, in many instances, had been left practically penniless, asking for relief, but this had to be refused as their husbands had not been members of the society.

The directors cannot too strongly urge upon the members of the medical profession, especially the younger ones, the desirability of joining the society. Membership is open to any registered practitioner who at the time of his election is resident within a 20-mile radius from Charing Cross. Should any member remove beyond the limits of the society he nevertheless continues to be a member.

The annual subscription is 2 guineas; every member who has paid this sum for 25 years becomes a member for life. Life membership may also be obtained by the payment of one sum, varying with the age of the applicant. Further particulars and application forms may be obtained from the secretary at the offices of the society, 11, Chandos-street, Cavendish-square, London, W.

The meeting closed with a vote of thanks to the chairman.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8731 births and 3958 deaths were registered during the week ending June 6th. The annual rate of mortality in these towns, which had declined in the four preceding weeks from 14·2 to 12·6 per 1000, rose slightly to 12·7 in the week under notice. During the first ten weeks of the current quarter the annual death-rate in these towns averaged only 14·4 per 1000, and in London during the same period it did not exceed 14·0. The lowest annual death-rates in the 76 towns during the week under notice were 6·4 in Walsall, 6·9 in Handsworth (Staffs), 7·4 in Aston Manor, 7·9 in Bury, 8·5 in Tynemouth, 8·9 in Reading, and 9·0 in Hornsey; the rates in the other towns ranged upwards to 17·4 in Grimsby, 17·7 in Stockton-on-Tees, 19·4 in Stockport, 19·9 in Hanley, 20·9 in Merthyr Tydfil, and 24·5 in Swansea. The death-rate in London during the week did not exceed 11·6. The 3958 deaths in the 76 towns during the week showed a further decline of 185 from the numbers returned in the four preceding weeks, and included but 354 which were referred to the principal epidemic diseases, against numbers declining from 445 during the nine preceding weeks; of these 354 deaths, 103 resulted from whooping-cough, 83 from measles, 67 from diarrhœa, 45 from diphtheria, 33 from scarlet fever, and 23 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases last week were equal to an annual rate of 1·1 per 1000, against 1·2 per 1000 during the nine preceding weeks; the rate from these diseases in London did not exceed 0·9 per 1000. No death from any of these epidemic diseases was registered last week in Willesden, Walsall, Huddersfield, St. Helen's, or in nine other smaller towns; the annual death-rates from these diseases ranged upwards, however, to 2·6 in Reading, 2·7 in Preston, 3·4 in Norwich and in Merthyr Tydfil, and 3·9 in Stockton-on-Tees. The fatal cases of whooping-cough in the 76 towns, which had been 114 and 75 in the two preceding weeks, rose to 103 last week; this disease caused the highest death-rates, 1·5 in Smethwick and in Burnley, 1·7 in Barrow-in-Furness, and 2·2 in Warrington. The deaths from measles, which had been 100 and 72 in the two preceding weeks, rose to 83 in the week under notice, the highest rates being 1·3 in Preston, 1·6 in Rhondda, and 2·9 in Stockton-on-Tees. The 67 deaths from diarrhœa was the highest weekly number this surgeon, and unfortunately died a short time after an operation performed to relieve a necessarily fatal disease. The operator attended and after giving evidence expressed his surprise that an inquest had been held on the case; but Mr. Troutbeck is reported to have said: "That it was the opinion of all coroners in England that if an operation was a material part of the cause of death an inquest must be held," and he further stated that "it was impossible to dissociate the operation entirely from this woman's death." What is meant exactly by "a material part of the cause of death" might furnish matter for a very nice argument, but it would be interesting to know if all the coroners in England agree with Mr. Troutbeck in his sweeping definition that it is a material part of the cause of death when it cannot be dissociated from the cause of death. If they do, it is perhaps fortunate for the public that they do not act up to their opinion.

In nearly all cases where deaths follow after operations it would be impossible to dissociate the operation entirely from the cause of death, so that it would practically mean the holding of an inquest on every death after an operation. If such a course were adopted it would be a fatal bar to all progressive surgery, and it is shocking to contemplate the probable effect it would have in increasing the sum of human misery. Few operations would be performed where any risk was involved, and palliative operations would rarely, if ever, be done. Great enough in all conscience is he worry and anxiety that every surgeon has to undergo after a serious operation, and to have superadded to it the knowledge that if the result is unfortunate he will be required to justify all the details of the operation before a dozen gnorant jurors, presided over by a coroner possibly in this respect equally ignorant, is a prospect that few surgeons could view with equanimity.

I am, Sir, yours faithfully,
MAJOR GREENWOOD, M.D. Brux., LL.B.,
Barrister-at-Law.
June 5th, 1908.

THE GRAND DUCAL HESSIAN STATE AND THE ST. GEORGE'S-NAUHEIM INSTITUTE.

To the Editor of THE LANCET.

SIR,—There have recently appeared in the lay press notices relating to an injunction which was by consent granted against this institute at the suit of the Hessian Government. As such notices in their abbreviated form and in the absence of an explanation are calculated to cause an entirely erroneous impression regarding an institution of which, in conjunction with my colleague, Mr. W. de Marchot Hill, I am in charge, I ask of your courtesy to insert this letter in your widely read paper. This institute has been under my control for the past few months, and whilst disclaiming any responsibility for the action of the directors before my connexion with the institute I feel that it is due to my colleague, myself, and those of my profession who have so cordially supported me that an explanation of the very misleading paragraphs that have appeared in the leading daily journals should be given. The injunction was, *inter alia*, to restrain the St. George's-Nauheim Institute from representing that they were the agents of the Hessian Government, from using the Hessian arms, from representing their business as a branch of the Government, and from using the name Nauheim without clearly distinguishing the baths of the institute from those of the Government.

From the fact that the injunction was consented to it might be inferred that the St. George's Institute had wrongfully committed all these acts, but as a matter of fact Mr. Cosens Hardy, who represented this institute at the trial, particularly repudiated such a state of affairs and agreed to the injunction because it necessitated absolutely no change in any detail whatsoever in the present conduct of the institute. Mr. McNaughton, K.C., on behalf of the Hessian Government, stated that the directors of the St. George's Institute had claimed that the Nauheim system can cure every malady that flesh is heir to. Although in no way connected with, or responsible for, the statements referred to, I should like to point out that the list of ailments published by the directors of the institute is identical with that published by the Society of Physicians at Bad Nauheim in their prospectus, so that it would appear that the Hessian authorities are complaining of the act of their own Society of Physicians.

Personally, I think most medical men will agree with me in supporting the Hessian Government in their condemnation of this extraordinarily prolific list of diseases. At all events, since taking charge of the institute I have very much curtailed the list of indications. As for many months past the institution has been conducted on methods above reproach and approved by many of the leading physicians and medical journals, this short explanation will suffice to remove any doubts that may have been raised by the reports in the lay press. Trusting that I have not encroached too much on your patience and space,

I am, Sir, yours faithfully,
W. BAIN, M.B., B S. Lond.
George-street, Hanover-square, London, W., May 28th, 1908.

TANSINI METHOD FOR THE CURE OF CANCER OF THE BREAST.

To the Editor of THE LANCET.

SIR,—I have read in THE LANCET of March 28th a critical letter from Mr. W. Sampson Handley about the Tansini method for the cure of cancer of the breast. I do not understand the allusion to the deep band, as by Tansini's method it can be removed more easily than by any other method without extensive dissection, which is to be avoided both from the point of view of the patient and of the technical excellence of the operation. Perhaps on account of the shortness of my note I did not insist sufficiently on what is, for the most part, well known, that even with more radical methods recurrence in the skin is often observed in the immediate neighbourhood of the scar. I have often observed a recurrence in the skin when by the ordinary methods it has not been removed freely enough owing to anxiety to obtain direct union of the wound. It is necessary to remove as much skin as possible; it is especially on this account that Professor Tansini devised his plastic operation, and he was not alone in thinking it necessary to have recourse to such a measure as a remedy for the removal of the skin. Others have proposed to obtain the flap from the skin near the wound left by the operation or to fill this up by transplanting the breast of the opposite side. Professor Tansini has devised a very rational plastic procedure which offers other advantages which I have already mentioned. All surgeons recognise the necessity of extensive removal of the skin and we cannot affirm that it is possible to join the flaps direct if all the skin of the breast has been cut away. If it be objected that the cutting of the flap makes the operation a little more complicated it must be borne in mind that in any case the operation is a very serious one, that relapses are frequent, that as a rule, at least in Italy, patients come to be operated on with the disease advanced, and that the statistics have improved since extensive removal of the skin has been performed. Unless this principle, which is now generally accepted, be abandoned I must persist in recommending the Tansini method as one worthy of being widely known and employed.

I am, Sir, yours faithfully,
Prof. FRANCESCO PURPURA.
Pavia, June 1st, 1908.

THE ADMINISTRATION OF VACCINES BY THE MOUTH.

To the Editor of THE LANCET.

SIR,—Dr. Olive Riviere, in THE LANCET of June 6th, states that it is impossible to prove that tuberculin and other vaccines are absorbed when administered by the mouth in a disease such as pulmonary tuberculosis, as he holds that "in this disease auto-inoculation is continually going on and the opsonic index is continually fluctuating." He therefore asks for proof of absorption in cases of localised disease with a stationary index. I do not agree with his argument or with his conclusion, but gladly supply the proof he requires. Chart 31 (showing indices of 1·3 and 1·4) *in the paper*[1] referred to by Dr. Riviere is an example of the effect of the oral administration of tuberculin in a case of localised infection of glands in which the index had been 0·6 or 0·7 for several days before tuberculin was prescribed. *Chart* 15 is an example of the absorption of staphylococcic vaccine when given by the mouth. In this instance the index fell from may be *no loss to* the Government on the sale of the two former articles the traffic is vicious and will tend to grow unless checked. On meat, however, there must be a loss, as from market quotations the Admiralty *must* be paying from 6*d*. to 7*d*. per pound for it; to retail it at 4*d*. per pound with permission to take it on shore seems to be a mistake. This privilege of taking meat on shore is a very old one and few would like to see it stopped in the case of married men who really require it for their own consumption, but the privilege was never intended to extend into a traffic."

---

[1] Proceedings of the Royal Society of Medicine, Medical Section, vol. i., No. 6, p. 195, April, 1908.

Surgeon-General W. Simson Pratt, C.B., A.M.S., principal medical officer, Southern Command, made his annual inspection of the Devonport Military Hospital and Military Families Hospital on June 2nd. He was accompanied by Lieutenant-Colonel H. G. Hathaway, R.A.M.C., and Colonel W. J. Read Rainsford, C.I.E., R.A.M.C. Surgeon-General Pratt inspected Okehampton Camp (Devon) on June 4th.

Correspondence.

"Audi alteram partem."

AUSTRALIA FOR THE SONS OF PROFESSIONAL MEN.

To the Editor of THE LANCET.

SIR,—It is a good many years since I resided in Great Britain, but even then the problem of "what to do with our boys" pressed heavily upon the parents of the professional classes. The army and navy were closed to those who had no private income, the clerical, legal, medical, and other professions were overstocked, and the openings in commerce were only for those who had money or influential connexions. And everything that I can learn points to an intensification of these conditions at the present day. The position, therefore, of the man who has sons about to leave school must be a very difficult one, when he is face to face with the question of how to give them a satisfactory start in life. It is the hope of being able to do something to answer this question which prompts me to beg for some space in your columns.

For years, many of the sons of professional men have emigrated to the United States or Canada. I come forward with the claim that Australia and New Zealand can offer opportunities superior to either of these two countries to industrious and persevering lads, who are prepared to accept rough and strenuous conditions for the sake of obtaining a competence in later life. I may say at once that there are no openings in our large towns. All the city occupations are filled to overflowing. But the Australian bush is calling for thousands of willing hearts and hands to subdue it and make it fruitful. The wealth of Australia is immense and this is mostly due to the production of wool, wheat, sugar, butter, live stock, and fruit commodities, for which there is a great and growing demand, at prices that are likely to be maintained or increased. Life on the land therefore promises to him who approaches it in a spirit both scientific and practical the opportunity not only for a healthy and natural existence but the possibility of an independence. The glorious climate of Australia is all in its favour. Here there is no long rigorous winter. A man can work and stock graze in the fields all the year round. Much has been said about the Australian droughts, but it is not generally known that there are wide districts where drought is practically unheard of. And the conservation of fodder and the great irrigation schemes which are being carried out will henceforth rob the occasional droughts of much of their terror. In New South Wales there has been only one total failure of the wheat crops in 17 years.

I do not for a moment suggest that lads should be sent out here with some money to take up land for themselves straight away. This would simply spell disaster. What I propose is that the lad who has decided to make Australia his home should adopt one of three courses:—

1. He should enter as a student at one of the Government agricultural colleges, where, for about £30 a year, he will receive a thorough training in scientific and practical farming. The sum quoted includes board and lodging, both of which I can guarantee to be excellent—quite as good as, if not better than, that provided at any English public schools. At the end of his two years' course there he could take up land for himself or spend another year in gaining experience with a practical farmer before launching out for himself.

2. He could be placed, as far as New South Wales is concerned, with a farmer holding high qualifications as a teacher of agriculture, who for £12 a year and his labour would give him a training almost as good as that he could obtain at a college. I am again prepared to guarantee that any lads intrusted to this man would be properly looked after and instructed.

3. The third alternative is that he could go to a Government farm for three months and receive, free of cost, instruction in milking, ploughing, and the care of horses, pigs, &c. At the end of this time his services would be of sufficient value to enable him to be placed with a respectable farmer who would pay him about 10*s*. a week and his board, and would increase his wages gradually to 15*s*. or 20*s*. After an apprenticeship of this kind for a year or two he would be fitted to start on his own account.

These three avenues to the land are open to all and there exists a voluntary organisation here, the Immigration League of Australasia, whose chief object is to welcome new-comers and afford them advice and assistance. The executive committee are prepared to give information about Australia and New Zealand to all who write to them, to arrange for the placing of lads at agricultural colleges or farms, to act generally *in loco parentis* towards them, and to see that they are not taken advantage of in any way. The league numbers among its members some of the leading men of Australia, and their desire is to help in the development of the continent and retain the British emigrant under the flag of Empire.

We say, send your sons to us and we will insure them proper treatment and a fair start. We do not want *ne'er-do-wells* or failures. Experience proves that such do no better here than in the old country. But steady, industrious lads are bound to succeed here and in many cases their parents might be induced to follow them out here and prolong their lives in this incomparable climate. We invite parents to communicate with us at Bull's Chambers, Moore-street, Sydney, Australia, and we will give them full information and send books and maps about Australia and New Zealand and prospectuses of agricultural colleges and schools of mines. Some months' notice is needed to enable a lad to be entered at an agricultural college.

I am, Sir, yours faithfully,

RICHARD ARTHUR, M.D. Edin.,
President, Immigration League of Australasia.

*** It seems to us a grave reflection upon our politicians, all parties alike being referred to, that England, Ireland, and Scotland should offer no advantages, commensurate with those offered by Australia, New Zealand, and Canada, to those who wish to follow agriculture as a career. There are in all three divisions of the United Kingdom large tracts of land—only not regarded as large because of the inevitable comparison with the vast acreage of the colonies mentioned —which would repay farming, at any rate "intensive" farming, but which at present are almost out of cultivation, and these tracts are contiguous to thickly populated cities. That labour and produce are not forthcoming from them upon terms profitable alike to the public, the employer, and the employed is a standing indictment of our rulers. But the home conditions being what they are we can only commend Dr. Arthur's letter to the attention of any of our readers who have sons to bring up.—ED. L.

MR. CORONER TROUTBECK AND DEATHS AFTER OPERATIONS.

To the Editor of THE LANCET.

SIR,—The coroner's office is a very ancient one and has no doubt in its time done useful work in promoting the public welfare. None the less there are not wanting some among us who regard its survival as an anachronism, its machinery cumbrous and antiquated, and think that the public safety might be quite as efficiently protected in a simpler and less expensive manner. If all the coroners in England and Wales were to tread in the footsteps of Mr. Troutbeck it is not unlikely that the number of those holding such views would be much augmented. Last week an inquest was held in South-West London on Gertrude Helen Muirhead, a teacher of music, who was the patient of an eminent London

NOTES UPON HEALTH RESORTS.

SCANDINAVIAN WINTER HEALTH STATIONS.

(BY A SPECIAL COMMISSIONER.)

V.[1]

THE ANTI-TUBERCULOSIS MOVEMENT IN NORWAY AND PUBLIC SANATORIUMS FOR TUBERCULOUS CASES.

No study of Norwegian health stations can be counted satisfactory and complete which neglects to consider the influence and character of the anti-tuberculosis movement. Norway, in spite of its climatic and other advantages, has suffered much from both leprosy and tuberculosis. The former is now rapidly becoming extinct but the latter has until the last decade been steadily increasing.[2] The fact is, Norwegians have been slow to develop that "health conscience" and "hygienic mind" which are essential to the establishment and maintenance of rational and effective prophylactic measures against tuberculosis. Even still, as your Commissioner had abundant opportunities of noting, there is a conspicuous lack of observance of many of those procedures and precautions which experiment and experience have demonstrated to be essential for the successful conduct of an anti-tuberculosis campaign. Promiscuous spitting is prevalent everywhere. Spittoons are provided in nearly all public places but apparently are never or rarely supplied with disinfectants. Railway carriages generally possess open receptacles for sputum. Spittoons are prominent features in institutions of almost every kind. I was astonished to find a spittoon by the bedside of each patient in the leper hospital near Trondhjem. Scandinavians seem to have an innate propensity for indiscriminate expectoration. This is due no doubt in a measure to the catarrhal conditions induced by overheating of dwellings, excessive smoking, and in some instances chewing of tobacco. The old-fashioned homesteads are almost invariably dark and the arrangements for sleeping are still generally devoid of adequate hygienic requisites. Even in modern houses and public establishments of all kinds the temperature during winter is kept so high as to cause considerable discomfort to an ordinary Englishman.

Open-air methods are clearly not so popular in the Norwegian home as in our own country. Until comparatively recently little has been done to prevent the spread of tuberculous infection and even now the geographical and sociological conditions prevailing in Norway make adequate supervision and the conduct of sanitary reforms matters of considerable difficulty.

ANTI-TUBERCULOSIS MEASURES.

I had the privilege of discussing the anti-tuberculosis movement with Dr. M. Holmboe, the Norwegian State Medical Director at Christiania, Dr. Andvord, Dr. Sömme, and other well-known leaders, and of seeing something of the practical efforts which are now being vigorously carried on with the aim of stamping out this scourge of the people. Norwegian medical practitioners have for long recognised that just as leprosy has been almost exterminated by early recognition and segregation of cases, so tuberculosis will have to be dealt with by the wise application of legislative measures and a personal care of the afflicted patients.

Norway's advanced position in regard to its "tuberculosis laws" is due mainly to the energy and wisdom of its chief medical officers, Dr. M. Holmboe of Christiania and Dr. Klaus Hanssen of Bergen. Norway can justly claim to be the first country in the world to adopt legislative enactments for the compulsory notification of "open" tuberculous cases. Since the beginning of 1901 infectious tuberculous cases have been reported to the district medical officer. If the medical attendant's instructions are not complied with the sanitary authority is empowered to remove the patient to the hospital and necessary disinfection is carried out at the public expense. The salutary effects of legislative measures and educational efforts are now becoming manifest. During the three years 1902 to 1904 the mortality from pulmonary tuberculosis was 2·4 per 1000 inhabitants. In the last ten years the mortality has fallen more than 15 per cent., the most marked decrease being in the urban districts. In Bergen, where the influence of Dr. Klaus Hanssen is far-reaching, it is said that the mortality has decreased 50 per cent. in the course of the last 11 years. The death-rate varies greatly in the different districts or amts as they are called In Kristian amt during the years 1901–05 the mortality varied from 1·6 to 2·0 per 1000, while in Finmarken it was as high as 4·5 per 1000.

In interpreting the foregoing statistics it is necessary to bear in mind the influence of social and national movements. During recent years large numbers of the population have taken to town life and factory work. Agricultural pursuits are on the wane. There are now greater facilities for communication between districts and outlying hamlets are less isolated than formerly. A constant stream of emigration of the vigorous and young is going on to America, the sick and feeble being left behind. Many of those who have become victims of tuberculous disease in the United States and elsewhere are returned to their native land. As Dr. Holmboe has well pointed out, it is necessary not to overestimate or to exaggerate the value of the tuberculosis laws, for all too little time has elapsed to allow of a just estimation.[3]

A special committee of the Association of Norwegian Physicians has been formed, with Dr. Holmboe as chairman, to study the anti-tuberculosis measures in Norway and to direct the various forms of effort and enterprise available for the public good. This committee also seeks to link the campaign in Norway with the international movement which is now exercising world-wide influence.

The Norwegian Women's Sanitary Association, which was originally formed to provide for the injured in time of war and recently has done much to relieve the hard lot of the fisher-folk, has now taken up anti-tuberculosis work and such practical assistance promises to be invaluable. The judicious service of this organisation has in chief measure led to the establishment of "pleiehjems," on the introduction of which Norway may be congratulated. A "pleiehjem" is a nursing-home for advanced consumptive cases. These have been established in various districts of Norway and seem to meet admirably, and at comparatively small cost, the needs of a sparsely populated and far-extending country with limited means of communication.[4] "Pleiehjems" have now been established by eight or ten communes and by some five amts. In Christiania and Bergen special wards are provided for consumptives in the State hospitals. The nursing-homes for consumptives have proved a great boon to the country. They are usually small and homely with, as a rule, only from six to ten beds. A trained nurse acts as superintendent and the medical man of the district serves as medical attendant. The initial cost averages about £50 a bed and the expense of maintenance is comparatively small. These homes were primarily intended for the nursing of "open" and advanced cases of pulmonary tuberculosis likely to be dangerous sources of infection. About 300 beds are now available in these institutions. The "pleiehjem" is certainly a Norwegian institution which might well be adopted by other countries and for certain parts of the British Isles and its colonies should be very suitable. If instead of burying funds in stones and marbles and other needless extravagances some such country homes could be established in this land for cases which the ordinary sanatorium cannot or will not take, a great step would have been taken towards the arrest of tuberculosis among our people.

Norwegian physicians and statesmen, through their experience with leprosy—a disease in many ways akin to tuberculosis—are peculiarly well fitted to approach the practical conduct of the anti-tuberculosis movement without undue pessimism and devoid of extravagant and irrational hopes. Their reasonable legislative measures, rational philanthropic endeavours, and practical methods in dealing with tuberculosis all merit high praise and are worthy of serious study.

Portland-place, W., June 9th, 1908. ARTHUR LATHAM.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—A friend of mine who is a dentist has drawn my attention to a pamphlet entitled "The Contemplated Medical Anæsthetists Bill." It is signed by Mr. Robert Marston. In this it is implied that I am to give a demonstration concerned with chloroform for a stake of £5 a side! It appears a grotesque assumption that I should lend myself to such a proceeding, but as the pamphlet has been scattered broadcast I am compelled to say that my name has been used without my permission, and I have no intention of countenancing any demonstration of the kind. I shall be obliged to you for giving publicity to this statement.

I am, Sir, yours faithfully,

Mortimer-street, W., June 9th, 1908. DUDLEY W. BUXTON.

"THE OLDEST INSTITUTION FOR TREATING SICK CHILDREN."

To the Editor of THE LANCET.

SIR,—To prevent misconception such as has occasionally arisen in the past and which might arise again in the future from the recent letter to the papers from the secretary of the Royal Waterloo Hospital, may I ask you to state that the first hospital for sick children to be established in this country was the Hospital for Sick Children, Great Ormond-street. The treatment which the Royal Waterloo Hospital afforded before 1852, the year of the foundation of the Great Ormond-street Hospital, and for many years after that date, was dispensary treatment only. How great was the need of a children's hospital at that time may be gathered from the fact that in January, 1842, out of 2363 persons in all the London hospitals only 26 were children under the age of ten, while of 50,000 person dying annually in the metropolis 21,000 were children under that age.

I am, Sir, yours faithfully,

STEWART JOHNSON, Secretary.

Hospital for Sick Children, Great Ormond-street,
London, W.C., June 9th, 1908.

THE MEDICAL DEFENCE UNION.

To the Editor of THE LANCET.

SIR,—At the annual meeting of the Union at Liverpool on May 21st and reported in your issue of the 30th, the chairman is reported as saying—

> It was suggested that some scheme could be adopted by which the whole risk of adverse verdicts and damages should be taken over, but after serious consideration it was decided that it was not possible, and further that it would be against public and professional polity and likely to lead to serious injury to the profession if not to actions for champerty and maintenance.

Now, as one who has been long of opinion that such a scheme is most desirable, could one be devised which was workable, I am naturally disappointed at the result of the deliberations of the Council, but of course find no fault with their decision, which no doubt has been come to for reasons which to them seem sufficient; but what I think many members will not appreciate is how "serious injury to the profession" is likely to result from such a scheme, or how actions for "champerty" and "maintenance" could follow.

I can quite understand that where an insurance company came in as undertaking to indemnify the Union there might be difficulties in arranging as to the conduct of the defence of an action against a member, and I also quite understand how to the company the vindication of the member's professional reputation would weigh as nothing against a prompt and easy settlement by compromise, but surely such a difficulty could be met by the Union itself instituting a scheme of mutual indemnity insurance amongst its members, a much more business-like and dignified mode of making provision against evil fortune than the usual appeal on behalf of the unfortunate one who finds himself at the end of his plaint, whether the result be favourable or unfavourable to him, face to face with very heavy, in some cases ruinous, costs. The machinery seems to me already to exist in the Union's organisation and I do not think it would beat human wit to adapt it to such a further use.

But what about this exposing the member to the charge of "champerty and maintenance"? Not being a member of the sister profession of law I can have no valid opinion of my own, but from anything I can find readily on the subject I fail to see the ground for such an opinion and how such an action could lie.

Champerty is thus defined: "A combination for an evil purpose—a bargain, either with the plaintiff or defendant, to contribute towards the costs of litigation, the price being a share in the spoil"; and the Oxford English Dictionary gives the following:—"*Champerty*, or more correctly *Champarty*: The alleged proceeding whereby a party, not naturally concerned in a suit, engages to help the plaintiff or defendant to prosecute it, on condition that if it be brought to a successful issue, he is to receive a share of the property in dispute" (Vol. II., C.); and "*Maintenance*: The action of wrongfully aiding and abetting litigation; sustentation of a suit or suitor at law by a party who has no interest in the proceedings or who acts from any improper motive," and under the same rubric Sir F. Pollock is thus quoted: "The wrong of maintenance or aiding a party in litigation without either interest in the suit, or lawful cause of kindred, affection or charity for aiding him: is akin to malicious prosecution and other abuses of legal process ...... actions for maintenance are in modern times rare though possible" (Vol. VI., M).

Again, in the Dictionary of English Law, by Charles Sweet, the following occurs: "*Champarty* or *Champerty* is the act of assisting the plaintiff in a legal proceeding, in which the person giving the assistance has no valuable interest, on an agreement that if the proceeding is successful the proceeds shall be divided between the plaintiff and the assisting person"; and "*Maintenance* ...... in the courts includes Champarty and Embracery, and is also used generally to denote the offence committed by a person, who, having no interest in a suit, maintains or supports either party with money or otherwise to prosecute defendant."

Now if the above quotations are to be taken as an at all correct interpretation of the meaning of such acts they might certainly be used as arguments against the intervention of the Union in any suit either undertaken or defended by a member, but I fail to see how they can be used solely as an argument against the Union embarking in any scheme of indemnification of the kind spoken of. If the Union cannot extend its operations in this direction then it seems to me we must try if we can get some of the insurance companies doing this class of business to extend their operations so as to cover medical men just as chemists and dentists are already covered.

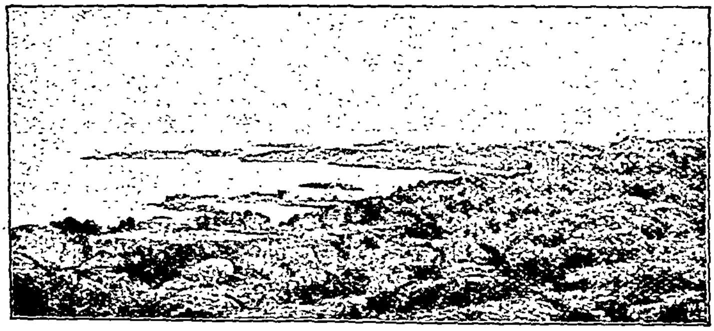
I am, Sir, yours faithfully,

June 1st, 1908. A MEMBER.

THE NATIONAL HEALTH SOCIETY.—The Lord Chief Justice presided last week at Grosvenor House over the thirty-fifth annual meeting of the National Health Society. After the presentation of diplomas to a number of the society's successful students by the Dowager Duchess of Westminster, Lord Alverstone commented on the change which had come over public opinion since the society's formation, for in the past year there had been a great demand for trained and qualified women. Medical men had pointed out the hopeless ignorance of many poor mothers as to the feeding and bringing up of young children and he had had extraordinary evidence of this in cases brought before him as a judge. The work of health visitors was therefore greatly needed. He moved: "That the National Health Society is deserving of all support, a more general and thorough knowledge of hygienic principles as applicable to home life being absolutely essential to the welfare of the community" The Archdeacon of London, in seconding, commended the society for constantly revising its publications and so making them reflect the light of fresh medical knowledge. Professor G. Sims Woodhead said that the profession was more and more engaged in "prevention rather than cure," and that before the elements of hygienic knowledge became known to all people had managed to live but they did not live so long. If as much time and money were devoted to prevention as to cure many of our hospitals might be shut and there would be plenty of funds available for those that remained. The motion was supported by Dr. E. B. Forman and Dr. H. R. Kenwood, and was adopted.

but of such I understand there are only a few, and they are granted no additional privileges or special consideration. The sanatorium receives no philanthropic support and has no legacies. Possibly in the future additional leper funds may be rendered available for its assistance. I was favoured with copies of the annual reports since 1903, exceedingly well arranged and reflecting great credit on the medical director and his staff. A report embodying the results of the first five years is in preparation. It speaks volumes that of the 1030 patients who have been under treatment all have been followed up except four. At Bergen there exist an after-care committee and a polyclinic on anti-tuberculosis dispensary lines which supervise all cases coming from that town and district. It is well to note that systematised work has for long been very successfully employed as a therapeutic agent on lines very similar to those in use at Frimley and elsewhere in this country. Many patients are employed in the construction of paths of various gradients. During the past five years the male patients have made wide paths for a distance of something like 4·3 kilometres. In the winter snow work and wood-chopping engage much time and attention. The women during the summer assist in the care of the paths and the grounds and engage in gardening. During the winter a number of patients are allowed to walk on skis for one and a half hours after breakfast.

FIG. 3.



View from the grounds adjoining the Fredriksværn Hospital for Tuberculous Children.

Dr. Emil Grundt, the medical director, to whom your Commissioner is indebted for much information, states in regard to this important subject of work for the consumptive that during the last five years about 30 per cent. of his patients have been able to engage in work and without any ill-effects having been noted. The cases are, of course, carefully selected. The temperature taken in the rectum is considered the safest guide. If the temperature after work is raised to 38·2° C. or 38·3°, no notice is taken of it provided that after ten minutes it has fallen to 37·8°. The work of this premier public sanatorium of Norway is so excellent that all Norwegians may well be proud of it and should accord to it all the support which it needs as well as deserves.

Reknæs Sanatorium.

This institution, situated near Molde on the northern shores of the Molde Fjord, is a converted leper hospital. It consists of a wooden structure of two storeys, with a central portion and two wings, inclosing a courtyard. The wards are small, accommodating from two to four patients in each. Consumptives of both sexes are received and usually a few beds are reserved for children. The difficulty of access to this sanatorium during winter months prevented your Commissioner visiting it.

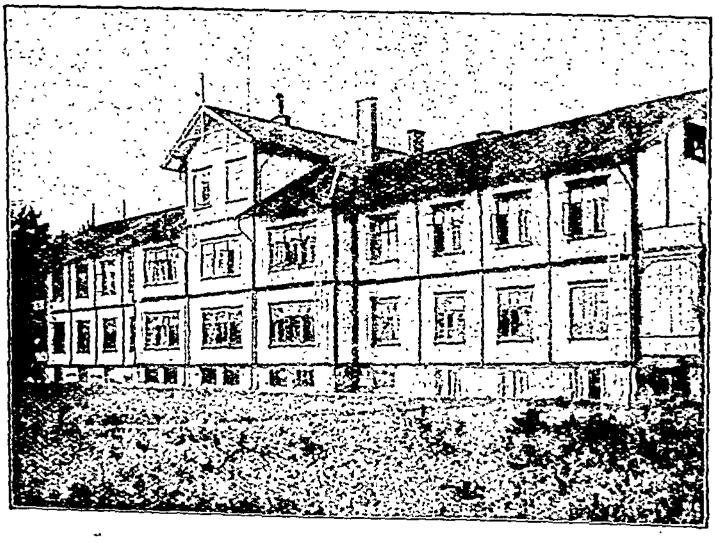
THE CARE OF TUBERCULOUS CHILDREN.

Norway has shown true wisdom in providing for its tuberculous children, and there can be but little doubt that by an extension of means for dealing adequately with tuberculously disposed young subjects lies the best hope for the future. The educational system in Norway is so excellent that there should be but little difficulty in recognising cases in early stages of the disease. By promptly dealing with such, and also by the development of greater domestic hygiene and the separation of children from intimate contact with "open" tuberculous adults, Norway will accomplish much for its "coming race."

The Fredriksværn Hospital for Tuberculous Children.

This is the first seaside sanatorium for tuberculous children established in Norway. It was founded as far back as 1892 by a board, the president of which was the late Queen Sophia, with funds provided by the Royal family, numerous private donors, and the "Samlag" of Christiania. It affords treatment for cases between 4 and 15 years of age. Sufferers from pulmonary tuberculosis are not admitted. The hospital is situated two kilometres distance from Fredriksværn, a picturesque and charmingly situated seaside resort near the mouth of the Christiania Fjord (Fig. 3). Larvik, about three miles distant, which can be reached by either road or boat, is its nearest railway town. The climatic conditions are those of a mild marine station. Experience shows that it possesses no special advantages over a more elevated inland station. Still, the position is convenient of access and its close proximity to the shore offers many attractions for the children. The hospital consists of a wooden main building of two storeys with accommodation for 100 cases, an isolation block, and necessary out-buildings. It also possesses electric and disinfection equipments. The wards are large, well lighted, and airy, and there are commodious day rooms. There are a satisfactory operating theatre and convenient laboratory (Fig. 4).

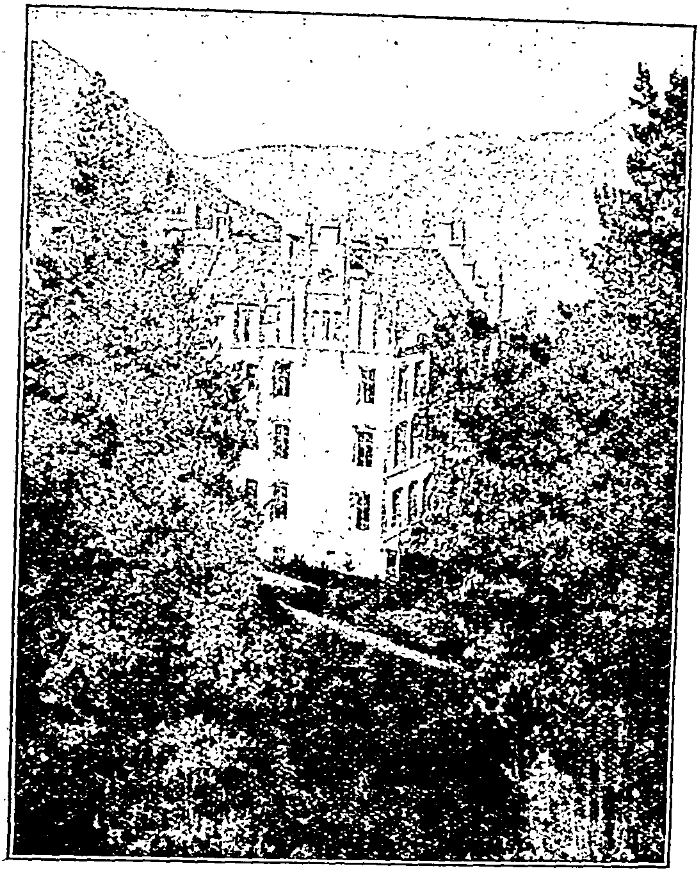
FIG. 4.



The Fredriksværn Hospital for Tuberculous Children. South aspect overlooking the Christiania Fjord.

The complete cost of the institution amounted to about kr 200 000. or kr. 2000 per bed—that is, a little more than £108 a bed. The working expenses amount to something like kr. 1 50 for each patient per day. The parents or friends of the little sufferers only have to contribute kr. 1.00 a day,

FIG. 1.



Lyster Sanatorium, showing its elevated position on the mountain side above the Sogne Fjord.

PUBLIC NORWEGIAN SANATORIUMS FOR CONSUMPTIVES.

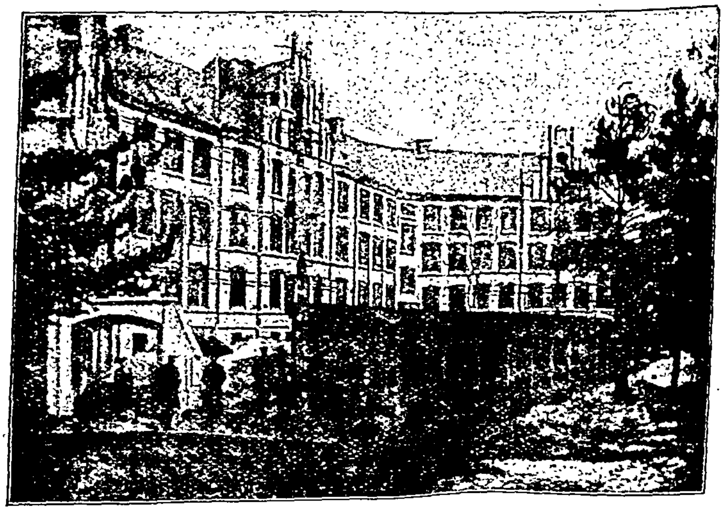
At present Norway possesses all too few public or State institutions for the adequate treatment of early necessitous consumptives. Funds which have been accumulating since the Middle Ages, originally provided for the support and treatment of lepers, are now being devoted to the care of consumptives, and as the number of lepers is steadily declining it seems likely that before long a still larger amount will be available for the establishment of sanatoriums or at all events the control of tuberculous patients. The old leper institution at Reknæs has been converted into an establishment for consumptives and funds originally intended for lepers have helped to build the new sanatorium at Lyster.

Lyster Sanatorium.

This representative institution is thoroughly modern, having been opened as recently as November, 1902. It is situated in the western part of Norway, on the southern slope of the mountain range bordering the Sogne Fjord. In winter it is very difficult of access and one cannot help thinking that it would have been wiser to select a less isolated district. It has been built out of the funds of the ancient St. Jörgen's Leper Hospital of Bergen, and owes its origin to the thought and enterprise of Dr. Klaus Hanssen, the senior physician of the Bergen Hospital. The sanatorium is excellently placed at an altitude of 470 metres above sea level in a peculiarly charming mountainous district (Fig. 1). The climate is sub-Alpine in character. During winter the whole country is snow-clad and frost-bound. At considerable expense a mountain road and wire tramway have been constructed from the lower level to the sanatorium. The institution consists of a main building, four summer houses, an isolation house, stables, and necessary offices and outhouses. Accommodation has been provided for 126 beds and in addition there is room for 12 patients in the summer pavilions. There are 18 bedrooms, originally designed for four patients in each, and allowing about 36 cubic metres per bed. Frequently five cases are placed in each room, the space allowance then being from 29 to 30 cubic metres per patient. There are also three bedrooms for four patients each. Twelve rooms are provided for single cases, but some of these are sufficiently roomy to take two patients. All the bedrooms face south. Separate dining and day rooms are provided for men and women. Good sanitary accommodation is provided for each sex on every storey and in the basement. In the main building are quarters for the medical director, rooms and offices for the resident staff, medical and administrative, and a laboratory. Heating is arranged for by means of a low pressure steam system. Hot and cold water are available throughout. Ample water-supply is provided for lavatories, baths, water-closets, and fire mains. There are modern appliances for steam cooking, electric lighting and ventilation, and an electrically heated disinfector for the sterilisation of sputum. The electrically driven system of ventilation has not been required as free natural ventilation can be secured both during summer and winter by means of open windows. Sewage is dealt with in a septic tank. A plentiful supply of spring water has been brought from the mountains in pipes and is so abundant that it also serves to drive the electric plant which works the tram and provides the lighting. A liegehalle is placed on the south side of the building. The grounds are extensive and adjoin the natural forest region (Fig. 2).

The isolated and elevated situation of the sanatoriums has added much to the initial cost and of course increases the expense of maintenance. The total cost has averaged something like kr. 5960, or about £322 per bed, an expenditure which compared with some similar institutions outside Norway must be considered very reasonable. The total working expenses for each patient are said to be kr. 2.95, or about 3*s*. per day, of which the State contributes kr. 1.75, or about 2*s*., and the patient or his friends contribute kr. 1.20 per day. Those, however, who are able pay kr. 2.95 per day

FIG. 2.



Lyster Sanatorium. South aspect with open-air shelter.

to this comparison because on page 6 of the report it is stated: "For even if it be conceded that the Irish official estimate is too low there can be very little doubt that an estimate calculated according to the British method is in the particular instance (i.e., Belfast) too high." Further, the return of new buildings erected in Belfast year by year shows that the last intercensal increase has not been maintained since 1901. In 1906, according to the report, the number of new buildings in Belfast fell to 622, which is lower than that for any previous year since 1850. Finally, calculations based on the birth-rate also point to a diminution of the rate of increase of the population. Keeping in mind all these facts, it seems an altogether doubtful, if not fallacious, hypothesis that in comparing the death-rate of Belfast with that of an English city we must first increase the population of Belfast by 31,000 over the number estimated by the accredited Irish authority, the Registrar-General. Such facts render more and more problematical the conclusion of the Commission that "it cannot be maintained that the death-rate of Belfast is, or that it has been in recent years, excessive, as has been alleged, when compared with those of other large cities of the United Kingdom." It is more than likely that in 1911 it will be seen that the estimates now made by Sir Robert Matheson, the Irish Registrar-General, will be nearest the exact facts. The Commission rightly considers it desirable that the whole question of the methods of framing these estimates should be carefully reconsidered by the Registrars-General for the three divisions of the United Kingdom, and that as it is so plainly of advantage to compare the vital statistics of the various communities in these divisions, there should be reasonable uniformity of method in aiming at such estimates. Without some such uniformity it is clear that any useful comparison remains impossible.

THE GERMAN SURGICAL CONGRESS.

(FROM OUR BERLIN CORRESPONDENT.)

(Continued from p. 1514.)

Transplantation of Bones.

Professor **LEXER** (Königsberg) reported the results obtained by him in the transplantation of bones. He said that he had formerly used macerated bones taken from dead bodies and had inserted them under the periosteum where required; small cavities were in this way successfully filled, but in larger ones the inserted bone acted as a foreign body and was generally discharged by suppuration. He accordingly used fresh bone with periosteum which he got from amputated limbs and had in this way obtained excellent results, for the inserted pieces became united. As the presence of the bone marrow was found to produce pyrexia and irritation after the implantation it was previously removed and replaced by a plug containing iodoform which in course of time was absorbed. He gave the history of a series of operations performed by him in this way and explained his procedure. One very remarkable case was that of a man from whom he had removed the upper third of the tibia with the epiphysis, which was then replaced by a part of the tibia of the same size taken from an amputated limb; the knee-joint had comparatively good mobility. In a second case he had replaced an ankylosed knee-joint by an entire knee-joint taken from another person; the operation was successful and the mobility of the new joint was tolerably good. Bones taken from persons suffering from dry gangrene were very suitable for transplantation.

Dr. **REHN** (Frankfort) mentioned the case of a child whose hip-joint he had resected for coxitis. In order to obtain the formation of new bone he inserted a piece of ivory into the femur in the direction of the acetabulum. A radiogram showed that osseous tissue had developed and a serviceable limb was the result.

The Production of General Anæsthesia by a Combination of Scopolamine and Morphine.

Professor **NEUBER** (Kiel) expressed regret that the combination of scopolamine and morphine was comparatively little used as a general anæsthetic. In 250 operations which he had performed seven patients had scopolamine and morphine only, whilst in the remaining 243 cases ether was added. It was a great advantage that the patients could be anæsthetised in the ward and put on the operation table in a drowsy condition. The pulse was generally good during the anæsthesia; no excitement, vomiting, salivation, or asphyxia ever occurred. After the operation the patients continued in a drowsy state without feeling pain. Pneumonia was never observed.

A New Method of Producing Local Anæsthesia of the Extremities.

Professor **BIER** (Berlin) described a new method of producing local anæsthesia. If the limb to be operated on was the arm it was first emptied of blood by an Esmarch's bandage. A soft bandage was then put round it above and below the elbow and an incision was made in the median vein. Any blood which might have remained in the vein was then pressed out and a metallic cannula was inserted through which about 100 cubic centimetres of a solution of novocaine of 0·25 per cent. strength were injected. Analgesia of sufficient duration for the resection of the elbow at once occurred throughout the whole limb. In the lower extremity 150 cubic centimetres of the solution should be injected into the saphenous vein. To avoid the production of toxic symptoms it was essential that the bandage should be loosened by degrees; the analgesia disappeared a few minutes after the bandage was finally removed.

Treatment of Suppuration by the Ferment and Anti-ferment of Leucocytes.

Dr. **MÜLLER** and Dr. **PEISER** (Breslau) said that they had endeavoured to convert the "hot" suppuration of acute inflammation into "cold" suppuration by the administration of anti-serum. They used for that purpose either normal blood serum or hydrothorax fluid or ascites fluid containing anti-serum. On irrigation of an abscess with those fluids the purulent discharge became serous within 24 hours, and the granulation of ulcers was accelerated.

Disinfection of the Skin.

Dr. **VON BRUNN** (Tübingen) said that the skin could be efficiently disinfected by brushing it for five or ten minutes with alcohol of 95 per cent. strength without previously washing in water. He believed that by the astringent effect of alcohol on the skin the germs were fixed. He had found that this method gave just as good results as the complicated process of disinfection devised by Professor Fürbringer.

Dr. **HEUSNER** (Barmen) recommended for disinfection of the skin a mixture of iodine and benzene by which fatty substances were dissolved in a much higher degree than by ether.

Dr. **WEDERHAKE** (Düsseldorf) recommended for the same purpose a solution of tetrachloride of carbon of 0·1 per cent. strength which when brushed on the skin for a period varying from three to five minutes reduced the germs by 95 per cent. After the disinfection the skin was covered with "dermagummis," a solution of iodine and caoutchouc in tetrachloride of carbon.

Operations on the Brain.

Professor **VON HOCHENEGG** (Vienna) showed a patient from whom a tumour of the hypophysis had been successfully removed. He approached the hypophysis by way of the nose and temporarily opened the frontal sinuses which were abnormally large. He then resected the sphenoid bone and scooped out the hypophysis through the base of the sella turcica. The hypophysis was enormously enlarged. A strip of gauze was then passed from the nose through a drainage tube into the cavity and was removed on the eighth day. In three weeks after the operation the patient showed an improvement. The headache disappeared and the power of vision was better. The decline of the symptoms of acromegaly was especially remarkable. The hands became smaller and could now be closed, while the feet became so much smaller that the shoes which the patient had worn before going to the hospital were too large for her at the time of her discharge.

Operation for Graves's Disease.

Professor **KOCHER** (Berne) recommended an early operation in this disease. In his former series of cases he had had nine deaths among 167 patients, but in his recent series only two deaths among 153 patients. A careful examination of the blood was made in 106 cases, the result being that the red corpuscles were found to have increased to 5 000,000 and upwards per cubic millimetre, whilst the leucocytes decreased from 7000 to 700 per cubic millimetre, the principal reductions being in the polynuclear neutrophiles, whilst the lymphocytes the deficiency being made up by an annual State grant of kr. 15,000 a year.

Up to the present a little more than 1200 cases have been dealt with since the establishment of the hospital. Of these, 27 per cent. have been the subjects of superficial scrofulo-tuberculous lesions, 2 per cent. lupus, 3 per cent. visceral tuberculosis, and 50 per cent. tuberculosis of the bones, joints, and spine.

Dr. Sinding-Larsen, the medical superintendent to whom the institution is indebted for much of its success, took me over the whole establishment and favoured me with full particulars.[5] Treatment is mainly hygienic and dietetic and where necessary resort is made to the resources of orthopædic surgery. Fortunately there is no time limit. If possible patients are kept until they are cured. The average duration of residence is 300 days. Cases of Pott's disease and hip trouble are often retained for upwards of two years. The results appear to have been most encouraging. No less than 83 per cent. are returned as "considerably improved" and "improved." Only 17 per cent. were "not improved" or died. Of the fatal cases 50 per cent. were due to meningitis and miliary tuberculosis. The Fredriksværn Hospital is an institution concerning which Norway may be congratulated.

The Children's Marine Hospital at Hagevik.

A second seaside institution for tuberculous children is situated at Hagevik, which is reached from Bergen. Unfortunately, at the time of my winter visit to Norway the difficulty in reaching this part of the country was so great that a visit to it had to be omitted from my programme. Dr. H. G. Gade, the medical superintendent, has, however, kindly favoured me with copies of his reports,[6] which show that this institution is accomplishing an admirable service for the tuberculous children of Bergen and the western districts of Norway. This institution is now being enlarged and will shortly have accommodation for 100 cases.

Norway has much to show to the many in this and other lands who seem to think that little effective work for the tuberculous can be accomplished without an elaborate and expensive organisation and pretentious, and thus necessarily costly, establishments. Norway, in spite of financial, sociological, and geographical limitations, is accomplishing much towards the stamping out of its most deadly scourge. Other countries should mark and consider the means and measures which are proving so satisfactory in this land of the north.

THE BELFAST HEALTH COMMISSION.

(FROM A CORRESPONDENT.)

IN a recent communication addressed to THE LANCET by Colonel T. Walter Harding, chairman of the recent Belfast Health Commission, he states that when comparing the Belfast death-rate with that of other towns the Commission used the Irish Registrar-General's own estimates when comparing Belfast with other Irish towns, and estimates framed according to the method employed by the English Registrar-General when comparing Belfast with English towns, while for comparing the Belfast death-rate for a given year or period of years with the Belfast death-rate for another year or period of years the Commission made use of its own independent estimate of the population of Belfast. In looking carefully into this part of the report of the Belfast Health Commission it seems that if, to recall the famous dictum of the late Dr. Farr, "vital statistics form the basis of all health reform," they must be based on facts and not on assumptions, and that if comparisons are made as to the vital statistics of different places they must follow the same data. Now the very bed-rock of the vital statistics of any city depends (1) on its population and (2) on the comparison of its death-rate with that of other cities.

1. The population of a city in ordinary parlance is usually given as a certain number "at the last census" but in public health matters the question often arises, What is its population in intercensal years? To quote an example, Belfast was in population 349,180 in 1901 according to the census. What was the number of its inhabitants in 1906? The Belfast Health Commission in its report admits this "is somewhat difficult to determine," and as evidence of this it actually supplies us with four different estimates. (1) The Registrar-General for England, assuming that the population has increased since 1901 in the same ratio that was exhibited during the last intercensal period, would estimate at the middle of 1906 as 397,202. (2) On the other hand, the Irish Registrar-General does not, like his colleagues in Great Britain, estimate the population of communities in Ireland by assuming that the last intercensal ratio of increase or decrease has been maintained. His estimates are framed as the result of consideration of the birth-rate, of the effects of emigration and immigration, and of any local facts of which he can obtain knowledge, and as a result he, in giving evidence at the Commission, calculated the population of Belfast at the middle of 1906 as amounting to 366,220, or 31,000 fewer than an estimate framed according to the British method. (3) The Belfast corporation thinks this official estimate of the Irish Registrar-General is too low and that, as a corollary, the vital statistics based upon it are too high. The chairman of the public health committee estimated the population as being in 1906 388,159, and the city surveyor arrived at a somewhat similar figure as the result of a special inquiry, but in its report the Commission says:—

> In connexion with these estimates, both of which are largely based on the number of "empty" houses in 1906 as compared with the number of houses returned as "uninhabited" in the Census of 1901, it has to be borne in mind that the term "empty houses" and "uninhabited houses" are not synonymous, for the latter term includes business premises unoccupied at night, while the former does not. If allowance could be made for this discrepancy it might well be that both these official estimates would come to be nearly identical with the official estimate of the Registrar-General.

(4) Finally, the Commission, apparently not satisfied with any of the preceding estimates, makes one itself, based upon the number of births registered each year and concludes: "On the whole, therefore, it seems reasonable to assume that the population of Belfast in 1906 was approximately that given in the third column (Table I. showing the population of Belfast, as estimated in different ways, 380.500), namely, in round figures, not much more than 380,000."

Therefore we find the population of Belfast for 1906 is estimated as 366,220 (Irish Registrar-General), 397,202 (English Registrar-General), 388,159 (Belfast corporation), and "not much more than 380,000" (Belfast Health Commission). Such wide discrepancies (397,202 and 366,220) in figures warrant the conclusion that the estimate of the population of a large city like Belfast is, in an intercensal year, a mere speculation. The exact population will not be known until 1911 when it is possible that the estimate of the recognised Irish authority—Sir Robert Matheson—will turn out to be nearest the truth, inasmuch as his calculations are based on far more varied data than those employed in any of the other methods. The importance of having a correct knowledge of the population is shown in Table VIII. in the report of the Commission, where the death-rate of Belfast in 1906, based on populations as estimated (1) by the Registrar-General for Ireland, was 20·1; while (2) by the method of the Registrar General for England and Wales it was 18·6; and (3) by the number of registered births (the method of the Commission) it was 19·4.

2. How can the death-rate of a city like Belfast be compared with that of other cities in intercensal years? The Commission gets out of this obvious difficulty by using the figures of the Irish Registrar-General when comparing Belfast with other Irish towns, but when it comes to compare the death-rate with that of English towns it employs the method adopted by the English Registrar-General. Table IX. shows the death-rates of Belfast, Cork, and Dublin, based on populations as estimated by the Registrar-General for Ireland; but even in this respect there is doubt, as the Commission says, "such estimates are much less liable to inaccuracy in the case of Dublin and Cork than in the case of Belfast, in view of the less rapid increase of population in these two registration districts." In comparing the death-rate of Belfast with English and Scotch cities the Commission bases the Belfast rates upon populations estimated by the same method as that adopted by the English Registrar-General in order to make them comparable—that is, it makes the population of Belfast 397,202 instead of 366,220 as calculated by the Irish Registrar-General. Now there is great room for doubt in regard

---

[5] For full details of this interesting establishment and its excellent work reference should be made to the following, prepared by Dr. Chr. M. F. Sinding-Larsen: "Kysthospitalet ved Fredricksværn for Scrofulöse Börn," Kristiania, Steen'ske Bogtrykkeri, 1901;" and "Beitrag zum Studium der Behandlung der Hüftgelenktuberkulose im Kindesalter." Sonderabdruck aus *Nordiskt Medicinskt Arkiv*, 1905 and 1906 Stockholm, Kungl. Boktryckeriet.

[6] Aarsberetning for Kysthospitalet i Hagevik for 1906, Bergen, A. S. John Greigs Bogtrykkeri, 1907.

the rash made its appearance between the fourth and eighth day of the disease; in the majority on the fourth (10 cases) or fifth (14 cases) day. In addition to the ordinary routine methods of isolation, disinfection, &c., special precautions were taken to prevent infection by bites of fleas in infected houses in view of the suggestion that has been put forward that fleas may possibly be carriers of the specific virus. The check on "contacts" was most efficient; only one case was traceable beyond the borough and this was immediately isolated, so that no further harm was done. The success of Dr. Clayton's efforts is very striking; in three months the disease was stamped out entirely. The last outbreak of typhus fever in Gateshead began in 1881 and persisted uninterruptedly until 1889.

Northumberland and Newcastle upon-Tyne Sanatorium.

The sanatorium occupies an isolated position on the rising ground above the North Tyne at Barrasford. The hospital was opened on May 11th, 1907, and between that time and the end of the year 49 patients had been treated, of whom 24 were still in residence on Dec. 31st, the remainder having been discharged. Of the 49 patients, 29 were males and 20 females, the ages varying from 16 to 50 years. Of the 25 discharged, four were not improved, eight had shown some improvement, nine were much improved, and in four the disease was said to be arrested at the time of discharge. Inquiries four months later show that of the 18 males included in the 25 above-mentioned cases, six are at work and four are dead. With regard to cost, the sanatorium authorities state that the average cost per patient during 1907 (seven and a half months only) was £2 19*s*. 11*d*. per week; with 30 patients in residence the cost was about £2 8*s*. It is estimated that with 40 patients the cost will be covered by the fees charged—viz., £2 2*s*. per week; and with the full complement of patients—viz., 50, the cost may possibly come down to £1 15*s*. per patient per week. The sanitary committee of the Newcastle corporation is now proposing to pay the sanatorium authorities £2000 per annum for the use of 20 beds for patients sent by the corporation. The sanatorium had only been open for about seven months at the time when the first report was issued and though possibly it is hardly fair to criticise at such an early stage still, in view of the experience of other places, a stay of 13 weeks in the case of males, or of 16 weeks in the case of females (the average duration of treatment at Barrasford), is quite insufficient in the ordinary way to enable a patient to derive any material benefit. Symptoms may, no doubt, be temporarily relieved and patients be temporarily benefited by a short sojourn of three or four months at a sanatorium but it seems to be now recognised that a very considerably longer period of treatment is essential, even in quite early cases, for any material and lasting benefit to accrue. The recent able and exhaustive report by Dr. H. T. Bulstrode on sanatoriums is a work which would well repay close perusal by those concerned in sanatorium affairs.

Examinations in Medicine, &c.

The secretary of the College of Medicine draws the attention of all candidates intending to present themselves for examination in medicine, surgery, hygiene or public health to the fact that the examinations in Newcastle are now held in March and July instead of as heretofore in April and September. The next examinations will commence on Monday, July 13th next.

June 8th.

THE WINSLEY SANATORIUM.—The health committee of the Bristol city council has under consideration a proposal from the authorities of the Winsley sanatorium. At present patients stay for a period of 16 weeks, but after two months it has been found in many cases that one of two results is obtained—either that there is so little response to treatment that a prolongation of the stay is useless or that the patient has acquired such a knowledge of the treatment that a continuation away from the sanatorium is possible. This being so, it is recommended that in future two months should be the usual period allowed at the institution on the understanding that there shall be provision for a stay of four months if considered advisable. A strong point in favour of the proposition is that it will allow of so many more patients being treated. It is stated that the other public bodies connected with the sanatorium have agreed to the recommendation.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Professor of Medicine in the University of Glasgow.

SINCE the death of Sir Thomas McCall Anderson some months ago the chair of Practice of Medicine in the University of Glasgow has been vacant. This week it is announced that the King has been pleased to appoint Dr. Samson Gemmell to the chair. Dr. Gemmell is a graduate of Glasgow, having taken the degree of M.B. in 1872 and of M.D. in 1880. For eight years he discharged the duties of assistant to Sir William Gairdner in connexion with the chair of Practice of Medicine, and he was also clinical assistant to him in the Western Infirmary for a period of four years. In 1887 he was elected physician to the Royal Infirmary and five years later he became physician to the Western Infirmary. In 1880 he was appointed to the chair of Practice of Medicine in Anderson's College Medical School. In 1900 he succeeded Sir Thomas McCall Anderson in the chair of Clinical Medicine. By the appointment of Dr. Gemmell to the chair of Practice of Medicine the chair of Clinical Medicine now becomes vacant.

Scarlet Fever and Milk-supplies.

The medical officer of health of Glasgow has drawn attention to the difficulty which may attend the operation of existing provisions for stopping a milk-supply associated with the occurrence of infectious disease among its consumers. The following case was used to illustrate the difficulty. Attention was directed recently to a milk-supply among the consumers of which certain cases of scarlet fever were occurring. It was ascertained that milk from the same source was being sold at a second dairy in the town and among the consumers here also cases were occurring. The employees of the dairies, as well as of the farm, were examined without any illness which would explain the outbreak being discovered, yet the contemporaneous occurrence of cases on both sections of this milk-supply among persons who had nothing else in common seemed inevitably to suggest the milk-supply as affording the explanation. Viewed in relation to existing legislation some difficulty might arise in a case like this, for while Section 18 of the Glasgow Police (Amendment) Act, 1890, proceeds on the assumption that infectious disease is recognisably present at the source of supply, the Public Health (Scotland) Act, 1897, Section 60, requires "evidence" that disease is being spread in its distribution. It is questionable whether anyone would be justified in maintaining that the foregoing occurrences constitute "evidence" as required by the Act, but they certainly afford reasonable ground for assuming that infection had by some manner not ascertained gained access to the milk before delivery.

Presentation to Dr. Bruce Goff.

The annual dinner of the members of the Glasgow and West of Scotland Branch of the British Medical Association was held last week in the St. Enoch Hotel. The chief feature of the evening was the presentation of a silver Warwick vase and four fruit dishes to Dr. Goff in recognition of the valuable service rendered to the branch, whose representative on the general council he has been for the long period of 25 years.

Meeting of Medical Men on behalf of the Ruchill Medical Officers.

A meeting of the Glasgow and West of Scotland branch of the British Medical Association was held recently in Glasgow to consider the case of the resident physicians who were recently dismissed from Ruchill fever hospital. The meeting, which was very largely attended, expressed its sympathy with the medical officers. It was decided to open a fund to help towards the payment of their legal expenses.

Lady Sanitary Inspector for Port Glasgow.

During the past few years the Port Glasgow town council has several times had under consideration a proposal to appoint a lady sanitary inspector in the burgh, but while sympathising with the suggestion the council could not see its way to incur the expenditure which such an appointment would entail. The matter has, however, now been settled by the generous action of a Port Glasgow lady who has intimated that she is prepared to pay the salary of a lady sanitary inspector for three years. The town council has decided to accept the offer.

increased. After the operation the polynuclear leucocytes very soon increased, while the lymphocytes decreased. In the prognosis a decrease in the neutrophile leucocytes and an increase in the lymphocytes were unfavourable conditions. The chance of recovery rose in accordance with the size of the piece of gland which was removed. Professor Kocher had observed that in Graves's disease the coagulability of the blood was impaired.

Operations on the Cervical Glands.

Professor DOLLINGER (Budapest) recommended that in the extirpation of tuberculous cervical glands the incision should be made on the posterior part of the neck, in order that the cicatrix might be covered by the hair and so become less visible than if it was on the front of the neck. He had operated on 200 cases in this way; in 167 of these patients primary union was obtained, whilst in the remainder the discharge ceased within a few weeks. The glands were drawn by forceps into the incision and successively cut away. Cases in which the skin was already thin were, of course, unfit for this method.

(To be continued.)

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Pulmonary Tuberculosis.

AT the last meeting of the Prestwich board of guardians a letter was read from the Grimsby union asking the board to support a resolution in favour of provision by the State of district or county sanatoriums, so that all classes may receive treatment on the latest scientific lines for pulmonary tuberculosis. Some may question the wisdom of looking to the State as the universal provider. But apart from that these cases, the chairman said, had been generally taken over by local authorities. It had never been a question for the State before, "though, of course, if the State would take it over it would be a great relief to the authorities." In the end it was decided to comply with the request. The Stockport guardians on June 4th adopted a resolution to the effect that the time had arrived when the State should provide district or county sanatoriums and that the various boards of guardians should be asked to make a united appeal to the Government to promote legislation on these lines. At a meeting the other day of the Lancaster board of guardians a member said that there was a continual crop of cases of pulmonary tuberculosis at the workhouse and that it was unfair that inmates, especially young people, should be exposed to the risk of infection. It was dangerous, he said, for people to occupy a house where a patient had died from consumption unless it had been thoroughly disinfected, "yet they allowed people in the last stages of phthisis to lie in open wards with people of all ages and conditions of health and unaffected by the disease." If this is so, it certainly points to some want of classification at Lancaster. One of the disheartening experiences connected with hospitals for consumption is, that however much patients may have improved while in hospital, they are not immune against fresh attacks, and after returning to their homes too often appear again at the hospital in a worse state than before. In Manchester the thorough disinfection of the patients' homes, at first disliked by the friends but now welcomed, has certainly been beneficial. It is a good sign that the old fatalistic *laissez faire* ideas are losing their hold.

A Frank Defaulter.

It is not often that the attempts to pass off unsound as sound meat are relieved by a flash of conscious, or perhaps unconscious, humour, but this happened at Preston the other day. A man was fined £5 and costs for exposing the unsound carcass of a pig for sale. He said that he had been bringing pigs to the market for 30 years and would not have brought this if he had known it was wrong. The butcher told him that it was all right. But the chairman told him that he must have known it was not right, and the defendant innocently remarked, "It would have died if I had not stuck it myself."

Adulterated Butter.

The persistent attempts to palm off adulterated butter as genuine seem to show that the game, when successful, is very profitable. From a case that occurred recently where a man was summoned for selling as butter a preparation containing 80 per cent. of margarine, it appears that a considerable organisation is at work to carry on the practice. For the prosecution it was stated that it was not a mere instance of a person keeping a small shop but that they were dealing with a very numerous class. The defendant was ordered to pay a penalty of £20 and costs.

Ignorance as to Anthrax.

A short time ago a farmer at Whitefield was fined £5 and costs for exposing anthrax meat for sale in the Manchester market. He pleaded ignorance and said that he did not know that the cow was suffering from anthrax. The magistrate accepted the plea and imposed a lighter fine than he otherwise would have done. Surely all those who have to do with cattle should know how to detect anthrax.

Bequests.

By the will of Mr. Edward Aston, a Manchester merchant, nearly £40,000 have been left to religious and philanthropic societies, and also to the Northern Counties Hospital for Incurables and to the Manchester Cancer Hospital and Home £1000 each.

June 9th.

NEWCASTLE-UPON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

The Recent Outbreak of Typhus Fever in Gateshead.

Dr. T. M. Clayton, the medical officer of health of Gateshead, gives in his annual report for 1907 some interesting facts relative to an outbreak of typhus fever (happily limited) with which he had to deal between the end of October, 1907, and the end of January, 1908. There were 49 cases in all. From the report it appears that on Oct. 25th Dr. Clayton had his attention drawn to three cases of illness the characters of which aroused a suspicion of typhus fever. Three days later five other similar cases were brought to his notice. In all these cases there was a history of severe illness with fever lasting a fortnight or longer. When seen for the first time there was no rash and the blood failed to react to the agglutination test for enteric fever. The cases were isolated and a diagnosis of typhus fever was made, which was confirmed by the course of the illness in the later cases which were observed from practically the day of onset. The subsequent cases were all traceable to contact with the earlier ones and by far the greater number of them were discovered by the staff of the health department. A nurse was the only person on the special staff employed in connexion with the outbreak who contracted the disease. Dr. Clayton is of opinion that the cases which he saw on Oct. 25th were not the first to occur in the borough. He was led to believe that three deaths certified as due to pneumonia were in reality cases of typhus fever. The first of these deaths occurred on August 31st. Beyond this he has been unable to trace the origin of the disease or the channel through which it gained admittance to the district. 47 cases occurred in 18 houses, with an average of 2·8 rooms and 6·2 inmates per house. Eight cases were removed from one house. The majority of the houses were "dirty, verminous, and ill-ventilated." The density of the population in Gateshead is 38·9 persons per acre. The cases were limited to the north and central parts of the borough. The incidence of cases and population per acre in the several wards affected are as follows:—

Wards.	N.	N.E.	N.W.	E.C.	S.C.	W.C.
Number of cases of typhus fever... ...	1	7	26	12	1	1
Population per acre	91·9	29·4	39·4	166·1	49·5	109·6

All ages were equally affected, the youngest being three weeks and the eldest 51 years. 20 males and 29 females suffered. The deaths numbered four (8 per cent.), two males and two females. In those cases in which it was observed for that popular seaside summer resort. It is interesting to note that wherever the Tuberculosis Exhibition has gone the Local Government Board has had less trouble in carrying out public health reforms.

Death of Mr. Sidney Brice Smyth, M.A., M.B. Dub.

The medical profession received a real shock when it was announced on Thursday morning last that Dr. Sidney Brice Smyth had died suddenly at his residence, Ulsterville House, Lisburn-road, Belfast. On the evening before he dined with his father (Dr. Brice Smyth), after a hard day's work, without manifesting any signs of illness and retired to rest as usual, but in the morning (June 4th), when his servant went to arouse him, he was found dead from heart failure. For some time past he had been breathless on any great exertion, and at times had presented a cyanosed appearance, and he was arranging to go for a holiday. At the time of his death he was 39 years of age. Dr. Smyth, after being at school at Uppingham, studied at Trinity College, Dublin, where he graduated in medicine in 1890. In the same year he began practice in Belfast and soon, as a result of his energy and ability, established for himself a good position. He was physician to the Belfast Hospital for Sick Children and to the Maternity Hospital, to both of which he rendered valuable services. Dr. Smyth was a keen sportsman, being specially fond of yachting, fishing, and motoring. A personal favourite and a man of most gentlemanly bearing, he was greatly respected by a large *clientèle* of patients who deeply deplore his sudden death. The keenest sympathy is felt with his aged father, a very well-known member of the medical profession in Belfast. Dr. Smyth was unmarried.

The British Dental Association.

The annual conference of the members of the British Dental Association, which now numbers 1675 members, took place during the Whitsuntide holidays in Belfast. On Friday night (June 5th) Mr. L. Matheson, L.D.S., of London, gave a popular lecture, which was very largely attended, on "The Teeth of the People: a National Asset." On Saturday morning, June 6th, in Queen's College, Belfast, after some valedictory remarks from the retiring President, Mr. J. C. Oliver, L.D.S., of Cardiff, the new President, Mr. J. J. Andrew, L.D.S., of Belfast, took the chair and delivered a very practical address in which he referred specially to the importance of the inspection of school children *to see* the condition of those organs which are most often at fault—the eyes, the ears, and the teeth—and emphasised the fact that the physical condition of children was almost of more importance to a nation than education. In the afternoon Dr. J. Sim Wallace gave an address on "Diet in Infancy and Childhood"; Mr. C. E. Wallis, L.D.S., of King's College Hospital, London, spoke of the necessity of dental clinics; Mr. A. Layton, L.D.S., gave an address on "Experience of Dental Inspection and Treatment in the Kettering Elementary Schools"; while Mr. G. Cunningham, L.D.S., contributed an interesting series of statistics illustrative of his experience of a school dental clinic in Cambridge. The annual dinner took place in the Grand Central Hotel, Belfast, on Saturday evening when the President occupied the chair, and 175 members and guests were present. This entertainment was a marked success. A series of scientific papers were read on Monday and the annual meeting of the Benevolent Fund was held; in the evening the President of the Association and the members of the Irish branch held a reception in the Grand Central Hotel, at which dancing, whist, music, &c., were the features of the evening. One of the most popular exhibits at the meeting was a demonstration given by Professor J. Symington, F.R.S., and Dr. J. C. Rankin showing the development of both the primary and the permanent teeth in young people as illustrated by the x rays method. The radiograms were much admired and Professor Symington was cordially thanked.

June 9th.

PARIS.

(From our own Correspondent.)

The Etiology of Sydenham's Chorea.

At the French Society of Oto-Rhino-Laryngology M. de Ponthière has communicated the results of his ten years' observations on the etiology and treatment of chorea. The rapid and permanent cures obtained by removing tonsils which are chronically infected and adenoid vegetations point to the conclusion that chorea is generally the outcome of an auto-intoxication produced by swallowing septic material secreted by the lymphoid organs of the naso-pharynx. This naso-pharyngeal infection is nearly always rheumatic. The pharynx is responsible for the cardiac and articular manifestations of rheumatism which follow on septic or gouty sore-throats. The author adduced the analogy of other local and general symptoms which are common to "adenoid" and to choreic patients, such as deficient nasal respiration, disturbed nights and night-terrors, dyspnœa, tender spots in the side, muscular and intellectual disabilities, difficulty in concentrating the attention (aprosexia), alterations in the character, digestive disturbances and distaste for food, especially in the morning, lymphatism, and the stupid aspect of choreics which is the same as the adenoid facies. The examination of the naso-pharynx is thus of the highest importance in cases of true chorea, as the origin of the neurosis will be often discovered there.

The Employment of Women and Children.

The Minister of Labour has introduced into the Chamber a Government Bill to authorise the public administration to lay down by order the different classes of work dangerous to health or morality which are to be forbidden to women and children under 18 years of age in the establishments *coming* under the Health and Safety of Workers Act. The object of this measure is to secure to women and children employed in commercial establishments the same protection as is assured to those employed in workshops and factories.

The Wording of Medical Certificates by Practitioners.

The Appeal Court has recently delivered an interesting judgment which puts a certain responsibility upon medical men in drawing up certificates for the detention of insane persons in asylums. It arose from a practitioner adding to such a certificate certain libellous remarks about the patient's neighbours who brought and won an action for damages against him. The defendant took the case to the Court of Appeal which upheld the verdict, holding that a medical man has not an absolute discretion in the wording of certificates, especially when it comes to speaking about third parties whose mental condition is not in question, and that such remarks may be libellous and the proper cause for an action for damages.

Charges against Medical Men.

Two criminal charges against medical men have been occupying the courts recently. The first is concerned with a Dr. B. together with a workman who took service with a master carpenter on August 17th in last year. Three days later he sustained an injury to his thumb in the course of his work which a Dr. J. diagnosed as a sprain; on Sept. 2nd this same medical man certified the patient as cured and fit to resume work. On the strength of this certificate the Common Industrial Fund allowed the man 35 francs temporary indemnity. Three days later, however, he went to consult Dr. B., the defendant in the present case, who treated him until Oct. 10th, when he gave him a certificate dated Oct. 8th to say he was cured, on the strength of which he obtained a further grant of 93 francs from the aforesaid fund. In the meantime, on Sept. 11th, the carpenter had calmly taken a fresh job under a new master, and three days later he stopped work again, pretending that he had injured the same thumb. This time he was looked after by a Dr. A., who on Sept. 23rd signed him up as cured. His second employer paid him 35 fr. 75 c. compensation. On Sept. 27th he went again to Dr. B., who treated him until Oct. 15th, when his second employer paid a fresh compensation of 91 francs. So between Sept. 11th and Oct. 8th he was being paid half wages by two employers, whilst Dr. B. received fees amounting to 70 fr. 50 c. from the employers and the fund. When these facts came to light the man's last employer charged the workman, together with Dr. B., with conspiracy to defraud. The former confessed his double-dealing, but Dr. B. strenuously denied his complicity. The court condemned the workman to pay a fine of 25 francs and to go to prison for six months, and Dr. B. to pay 500 francs, to forfeit his right to practise medicine for five years, and to six months' imprisonment, and further, the two defendants were condemned to pay 500 francs damages to the plaintiffs. In the second case judgment has not yet been delivered, but it concerns a picture-dealer who is also an insurance agent, and who is charged with having conspired with his medical attendant to defraud insurance companies on a large scale. He is alleged to have effected insurances upon the lives

Founders' Day at Queen Margaret College, Glasgow.

Last week the lady students and graduates of Queen Margaret College took part in the celebration of Founders' Day. The guests were received by Miss Galloway, LL.D., in the hall of the College. In giving an account of the work done at the College during the past year Miss Galloway referred to the fact that a house had been leased as temporary premises for Queen Margaret Students' Union, as the committee had thought it better not to fix on a site for the permanent building till everything was settled as regards the new class arrangements at the University and Queen Margaret College. The rent and upkeep for this temporary building would be paid from the interest of £8000 already raised for the Union Fund, and thus the capital would be left untouched for the new building. Another important advance made during the year was the purchase of the Queen Margaret Hall of Residence.

Medical Inspection of Greenock Schools.

For some time the question of the medical inspection of schools has been exercising the town council of Greenock. In a Provisional Order which it is at present promoting powers are sought to undertake this work. The school board is resenting this; consequently a meeting has taken place between the committee in charge of the Provisional Order and a deputation of the school board. The latter body alleges that the Education Bill for Scotland placed on school boards the duty of appointing medical inspectors for the schools with the object of having the health of the children properly attended to. If, however, the clause in the Provisional Order were passed there might be conflict between the officials of the corporation and those of the board. It was also pointed out that under the Public Health Act the corporation had already power to enter schools where infectious disease was suspected, and this, it was suggested, was sufficient for the purpose of the local authority. Before coming to any final decision in the matter the Provisional Order committee agreed carefully to consider the views of the school board.

Inverness District Asylum: Appointment of Medical Superintendent.

A meeting of the Inverness district lunacy board was held on June 5th in the county council buildings, Inverness, for the purpose of appointing a medical superintendent for the Inverness district asylum in succession to Dr. R. B. Campbell, who was recently appointed medical superintendent of the Larbert asylum. 23 applications were submitted for the appointment. The final vote took place between Dr. Theodore Charles Mackenzie, senior assistant physician, Royal Asylum, Aberdeen, and Dr. Charles John Shaw, senior assistant physician, Glasgow Royal Asylum. Ten votes were recorded for each of these two candidates and the chairman gave his casting vote in favour of Dr. Mackenzie who was accordingly declared appointed. Dr. Mackenzie, who is 34 years of age, is a graduate of Edinburgh University. He had charge of the male side at Morningside Asylum for three years. In September, 1907, he attended the International Congress on Neurology and Psychiatry at Amsterdam as the delegate of the Aberdeen Medico-Chirurgical Society. He has also visited the asylums in Rome, Naples, Florence, and Reggio Æmilia.

June 9th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Tuberculosis in Ireland.

A RETURN issued by the Registrar-General shows that during the year 1907 the deaths from all forms of tuberculous disease registered in Ireland numbered 11,677, which is very slightly under the number in 1906, which was 11,756, but it will probably work out at a larger percentage owing to emigration.

Medical Men and the Workmen's Compensation Act.

A case of great interest to the medical profession was tried at the Enniscorthy quarter sessions two weeks ago before county court Judge B. Barry, K.C., in which Mrs. Murphy, widow of the late Mr. D. P. Murphy, L.R.C.P. & S. Irel., medical officer of Killane Dispensary, claimed for compensation for the loss of her husband who was killed in the discharge of his duties. She claimed on behalf of herself and four children between the ages of 10 and 16 years. They were wholly dependent on the earnings of Mr. Murphy, whose salary as medical officer was £120 per annum. On Oct. 15th, 1907, a woman, a maidservant of a farmer in the country, was accidentally shot, and on his way to the scene of the accident Mr. Murphy was thrown from his trap, receiving injuries from which he died on the following day. It was submitted that Mr. Murphy was in the employment of the guardians, who were a corporate body, and that there was a contract of service and that he was a workman within the meaning of the Act. The guardians disputed this view. I give the county court judge's decision in full:—

> His Honour: I was going to reserve my judgment in this case, but I don't think I will, because it seems if the intention of the Legislature is not carried out it is the fault of the drafting of the Act of Parliament. From the wording of the Act it is hard to know what was really intended. The proper way to have drawn this subsection was to have defined "workman" as any person and then it would have applied to every person, subject only to the exceptions in Section 9. But the real words that have been followed are "whether by way of manual labour, clerical work or otherwise, and whether the contract is expressed or implied, is oral or in writing." That seems a bit ambiguous. Every contract must be expressed or implied, must be oral or in writing. The drafters of the Act certainly complicated matters very much by inserting, too, "clerical work or otherwise." Because the words manual work or otherwise would restrict the construction of the section to be something which would have the same kind of service as manual labour or clerical work, but what other kind of service is there of the same sort as manual labour or clerical work? I cannot see how you can construct "otherwise" by *ejusdem generis*. There is nothing *ejusdem generis* to clerical work only clerical work, and if I am wrong I will put it in proper order to have it set right. I think the *ejusdem generis* construction, not being applicable, means "otherwise" must get a full and unrestricted meaning, and therefore, subject to what might be said by the Court of Appeal, I will not take the responsibility of throwing out this application. I will reserve this point and conditionally award the sum of £300.
>
> Mr. O'Dempsey, solicitor for the Enniscorthy board of guardians: I ask the Court of Appeal to say whether the deceased was a workman or not within the meaning of the Act. Have you put the general question?
>
> His Honour: Yes. If, in the opinion of the Court of Appeal, the deceased was a workman, I award that the applicant is entitled to the sum of £300—£100 to go to the widow and £200 to be invested for the children in equal shares in the Post Office Savings Bank. The money will be lodged in my name and also Mr. Meadows's
>
> Mr. O'Connor, counsel for applicant: The guardians may not go on with the appeal at all.
>
> His Honour: If they don't prosecute the appeal you will get the order, Mr. O'Connor.

The guardians have appealed and the case will be tried at the Trinity sittings of the law courts in Dublin.

Notes on Sanitary Measures in Ulster Towns.

It is good to find that, thanks largely to the efforts of the Women's National Health Association of Ireland, public health is now getting a due share of attention throughout the country. Recently the Local Government Board of Ireland issued a circular letter on the subject of dairies and cowsheds, pointing out that officers appointed for the inspection of cowsheds and dairy premises should be instructed to make a thorough examination of their respective districts with a view to having all cowkeepers coming under the provisions of the Order registered. The circular also pointed out that as the cattle were now out on grass the requisite structural improvements in the cowsheds should be effected before their return in the autumn. This Order has had a mixed reception, as a rule the urban being more in its favour than the rural councils. The medical officer of health of Lurgan, Dr. Samuel Agnew, in his annual report for 1907, just issued, shows that the general condition of his district has been very satisfactory. With the exception of one death each from scarlet fever and diphtheria, none were due to any of the notifiable infectious diseases. The general death-rate was 19·3 and the zymotic death-rate was 1·4. Special details are given in regard to tuberculous diseases and the greatest hope is expressed that the health association inaugurated by Lady Aberdeen will do much to educate the people in regard to these diseases. Dr. Agnew's report is illustrated by excellent comparative statistical tables. On the advice of Dr. Agnew the people of Lurgan have decided to have their streets more frequently and regularly watered to obviate the danger and nuisance of the dust raised by motors. Omagh urban council had recently before it the question of the sale of methylated spirits for consumption as an alcoholic beverage and it was considered that it should be scheduled as a poison. Mr. Robert Currie, medical officer of health, has drawn the attention of the Ballymena urban council to a large number of insanitary houses in its district, and the Newcastle urban council is arranging to have a report from an engineer on a combined scheme of sewerage, water-supply, and electricity especially with anthropological studies, which he is anxious to see finished. He is the author of the well-known anatomical atlas bearing his name, which introduced a new method of illustrating dissected specimens, and of a widely-read text-book. The lectures of Professor Toldt were always well attended, for he had the faculty of inspiring his students with true scientific enthusiasm.

A Threatened Strike in the Bohemian Hospitals.

The medical staffs of all the hospitals in Prague have, with the exception of the consulting physicians, announced their intention of giving simultaneous notice if their grievances are not adjusted speedily, and the professors are helping their juniors by testifying that they cannot do without them. The main points of difference of opinion are the payment and the food, whilst the staff also requests that proper provision should be made for sickness and leave of absence. Here, as in all such affairs, "red tape" is responsible for the conflict, but the profession has decided to make a stand once for all and careful provision has been made to prevent the hospital boards from finding any medical man willing to take over the work if the strike really occurs on July 1st, which date has been fixed as the latest for the adjustment of the questions in dispute. If Prague be successful no doubt Vienna will follow suit, for the controversies here also are only postponed, not adjusted.

The So-called Lion-Man (Hirsuties Congenita Universalis).

Dr. Grosz showed at a meeting of the Medical Society a man who has been the object of much interest to the public and has been "shown" as a "lion-man" in many countries. He is a young Russian, said to be 17 years old, covered over the whole body with fine lanugo hair except on the head where the normal hair is present. The direction of the growth of hair corresponds on the body, especially on the face, with the fœtal growth of hair. In concordance with the hypertrichosis (consisting of fine, yellow-blonde, soft, long silk-like hair) there is a rudimentary development of the alveoli and teeth. Lionel, as the youth is called, has only two teeth, corresponding to incisors, in the lower alveolus; the x rays failed to show the presence of any dental sacs in the alveoli. In dogs showing abnormalities in their hair growth similar disturbances of dentition have been observed. Cases of this kind are very rare; hitherto only 24 have been recorded by Bartels. One of the oldest is the family, described and painted in 1583 by Plater, consisting of father, mother, two boys, and one girl, all of whom were covered with an ample cloak of hair, especially on the face and breast and back. It is remarkable that the majority of the cases belonged to the Slavonic race (Russian Poles). As regards the explanation, Unna's and Siebold's hypothesis is the most likely one: a persisting and continually growing fœtal hair germ, a theory which is supported by the direction of the hair in the case shown.

Septic and Aseptic Hydronephrosis caused by Constricting Blood-vessels.

Dr. Moszkowicz and Dr. Blum recently had an opportunity of showing patients in whom an abnormal course of the renal vessels gave rise to very dangerous symptoms, causing hydronephrosis. In the first case a woman, aged 20 years, suffered every 12 to 14 days from attacks of intense abdominal pain. During such an attack a tumour in the right half of the abdomen could be palpated, but the urine was clear and free from abnormalities. A simple hydronephrosis was diagnosed and in the operation it was observed that the tumour, which was of the size of a large cucumber, consisted of the renal pelvis, whilst the ureter was completely constricted between two taut abnormal vessels about one inch below its upper end. When the vessels were divided the ureter at once was filled with the contents of the sac. An anastomosis between the ureter and the renal pelvis was made in order to facilitate matters. The kidney, which hitherto had not secreted any urine into the bladder (proved by the ingestion of indigo-carmine before operation), resumed its function and the patient made an uneventful recovery. The three cases shown by Dr. Blum were caused by the ureter being constricted by an abnormal renal artery and all three kidneys had become cystic with grave symptoms (colic, polyuria alternating with oliguria, fever, and rigors) pointing to septic infection of the cysts. The patients were girls, aged 20 and 28 years, and a youth, aged 16 years, and diagnosis could be made also by uretero-catheterisation. The coincident occurrence of the cases is rather remarkable, as sometimes years pass without such a case being observed. As regards the prognosis it must be stated to be good, since a careful operation (nephrectomy) is sure to cure the patient, provided the other kidney is sufficiently healthy. Most of the authors are of opinion that two factors must be present to bring about the condition—abnormal blood-vessels and abnormal mobility of the kidney. Then a compression of the ureter may occur with its disastrous results. Functional examination with the modern methods shows whether the remaining parenchyma of the kidney is active enough to be spared or whether the entire organ must be removed.

June 8th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

The Sixteenth International Congress of Medicine.

THIS Congress will be held at Budapest from August 29th to Sept. 3rd, 1909. The organising committee has already done a great deal to insure the success of the scientific side of the congress and an entertainment programme is well in hand which should insure the social enjoyment of its members. A meeting of this committee was held in May. The scientific publications of the congress will be issued in two parts. The first part, in 21 sections, will contain the prescribed proceedings; the second part, in 22 sections, will contain the discussions and the notified addresses. The formal opening will take place on August 29th. Guests will be invited by the Government and also by the city of Budapest, which will issue to members of the Congress beautifully illustrated and bound souvenir books containing a description of the notable medical institutions of Hungary and views of Budapest and its suburbs.

The Budapest First Aid Society.

On May 10th the twentieth anniversary of the First Aid Society was celebrated. In connexion with this a National First Aid Congress has been held at Budapest, to which congress medical men, teachers, and police officials were invited. There was also a small exhibition arranged by the State railways, at which many modern improvements in railway ambulance cars and motor ambulances were shown. Dr. Geyer, chief police medical officer, delivered an address on the Policeman as Life-Saver.

"Ostanxin," a New Antirachitic Drug.

Dr. Furka has treated a number of rachitic cases with "ostanxin" (calcium paranucleinicum) made by the chemical works of Richter Gedeon of Budapest. Ostanxin is a fine, tasteless powder made from casein by a process of pepsin and hydrochloric acid digestion. It contains 17 per cent. calcium, 9 per cent. nitrogen, and 2½ per cent. phosphorus. As it is easily soluble in water, it can be readily given to children in milk, coffee, and other liquids. Its administration is especially indicated at first for rachitic and scrofulous children, for it helps the development of bones and promotes metabolism, as is proved by the increase of weight after a relatively short time. Dr. Furka has found it a useful tonic for patients convalescent after acute infectious diseases. Children generally take it without dislike, and the records of their weight have shown a noticeable increase in every case. Dr. Furka's cases were admitted into hospital from unhygienic dwellings, and such children enjoying in hospital fresh air and good food would have increased in weight probably without the exhibition of any drug. The drug has been administered in cases of renal hæmorrhage, too, on account of the calcium which it contains. As it was stated that after its administration the albumin excreted in the urine did not increase, whereas in some cases it decidedly decreased, larger doses of the drug have been given to patients. It never did harm to the patients. In some cases the bleeding has abated rapidly under its employment, while in other cases it had no effect at all. In renal complications of scarlet fever Dr. Furka used the drug with benefit. The dose of ostanxin is from one to two grammes three times a day.

The International Society of Medical Abstainers.

This society has issued a circular to Hungarian medical men with the following text:—

> The undersigned physicians of every country appeal to every ruler, government, and parliament, and all teachers, clergymen, and others who have at heart the well-being of the present and future generations.
>
> We, who are members of the medical profession and are particularly

of persons whose health was seriously damaged, often by tuberculosis, and to have substituted healthy persons at the medical examinations for policies.

The Treatment of Keloids by Radium.

At the Academy of Medicine on May 26th M. Wickham and M. Degrais communicated a paper upon the curative effects of radium, in continuance of earlier observations which had convinced them of the favourable effect of radium on epitheliomata of the skin and on vascular nævi. Their new work bears on the treatment of unhealthy scars. They exhibited a number of photographs showing scars, the results of tuberculous lesions, burns, and various injuries, which had disappeared or been greatly diminished in size, and others which showed the specific kind of action which radium exercises over keloids of various forms—for instance, præsternal and spontaneous keloids and those following on acne, anthrax, and scars of wounds. The authors laid stress on the painless and convenient method of application which the treatment permits and which renders it suitable for children of very tender age, and they add that some tumours disappear quietly without the necessity of securing a visible therapeutic reaction. They regard radium as having a selective curative affinity for such affections of the skin as epitheliomata, nævi, and keloids.

The Treatment of Deaf-mutes.

At the same sitting of the Academy of Medicine M. Castex described the training methods employed at the National Institution of Deaf-mutes in Paris. Oral education is relied on to the exclusion of all forms of apparatus, the pupil being trained by slow degrees by the senses of sight and touch to reproduce the movements of the teacher's lips and to emit more or less organised sounds. He gradually learns to read the lips as though they were a written book. The improvement in hearing and vocalisation takes place *pari passu*. As 25 per cent. of deaf-mutes have some trace of hearing M. Castex attempts to cultivate these traces by means of his natural voice. The voice attained by deaf-mutes is as yet monotonous and imperfect and workers in this field are trying to improve its musical quality. M. Castex based his remarks upon the examination of more than 1000 children which he has made during the last ten years.

Laryngotomy for Stenosis of the Larynx.

M. Sieur described this procedure at the Chirurgical Society on June 3rd. He performed laryngotomy on two patients with stenosis of the organ, one case having been caused by typhoid laryngitis and the other by diphtheria. It is necessary to keep the larynx open by fixing the edges of the thyroid wound to the skin. The results have been excellent. M. Broca supported the procedure, which he has also found a useful one, and M. Morestin declared that he would adopt it in future, having completely failed to relieve one of his patients by dilatation.

June 8th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Society for School Hygiene.

THE Swiss Society for School Hygiene, which now has 626 members and 110 associate members, held its ninth annual meeting on May 16th and 17th in the pretty little town of Baden near Zürich, well known for its sulphur springs. The meetings were well attended as a subject of general interest was discussed—namely, forest schools and forest recreation for school children. Dr. Kraft, medical school officer of Zürich, spoke on the medical side of the question, Mr. Hiestand on the educational side, whereas the mayor of Lausanne, M. Schuetzler, illustrated these lectures by narrating the practical experiences which they had already gained at Lausanne, a pioneer town in this new movement in Switzerland. These forest schools are intended for constitutionally weak children whose poor health renders them unfit for the usual school routine. They must be placed near the forests which abound in Switzerland and be fairly easy of access. Class-rooms, rooms for recreation, for rest (*Liegehallen*), rooms for meals, for baths, &c., are to be provided. The classes, which must not exceed 25 children, are to be placed under the continual supervision of the medical officer. The lessons are not to be more than half an hour at a time and altogether two hours per diem. The rest of the day is to be occupied by the simple and wholesome meals, recreation, rest, and baths (simple and saline). Much time can thus be devoted to strengthening the physique, developing the character, and to teaching punctuality, order, &c. The society unanimously adopted a proposition recommending education authorities, teachers, and parents to give every aid possible in instituting such forest schools. The society also resolved to hold a fortnightly course of instruction in the care of the young in September next in Zürich. The mornings are to be reserved for lectures which eminent lecturers, German, Austrian, and Swiss, have been invited to deliver; the afternoons will be devoted to visits at various institutions; in the evenings social meetings or meetings for discussion will take place. Later a similar course is to be held in French Switzerland. Dr. Guillaume, director of the Federal Statistical Bureau in Bern, spoke on the part which ladies should take in sanitary supervision of school children. Dr. Steiger of Lucerne gave a report on the school dental clinique established in that town. The great interest taken in Switzerland in school hygiene is evidenced by the fact that the Annals for 1907 contain 23 articles and lectures on the most varied subjects, including a lengthy report on the conference held in August in London, and that the Annals have now increased to a volume of over 600 pages.

Zürich, May 31st.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Optic Neuritis and the Inducement of Premature Labour.

Dr. Meissner at a recent meeting of the Gesellschaft der Aerzte brought up an important subject for discussion. A woman, aged 34 years, was three months advanced in her fifth pregnancy. She had had syphilis six years before and suffered from optic neuritis, which ultimately yielded to a combined iodide and mercury treatment. Two years later she became pregnant for the first time and her sight became very bad but after the birth of a healthy baby it improved, without, however, regaining its former acuity. Since then she had been pregnant three times and always when in this condition her eyes became worse, so that now she applied to the hospital to have premature labour induced in order to save her eyesight. She also complained that during the catamenia her sight generally was worse than at other times. The ophthalmic examination showed distinct signs of optic neuritis, some irregular astigmatism, and also concentric diminution of the field of vision; red was the only colour which she could recognise. The question for consideration was whether there was any connexion between the ocular disturbance and the pregnancy. Was the inducement of premature labour justified because of the possibility of permanent injury to the sight being caused by allowing pregnancy to progress to full term? The supposition that pregnancy alone was responsible for the neuritis must be repudiated, for the presence of syphilis had undoubtedly a great deal to do with it. Nevertheless, the treatment with iodide and mercury, to which the patient had been subjected for four weeks, had not done her any good, and the concentric diminution of the field of vision had increased. But this rather pointed to hysteria, not to an organic lesion. Therefore, in Dr. Meissner's opinion, one was justified in waiting before resorting to the operative measure. In the ensuing discussion it was pointed out by Professor Hochenegg that he had once observed in a pregnant woman an increase in size of the hypophysis cerebri, causing optic neuritis by pressure. This disappeared after the birth of the child, but left always a weakened eyesight. Professor Reuss had seen a similar case in which the patient had given birth to 16 children. She suffered during each pregnancy from bad sight, but the condition remained stationary after that, and when she died, 71 years old, she was not blind. Anyhow, such occurrences are not very frequent, otherwise gynæcologists would have reported them. It was decided in this particular case to wait for further development before complying with the patient's wish that labour should be induced.

Professor Toldt's Resignation.

At the end of this term Professor Toldt, the well-known anatomist, will resign his chair as director of the second anatomical institute in Vienna. He could teach for another two years, being only 68 years old, and 70 being the age limit, but he is overburdened with his scientific work, of these places is hardly known, panic having seized many of the miners who fly from one village to another. Many of the collieries have a scanty supply of water and the excessively dry season has dried up the wells. In ordinary circumstances the coolies are well housed and well looked after from a sanitary point of view, but on an occasion such as this the men become scared and leave their sick and dying friends and relatives without hesitation. It is even reported that in those parts where European control is less evident dead bodies have been found lying in dry nullahs and fields left to be devoured by vultures and dogs. In Calcutta the mortality from cholera has been rising rapidly week by week since the Great "Ardhodoya" Festival of Feb. 2nd. In the week ending Feb. 1st there were 24 deaths, in that ending Feb. 8th there were 104 deaths, and the numbers rose gradually until in the week ending April 25th there were 302 deaths. The native quarters, especially the northern part of the city, have been chiefly affected, but several Europeans have been attacked and 11 European deaths have been reported up to date. The prolonged dry weather has been accompanied with an unusually foul state of the river Hooghly and it is to this that the severity of the outbreak must be attributed.

"*Epidemic Dropsy.*"

The outbreak of "epidemic dropsy" which has affected Calcutta for the past eight months seems to be practically over. It has been much more severe than previous outbreaks and many of the cases were quite indistinguishable from beri-beri. Opinion in some quarters has changed with regard to the nature of this disease and there are several who now look upon it as an acute specific contagious disease probably identical with beri-beri. One observer puts the incubation stage at three days. There have been some small isolated outbreaks in other parts of Bengal, but these have been for the most part of a mild character.

Rinderpest in Karachi.

The manner in which the owners of cattle in Karachi, including even the superstitious milkmen, have come forward to secure immunity against rinderpest for their animals may be taken as another hopeful sign that the old objections to inoculation are dying out in the minds of the people. The struggle of medical science in India to overcome the prejudices of the people against inoculation has been a long and a difficult one, but now that a good start has been made with the help of the serum manufactured in Bombay the ravages of the plague should be checked materially.

Health of British Troops in India.

Attention has already been drawn to the highly efficient state of the army in India from a health point of view. When Surgeon-General Sir Thomas J. Gallwey, C.B., K.C.M.G., was specially selected to be principal medical officer of His Majesty's forces serving in India in January, 1902, he initiated what has since been proved to be the most thorough and practical reorganisation of the medical services of the army. His introduction of widespread sanitary improvements in barracks and cantonments has year by year improved the health efficiency of the army. Attention was also directed to enteric fever, malaria, and certain other diseases, each being taken in detail and met with the whole machinery of modern preventive medicine and treatment. Now that the complete statistics for 1907 are available it is satisfactory to observe that the admission-rate to hospital and the death-rate are the lowest on record for India, the former being 855·4 and the latter 8·15 per 1000, as compared with 871 and 10·43 per 1000 respectively in 1906. As regards invalids sent from India to the United Kingdom the figures are still more encouraging. In the trooping season of 1906-07 there were sent under this category to England 2015 sick and 75 insane; during the trooping season of 1907-08 just closed the figures were 1097 sick and 68 insane, or a decrease of 1015, which represents more than the strength of one complete regiment of infantry. There were also 126 fewer women sent home as invalids, and as their husbands have usually to accompany them the net gain to the army for all invaliding out of the country has been over 1100 men. An experiment was tried during the cold weather (trooping season) of sending weakly men to the hills instead of invaliding them to England. The hill stations in India possess an unrivalled climate in the winter months for many kinds of disease, the air being dry and extremely bracing, and the results of employing certain selected hill-stations as winter sanatoriums has been on the whole most satisfactory.

Building Regulations for Calcutta.

The building regulations for the city of Calcutta have been the cause of a great deal of trouble for some time past, and two or three attempts have been made to improve them. Unfortunately, and for no definite reason except economy, the post of city architect was abolished last year and the duties have since been placed in the hands of the district engineers. Apart, however, from this retrograde policy the building regulations are very faulty and permit the construction of most undesirable dwellings. The Government has at last appointed a special committee to amend these regulations. It is to be hoped that the post of city architect will be reinstituted, as even if all the district engineers were fitted for this work their time is so occupied with other duties that they cannot properly attend to it.

Death of Lieutenant-Colonel F. S. Peck, I.M.S.

Much regret has been felt in Calcutta and also in Behar at the death of Colonel F. S. Peck, I.M.S. During his leave in England last summer he met with a serious accident, being being knocked down by a train at Sheringham while he was crossing the railway in going the round of the golf links. He had a marvellous escape, as the whole train passed over him, but he sustained severe injuries to the head. He recovered sufficiently to return to India early in November, but his health broke down in Calcutta and he was invalided home last month. Colonel Peck was not only a distinguished surgeon but a keen polo and racquet player and in Behar he was emphatically the right man in the right place.

May 14th.

Obituary.

JOHN JAMES RIDGE, M.D., M.D. (STATE MEDICINE), B.A., B.S., B SC. LOND., M.R.C.S. ENG., &C.

WE regret to announce the death of Dr. John James Ridge of Carlton House, Enfield, Middlesex. For the last year or two Dr. Ridge had, now and again, seemed to feel the stress of his practice and of the much outside work which he was doing, but hitherto after a short rest and a walking tour in this country or abroad his health and energy have appeared to his outside friends thoroughly to be restored. Some months ago, however, Dr. Ridge asked the council of the British Medical Temperance Association to relieve him of the duties of secretary, and to this request that body felt compelled to accede. At the meeting at which this resignation was accepted Dr. Ridge was nominated a member of council and vice-president of the association. Dr. Ridge was then confined to bed. Afterwards for some time his condition appeared to improve but a sudden change for the worse supervened, and although everything was done that skill and affection could devise the end came on Monday, May 25th.

In Dr. Ridge's strenuous and unselfish life many men have found an example and incentive such as are offered by the lives of few men, even in our profession. Born at Gravesend, of which borough his father was twice mayor, John James Ridge was educated at the City of London School where he took the Tite scholarship at St. Thomas's Hospital. Entering this hospital in 1864 he carried on his studies for his degrees in arts and science and for his medical diploma and degree at the same time. At the age of 19 he graduated B.Sc., in the following year B.A., and in the year following that he obtained the diplomas L.R.C.P. Lond. and M.R.C.S. Eng., and the degrees M.B., B.S., in the University of London, being awarded the University scholarship in surgery, with scholarship and gold medal. In 1869, the year after taking his M.B. degree, Dr. Ridge graduated M.D. and then again in 1891 took the M.D. degree in State Medicine. After holding the appointment of house surgeon at St. Thomas's Hospital Dr. Ridge entered on private practice at Clapham where he made a number of life-long friends. He there commenced that work with which his name will ever be associated, and, with Mr. J. T. Rae, engaged in temperance work amongst the children of the district, working at Grafton-square Congregational Church, in connexion with which a Band of Hope was carried on. The opportunity of taking up the practice of the late Dr. Godfrey soon presented itself and Dr. Ridge left his Clapham practice able, on ground of our studies, to judge and recognise the effects of alcoholic beverages, consider that it is definitely proved that all alcoholic beverages are entirely superfluous and harmful in a high degree, and that all diseases arising from the consumption of alcohol can and must be exterminated. *Before all things we must teach the rising generation and educate it by our own example in abstaining from alcoholic beverages, besides defending them by legislation.* We consider this action to be necessary for the health of mankind, and to promote and insure the happiness and well-being of the people.—(Signed) Dr. Holitser of Pirkenhammer, Dr. Santesson of Stockholm, Dr. Ridge of London, Dr. Laitinen of Helsingfors, Dr. Olrik of Frederiksvaerk, Dr. Stein of Budapest, Dr. Vogt of Christiania.

June 8th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Regulation of Medical Experts.

THE recent discreditable exhibitions of medical expert testimony in the courts of New York have led to a conference of a committee of the Academy of Medicine with a similar committee of the Bar Association for the purpose of devising a system of employment of medical experts which should render their testimony non-partisan and thoroughly trustworthy. The following scheme is proposed. At any time in the pendency of any civil proceeding in any court in which any medical or surgical question is likely to be material, the court or any justice thereof may, or at the request of either party shall, appoint from the list made up as hereinafter provided, one or more persons learned in the science of medicine and surgery, and of not less than seven years' actual practice, as official experts, who shall investigate the facts of the case and give their opinion upon any such question arising in such proceeding, and make written report thereof to the court. The list of names of members of the medical profession, qualified as experts, and recommended to the courts, shall be made by the Academy of Medicine for the courts of New York City and by the Medical Society of the State of New York for the courts in the rural districts. When an expert is summoned in a case by order of the court he shall forthwith make such examination of the case as in his judgment may be necessary and practicable and make written report thereof to the court. Such report shall be open to the inspection of either party and may be read in evidence, and such expert may be called as a witness by either party at the trial. The measure provides that either party at the trial may call other expert witnesses, but at his own expense.

Paresis a Germ Disease.

At the recent annual meeting of the American Medico-Psychological Association Dr. O'Brien, of the Massillon State Hospital, Ohio, made the announcement that at the laboratory of that institution the germ of paresis has been discovered and its effects have been demonstrated. He stated that while in an experimental stage sufficient tests had been made to show that paresis is curable and that he had specific cases to point to as definite results. Dr. O'Brien reported several cases of cure and referred to several asylum superintendents who had used the remedy with favourable results. He began his experiments by taking serum from the spinal canal of living patients and experimenting with it on dogs, rabbits, and rats. The report was received with much incredulity and needs authentic verification.

An Association of Milk Commissions.

A permanent organisation known as the "American Association of Medical Milk Commissions" has been formed. The purpose of the association is to federate and to bring into one compact association the medical milk commissions of the United States; to exchange views and to adopt uniform methods of procedure in the work of securing to communities pure milk; to fix chemical and bacteriological standards; to determine the scope of veterinary inspections; and to foster and to encourage the establishment of medical milk commissions throughout the country. It is believed that once established each milk commission would become a potent factor in the community and would stimulate the efforts of local boards of health and thus eventually raise the quality of the total supply.

Abolition of the Tuberculin Test for Tuberculosis among Cattle.

The enormous destruction of cattle due to the use of the tuberculin test has led to universal protests of farmers against its exclusive use in the diagnosis of tuberculosis in their herds. The result is a radical reform on the part of the Superintendent of Agriculture of New York and some other States in the treatment of cattle. The changed methods will prove of immense importance not only in saving cattle but in protecting the people from the use of diseased milk and meats. The superintendent proposes to apply the usual physical tests in diagnosis and to use tuberculin in doubtful cases only. The remedies employed are to be strictly hygienic and not the slaughter of the affected cattle, except in extreme cases. The affected cattle are to be carefully isolated from the herd, to be properly fed and housed in clean, well-ventilated stables, or pastured on elevated grounds. In general cattle suffering from tuberculosis are to be treated on the same principles as human beings suffering from that disease are treated. Inspectors of herds are to be appointed who are skilled in the diagnosis of tuberculosis in cattle; the farmers are to organise for conference; and stations are to be created where farmers can obtain the advice and aid of the State Inspecting Corps at all times. The new *régime* of dealing with bovine tuberculosis is very popular with farmers and there is satisfactory proof that the sanitation of dairies is to be carried to a high degree of perfection.

The Philippine Islands Medical Association.

This association is composed largely of United States army officers serving in those islands. It recently held its fifth annual meeting in the rooms of the Philippine Medical College at Manila. The sessions were well attended and among the invited guests were the health officer of the British colony of Hong Kong, Dr. Francis W. Clark; Professor Kitajima of the Infectious Disease Institute, Japan; and Dr. Cheng Hao, delegate from His Imperial Chinese Majesty's Government. A large number of interesting papers were read, the subjects being observations, investigations, and experiences relating to the diseases of the islands. The value of this association in a better understanding of the diseases of that country will prove incalculable. One of the papers on the recent epidemics of cholera by Dr. Heiser, director of health for the Philippine Islands, will prove of great service to the local authorities in future efforts to prevent the prevalence of that destructive pestilence. He states that cholera in the provinces always has its origin in Manila; that the cholera organism is continuously present in some form in the sewer system of Manila; that this organism is conveyed, directly or indirectly, from the sewers to easily contaminated articles of food or drink by cockroaches, flies, water-bugs, and other vermin; and that the disease extends from Manila by means of contaminated foods. By thus localising the germ of the epidemic in the sewers he makes plain the remedy to be applied.

The Cause of Milk sickness or "Trembles."

Much was written about a disease among pioneers in the settlement of this country which was attributed to the milk of cows which were affected by a disease called the "trembles" from one of its most prominent symptoms. When the human subject was seized with this disease it was called "milk-sickness," as it was supposed to be derived from milk from the diseased cow or the meat taken after the animal was slaughtered. The disease seemed to be confined to certain localities as along some rivers and streams. It has never been known east of the Alleghany mountains. Recently it was found to be present in the valley of the Pecos river, New Mexico, over 1000 miles from its previous locality. By the aid of a grant from the Institute for Infectious Diseases, Chicago, Professor Edwin O. Jordan, of the bacteriological department of Chicago University, and his assistant visited the locality for the purpose of investigating the cause of this peculiar disease. They were able to carry on a series of studies which resulted in the discovery of what they regard as the germ and this they have termed "B. lactimorbi." The disease produces degenerative changes in the myocardium, the liver, and kidneys, mostly of a fatty nature.

Cholera in Lower Bengal.

THE outbreak of cholera in Lower Bengal has assumed large proportions. Not only has Calcutta been attacked but the Jherria coal-fields with their large populations of coolies have been seriously affected. The actual mortality in some architecture and marine engineering at the University of Tokio, Japan. There are 24 grandchildren and nine great grandchildren surviving. The interment took place at Nunhead Cemetery on June 3rd and was attended by numerous relatives and friends, and representatives from all the various bodies with which he had been connected.

WILLIAM KING BULLMORE, M.D. ST. AND., M.R.C.S. ENG., L.S.A.

DR. W. K. Bullmore, the eldest son of the late Dr. F. C. Bullmore, died at his residence at Falmouth on June 4th, aged 74 years. Dr. Bullmore received his early education at Falmouth Grammar School and afterwards entered at Middlesex Hospital. In 1857 he became a Member of the Royal College of Surgeons of England and a Licentiate of the Society of Apothecaries. In 1859 he took the M.D. of St. Andrews and afterwards returned to Falmouth where he commenced practice by assisting his father. The deceased, who was a Fellow of the Royal Institute of Public Health and a member of the British Balneological and Climatological Society, had held several public appointments, among them being surgeon in charge of troops at Pendennis Castle and medical officer of health of Falmouth and Truro port sanitary authority. He was surgeon-major in the 1st Cornwall Volunteer Artillery. Dr. Bullmore was a keen sportsman, a yachtsman, and an ornithologist, his collection of Cornish birds being a very fine one. He was the author of "Vertebrata in Cornwall," for which book he received the bronze medal of the Royal Cornwall Polytechnic Society in 1866.

DAVID THOMPSON, L.R.C.P., L.R.C.S. EDIN., L.S.A., J.P.,

CORONER FOR THE COUNTY OF CORNWALL.

Mr. David Thompson died at his residence, "Dunstowe," Launceston, Cornwall, on May 27th, in his seventy-seventh year, from syncope. The deceased, who at one time had a very extensive practice at Launceston, was appointed county coroner 19 years ago. He was also a very enthusiastic Volunteer, having joined in 1859, and at the time of his resignation he was brigade-surgeon-lieutenant-colonel of the Plymouth Brigade. He was a county and borough magistrate. Mr. Thompson was for many years an alderman of Launceston borough council, and on one occasion filled the mayoral chair. He celebrated his golden wedding on Feb. 7th, 1906. Mr. Thompson was most popular in Launceston and was highly esteemed. He leaves a widow and one son and two daughters, with whom much sympathy is felt.

The funeral took place at Launceston on June 5th. It was attended by the mayor, members of the corporation, borough officials, members of the local lodge of Freemasons, and others.

SURGEON-GENERAL SIR JAMES ARTHUR HANBURY, K.C.B., M.B. DUB., F.R.C.S. ENG. & IREL. (HON.), A.M.S. (RETIRED).

THE death occurred at Bournemouth on June 2nd, at the age of 76 years, of Surgeon-General Sir James Arthur Hanbury, K.C.B., who served in the Afghan war of 1878–80 and took part with the expedition into the Bazar Valley, being mentioned in despatches. He also accompanied Sir Frederick Roberts in the march to Candahar and was present at the battle of Candahar. Besides being mentioned in despatches he received the C.B., and the medal with clasp, and bronze decoration. As principal medical officer he served in the Egyptian war of 1882 and was present at the battle of Tel-el-Kebir. Twice mentioned in despatches, he was awarded the K.C.B. and also received the medal with clasp, the Second Class of the Medjidieh, and the Khedive's star. Sir James Hanbury graduated M.B. of Dublin in 1853; he was elected (as a member of 20 years' standing) F.R.C.S. Eng. in 1887 and honorary F.R.C.S. Irel. in 1883. The funeral took place at Bournemouth on June 7th.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. William Wright, formerly professor of materia medica in the McGill University, Montreal.—Dr. W. H. Earles, professor of surgery in the Milwaukee Medical College.—Dr. Gigli of Florence, whose name is known in connexion with the operation of hebotomy.

Medical News.

TRINITY COLLEGE, DUBLIN.—At examinations held in Trinity term the following obtained the Diploma in Public Health:—

Part I.—George E. Nesbitt, Thomas O. Graham, Richard G. S. Gregg, and William R. Galwey.

Part II.—George E. Nesbitt, John A. Pringle, William R. Galwey, and Thomas O. Graham.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Eduard Sonnenburg has been promoted to an honorary Professorship of Surgery. Dr. Helbing has been appointed to take charge of the University Policlinic for Orthopædic Surgery. Dr. Max Lewandowsky, *privat docent* of Physiology, has been granted the title of Professor. The title of Professor has been conferred on two private practitioners who are unconnected with the teaching staff of the University, viz.: Dr. Oskar Zeller and Dr. Alexander Czempin.—*Ghent:* Dr. de Nobele and Dr. Gommaerts have been appointed Instructors in the newly established Institute of Physio-therapeutics.—*Göttingen:* The lectures on Pharmacology will be delivered during the present semester by Professor Schwenkenbecher of the Medical Policlinic.—*Kharkoff:* Dr. Panski has been appointed to the chair of Clinical Surgery.—*Lemberg:* Dr. Jurasz has been appointed Extraordinary Professor of Laryngology.—*Moscow:* Mdlle. Viera Danchakoffa has been recognised as *privat-docentin* of Histology, being the first lady recognised by any Russian University.—*Munich:* Dr. Ibrahim of Cairo and Heidelberg has been recognised as *privat docent* of Children's Diseases.—*Naples:* Dr. Clemente Romano has been appointed Extraordinary Professor of Orthopædic Surgery.—*Pavia:* Dr. Aldo Cerneri has been recognised as *privat docent* of External Pathology. Dr. Stefano Lodovico D'Este has been recognised as *privat docent* of Surgery.—*Pisa:* Dr. Amilcare Panella has been recognised as *privat-docent* of Physiology. Dr. Vittorio Grazzi has been appointed Extraordinary Professor of Otology and Laryngology.—*Rio de Janeiro:* Dr. Prowazek and Dr. Giemsa of Hamburg have been engaged by the Brazilian Government for duty at the Hygienic Institute.

THE UNIVERSITY OF LONDON AND KING'S COLLEGE, LONDON.—The Bill transferring to the University of London the powers and duties of King's College, London, "in relation to instruction of a University standard in subjects comprised within the Faculties in the University other than the Faculty of Theology," was considered recently by the Select Committee of the House of Commons on Unopposed Bills. Sir Arthur Rücker, principal of the University of London, and the Rev. Dr. Headlam, principal of King's College, joined the committee in considering the report of the Attorney-General on the Bill, and after some debate it was decided to impose a conscience clause for the protection of students attending King's College. Sir Arthur Rücker having given formal proof of the allegations in the preamble the committee passed the Bill and ordered it to be reported with amendments for third reading.

MOTOR ACCIDENTS IN THE EAST-END OF LONDON.—At the last meeting of the Stepney borough council held on June 3rd the following resolution was ordered to be sent to the Home Secretary and to the Commissioner of Police: "That, owing to the increasing number of accidents caused by motor traffic in the county of London, the maximum speed of all motor and other vehicles should be reduced at most to ten miles an hour, and owing to the serious annoyance and discomfort caused by excessive noise, vibration, &c., the police should be granted enlarged powers to control this class of traffic." The action of the Stepney borough council has no doubt been determined by the unfortunate accident which happened a few days ago when a child, aged three years, was killed in a motor omnibus accident. Eye-witnesses, who included a policeman, stated at the inquest that the child was one of three who attempted to cross the road when the omnibus was about to pass. When they saw the omnibus coming towards them all three ran in different directions. The driver gave ample warning, did all he could to avoid the accident, and succeeded in keeping clear of two of the children, but the third was caught by the front of the vehicle and killed. The omnibus was travelling at a speed of about six to eight miles an hour. The jury returned a verdict of and settled down at Enfield where he soon acquired the confidence and affection of a large circle of patients. Later he became medical officer of health of the Enfield urban district council and medical superintendent of the Enfield and Edmonton joint isolation hospital. His reports sent out from this latter hospital hold an important place in statistical literature. One of Dr. Ridge's chief interests, however, was the London Temperance Hospital in Hampstead-road. The first patient was admitted to this hospital on Oct. 6th, 1873, Dr. James Edmunds and Dr. Ridge then constituting the staff. Dr. Ridge was physician to the hospital for 25 years and took a very prominent part in determining the policy and carrying on the organisation and development of the institution, so that when he retired its success was assured. The work of this hospital still continues to increase in importance and its staff in strength.

Dr. Ridge was one of the finest of a fine type, the English practitioner of medicine. A sound and sympathetic physician, a skilled surgeon, a Christian gentleman, keenly interested in the welfare of his fellows, his name will be remembered not merely in Enfield and for his distinctly medical work but throughout the country, nay throughout the civilised world, for his enthusiastic and rational advocacy of the temperance question. Associated with Sir G. Burrows, Dr. James Edmunds, and the late Sir Benjamin Ward Richardson in the formation of the British Medical Temperance Association, Dr. Ridge acted as secretary of that association up to within a very short time of his death. He was ever on the outlook for the best means of advancing its work and one of the last efforts which he made was to organise a number of local centres in order that the interest of the members should be as concentrated as possible.

The *British Medical Temperance Review*, the direct descendant of the *Medical Pioneer*, which he edited, and the *Medical Temperance Journal*, to which he contributed, was his constant care. No trouble was too great if good articles could thereby be obtained and good reports of meetings and trustworthy abstracts of scientific papers offered to the readers of the *Review*. The association and the *Review* have been made models on which similar societies and papers have been founded in foreign countries and in our colonies and Dr. Ridge has been the moving spirit in both. No man in this country was better known or more thoroughly esteemed and admired by medical abstainers abroad than was Dr. Ridge, and it was but fitting that when it came to the election of a president for the New International Medical Temperance Association, founded in Stockholm last July, the choice of the association should fall on Dr. Ridge, a nomination that was carried with acclamation. Although engaged in active practice Dr. Ridge always seemed to be able to find time to take part in any public movement that stirred his imagination or roused his sympathy. Politics, religion, social movements, art, and literature all had their attractions for him; indeed, no one could be with him for even a short time without feeling that every thought and action of the man had its origin in his religion and its direction in his culture. A man of broad sympathies, grand courage, strict integrity, and very human, he gradually but surely gained the confidence and affection of those with whom he came into close touch. A certain shyness and nervousness of manner were sometimes misleading to those who met him but casually. These, however, soon disappeared as acquaintance improved. His strong convictions and his cold logical manner of putting his case naturally made him some enemies, but even those who did not agree with him ultimately came to respect both the man and his convictions.

At the funeral service at Christ Church, Enfield, the note struck throughout was one of triumph. The many friends from all ranks who came to pay their last respects to the "dear doctor" grieved at their loss but rejoiced that they had been privileged to enjoy his friendship.

The following resolution was passed at a meeting of the executive committee of the National Temperance League held on May 28th:—

That the Executive Committee of the National Temperance League have heard with deep regret of the death of Dr. J. J. Ridge, who has been a Vice-President of the League for over 16 years. They desire to place on record their high appreciation of the valuable services which Dr. Ridge has unostentatiously rendered to the temperance cause. first by his active coöperation with the League in its early efforts to influence the medical profession and with the late secretary of the League in his editing of the *Medical Temperance Journal* for 20 years; and secondly by his devoted labours as honorary secretary of the British Medical Temperance Association, of which he was the founder.

PRIOR PURVIS, M.D.LOND., M.R.C.S.ENG., L.S.A.

WE have already recorded the death of Dr. Prior Purvis of Blackheath, the doyen of the University of London, in his ninety-sixth year. In May, 1907, he began to suffer from retention of urine due to an enlarged prostate gland, and as at his age it was not deemed advisable to operate the obstruction gradually increased, requiring the frequent use of the catheter. A fortnight before his death he had severe prostatic hæmorrhage which lasted two or three days, and although this was controlled it left him so enfeebled that he sank and died on May 29th.

Prior Purvis was born at Greenwich on Oct. 31st, 1812. He was educated at "Stockers," at the time a well-known school in Poplar. At the age of 15 years he was apprenticed to Mr. Cornwall, a surgeon in large practice at Fairford, Gloucestershire, and he was very fond of telling tales of those days and how the country labourers would come in crowds in the spring and fall to be "blooded," and how at those times the surgery would resemble a shambles. He was one of those who believed in the change in type of disease, as he was sure that then bleeding did good, whereas now he was equally convinced that it would do nothing but harm. He was also one of those who thought that it was a pity to have given up apprenticeship and used to say that in the old days the medical student learnt his profession before he came to London, but now he enters the hospital entirely ignorant, as a rule, of professional work. In London Purvis studied at the Borough Schools (combined Guy's and St. Thomas's) and in due course took his L.S.A. in 1834 and M.R.C.S.Eng. in 1835; in 1839 he passed the M.B. at the newly established University of London and proceeded to the M.D. in 1842, being amongst the first batch who presented themselves for that degree. He settled in his native town of Greenwich, afterwards removing to Blackheath, and soon obtained a large practice. He took an active part in public works to which he devoted a very considerable portion of his time, being a member of the old vestry, where he was foremost in promoting new projects such as the establishment of the baths and washhouses, under the Baths and Washhouses Act. He was one of the founders of the Mechanics' Institute, delivering some of the earlier lectures himself; he was made acting trustee and treasurer from the first and retained the position until the affairs of the lecture hall, as it was then called, were wound up and the building was sold to the borough council in 1900 to become the Borough Hall. He was also one of the founders and for many years chairman of the Industrial Permanent Benefit Building Society, Greenwich, holding this position at his death; and he was one of the original governors of the Roan School and a Commissioner of Taxes. A Liberal in politics and of a somewhat combative nature he threw himself into all the great political questions of the day, notably that of the admission of the Jews into Parliament. He strongly supported Alderman (afterwards Sir David) Salomons in his Parliamentary candidature and for years was chairman of his Parliamentary committee. The same liberal bent of mind caused him strongly to support the admission of women into the ranks of the medical profession and several of the present medical women have frequently expressed their gratitude to him for his efficient help in their early struggles.

Dr. Purvis took a leading part in the establishment of the West Kent Medico-Chirurgical Society, being its treasurer from its initiation in 1856 till increasing years and infirmity caused him to resign in 1897. On his resignation the members presented him with a very handsome china clock and pair of vases. Two years before his resignation an oration in his honour was instituted, to be delivered annually at the meeting in December by some distinguished member of the profession, to be called the Purvis Oration. Since then the orators have been Mr. Arthur Durham, Dr. John Curnow, Professor G. Sims Woodhead, Dr. A. E. Sansom, Sir Victor Horsley, Dr. Vivian Poore, Dr. J. F. Goodhart, Mr. Anthony A. Bowlby, Dr. J. Rose Bradford, Mr. J. Bland-Sutton, Mr. Jonathan Hutchinson, Mr. A. W. Mayo Robson, and Dr. J. S. Risien Russell. He was also a vice-president of the Medical Defence Union.

Dr. Purvis married in 1840 and celebrated his diamond wedding in 1900; his wife predeceased him, dying in July, 1907. They had ten children, seven of whom survive (two sons and five daughters). The eldest son, John Prior Purvis, has been his partner in the practice for 40 years; his other son, Frank Prior Purvis, is professor of naval *such as that of a works doctor or medical officer of a workmen's club or any regular employment from an accident insurance company, which might cause him to be regarded as representing the interests of any party in cases arising under the* Act. The case of certifying surgeons who are primarily appointed for duties under the Factory Act stands on a somewhat different footing and no similar condition is imposed. I have made inquiries, however, of the certifying surgeons in the Potteries district and am informed by them that they do not hold appointments from the Potteries Insurance Company and do not investigate on behalf of the company cases of suspected lead poisoning or attend the directors' meetings. It appears that in pursuance of an arrangement made before the passing of the Workmen's Compensation Act, 1906, in connexion with the scheme of insurance in the special rules the certifying surgeons have made weekly examinations of operators who had been suspended by them under the rules and furnished the worker with a certificate of his condition. There have been very few appeals so far against the determination of certifying surgeons—in the first nine months ten, of which two only referred to lead cases—and I cannot say whether the certifying surgeon has appeared before the referee or not. The certificate of the surgeon which is appealed against has, under the Secretary of State's rules, to be submitted to the referee, who is also required to consider any statements made or submitted by either party. If either party wishes to submit any explanation by the certifying surgeon of the grounds for his decision I do not think that could properly be prevented. As regards the point raised by my right hon. friend in the penultimate sentence of the question, this is already provided for, as above stated, in the case of medical referees, and as regards certifying surgeons it has not escaped my consideration. It would not, however, be possible to lay down a strict rule because in industrial districts it is often difficult to find a well-qualified medical man who does not hold some appointment from employers or associations of workpeople. The question would be outside the scope of the reference to the Lead Committee, but I shall be happy to inquire into any case of grievance which may have come to the notice of my right hon. friend.

The Public Health (Regulations as to Food) Act.

Mr. Morton asked the President of the Local Government Board to state when it was proposed to issue the regulations under the Public Health (Regulations as to Food) Act.—Mr. Burns: I hope shortly.

THURSDAY, JUNE 4TH.

The Regulation of the Milk-supply.

Mr. Snowden asked the President of the Local Government Board whether he was yet in a position to say when he hoped to introduce the promised Bill for the better regulation of the milk-supply.—Mr. Burns replied: I cannot at present fix a date for this purpose.

Mr. Watt also asked the Secretary for Scotland whether the Bill dealing with milk, which was to be introduced for England and Wales by the Government, would apply to Scotland.—Mr. Sinclair said: The answer is in the negative. I may add that legislation for Scotland, which is under separate administration, is under consideration.

The Inebriates Acts in Scotland.

Mr. Watt asked the Secretary for Scotland whether it was his intention to appoint a Scottish Commission to inquire into the working in Scotland of the Inebriates Acts; and, if so, when he would make the appointments.—Mr. Sinclair replied: The matter is engaging my close attention and I hope to be able to make an announcement at an early date.

BOOKS, ETC., RECEIVED.

Baillière, Tindall, and Cox, 8, Henrietta street, Covent Garden, London, W.C.

A Manual of Diseases of the Eye. By Charles H. May, M.D., New York, Chief of the Eye Clinic, Columbia University, New York, 1890-1903; Ophthalmic Surgeon to the City Hospitals, the French Hospital, the Red Cross Hospital, and the Mount Sinai Hospital, New York; and Claud Worth, F.R.C.S. Eng., Consulting Ophthalmic Surgeon to the West Ham and East London Hospital, Assistant Surgeon to the Royal London Ophthalmic Hospital, Moorfields. Second edition. Price 10s. 6d. net.

Physical Signs of Diseases of the Thorax and Abdomen. By James E. H. Sawyer, M.A., M.D. Oxon., M.R.C.P. Lond., Casualty Assistant Physician and Medical Registrar, the General Hospital, and Physician to Out-patients, the Children's Hospital, Birmingham. Price 5s. net.

The Treatment of Gonorrhœa in the Male. By Charles Leedham-Green, M.B., F.R.C.S., Surgeon to the Queen's Hospital, Birmingham, Surgeon to the Birmingham and Midland Hospital for Children, Consulting Surgeon to the Birmingham General Dispensary. Second edition. Price 5s. net.

Butterworth and Co., 11 and 12, Bell Yard, Temple Bar, London.

The Diseases of Workmen. By T. Luson, M.D., and R. Hyde, M.R.C.S. With an Introduction by His Honour Judge Ruegg, K.C. Price not stated.

Cassell and Company, Limited, London, Paris, New York, Toronto, and Melbourne.

Clinical Methods. A Guide to the Practical Study of Medicine. By Robert Hutchison, M.D., F.R.C.P., Physician to the London Hospital, and Assistant Physician to the Hospital for Sick Children, Great Ormond-street; and Harry Rainy, M.D., F.R.C.P. Ed., F.R.S.E., Assistant Physician to the Royal Infirmary, Edinburgh. Fourth edition, thoroughly revised. Price 10s. 6d.

Chemist and Druggist, The, Offices of, 42, Cannon-street, London, E.C.

The Art of Dispensing. Eighth edition (revised and enlarged). By Peter MacEwan, F.C.S., Pharmaceutical Chemist, Editor of "The Chemist and Druggist." Price not stated.

Churchill, J. and A., 7, Great Marlborough-street, London, W.

Uric Acid as a Factor in the Causation of Disease. By Alexander Haig, M.A., M.D. Oxon., F.R.C.P., Physician to the Metropolitan Hospital and the Royal Hospital for Children and Women; late Casualty Physician to St. Bartholomew's Hospital. Seventh edition. Price 14s. net.

Fischer, Gustav, Jena.

Die Spezielle Chirurgie in 60 Vorlesungen. Kurzgefasstes Lehrbuch für Aerzte und Studierende. Von Dr. Edmund Leser, Professor an der Universität in Halle, Mitglied der Kaiserlichen Leopoldino-Carolinischen Deutschen Akademie der Naturforscher. Achte vermehrte und verbesserte Auflage. Price M. 24; geb., M.26.50.

Di una Forma di Splenoadenopatia Cronica dovuta ad un Bacillo Sottile. Studio clinico, batteriologico e sperimentale del Dott. Guido Ferrarini, Aiuto e libero docente. Price not stated.

Treat, E. B., and Co., 241-243, West 23rd-street, New York.

Transactions of the American Pediatric Society. Nineteenth Session held at the Arlington Hotel, Washington, D.C., on May 7th, 8th, and 9th, 1907. Edited by Linnæus Edford La Fetra, M.D. Volume XIX. Reprinted from Archives of Pediatrics, 1907-1908. Price not stated.

"Accidental death," exonerating the driver of the omnibus from blame. Local feeling has, however, run so high that a riotous demonstration against motor omnibuses has been made in Mile End-road.

GOLF: CHURCH *v.* MEDICINE.—An interesting match was played at Bristol on June 3rd between local golfers representing the clergy of the Church of England and members of the medical profession. The match resulted in a win for the latter by 8½ points to 4½.

THE summer dinner of the West African Medical Staff will take place on June 22nd next at the New Gaiety Restaurant, Strand, London. Any medical officers who have not yet received an intimation should communicate without delay with Dr. W. T. Prout, 78, Rodney-street, Liverpool.

DONATIONS AND BEQUESTS.—By the will of Mr. F. A. Smith of Ashby-de-la-Zouch the Nottingham General Hospital will receive £1000. Mr. R. H. Wood of Sidmouth and Pantglas bequeathed £1000 to the West of England Eye Infirmary at Exeter for the endowment fund and a like sum to the Devon and Exeter Hospital. Miss E. Henry has given a donation of £1000 to the Northampton Hospital as a memorial to her brother, the late Mr. W. J. Henry.

FRIEDENHEIM HOSPITAL.—The annual meeting of the friends and supporters of the Friedenheim Hospital (Home of Peace for the Dying) will take place to-day (Saturday) at 3.15 P.M., in the Hampstead Conservatoire, Swiss Cottage, N.W. Princess Louise Augusta of Schleswig-Holstein will preside and will be supported, among others, by the Duchess of Somerset, Mr. John Langton (chairman), the Rev. Prebendary Webb-Peploe, Mr. A. Pearce Gould, Dr. P. J. F. Lush, Dr. A. T. Schofield, and the Rev. H. Summerhayes.

WORTHING HOSPITAL.—A bazaar has just been held at Worthing in connexion with the local hospital extension scheme. Constant enlargement has been necessary to cope with the work which has fallen to its lot. About 200 in-patients and 2500 out-patients, in addition to many minor cases, are received annually. The work of raising the sum required—from £1600 to £2000—has been a special effort of the mayor, Alderman F. C. Linfield. On one day the bazaar was opened by His Highness the Jam Saheb of Navanagar, who gave the mayor a cheque for 20 guineas.

LITERARY INTELLIGENCE.—His Majesty the King, who has always shown a keen interest in the housing conditions of the people and who in 1884 and 1885 as Prince of Wales sat on a Royal Commission to inquire into the housing conditions of the working classes, under the presidency of Sir Charles Dilke, has accepted a copy of Mr. J. S. Nettlefold's book on "Practical Housing," published by the Garden City Press at Letchworth. The book explains the methods of site planning co-partnership tenants societies and a second edition of it is being prepared.

NEW WATER-SUPPLIES.—The new water-supply for Totnes (Devon) was formally inaugurated on May 28th in the presence of a large gathering. The new supply has been granted to the town by Mr. S. Cary for 99 years, at a nominal rent, and the local authorities are entitled to take from May to November 20,000 gallons daily, which will gravitate to the highest point in the town and can be stored in any of the reservoirs.—A Local Government Board inquiry was held at Stoke St. Gregory, near Taunton, on May 20th, into the application of the Taunton rural district council for permission to borrow £8000 for the purpose of securing a water-supply for Stoke St. Gregory, Hatch Beauchamp, and North Curry.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—At a meeting of the council of this society held in London on June 3rd Mr. J. Rymer Young of Warrington was re-elected president, it being the unanimous wish of the members of the council that Mr. Young should retain his position in view of the society's attitude regarding the proposals of the Government to amend the law relating to the sale of poisons now before Parliament. Mr. J. F. Harrington was re-elected vice-president, and Mr. Walter Hills treasurer. The bronze medals for the elementary course in botany, practical chemistry, and materia medica have been awarded to Miss Grace M. Neve.—The distribution of prizes at the School of Pharmacy will take place on Wednesday afternoon, June 24th, at 3 o'clock, at 17, Bloomsbury-square, London, W.C.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Whitsuntide Holidays.

THE House of Commons has taken a very short Whitsuntide holiday this year. The adjournment took place on Thursday, June 4th, and the House reassembled on Wednesday, June 10th. Only three Parliamentary days were included in the holiday. As the House had a long holiday at Easter in consequence of the rearrangement of Ministerial offices and as much of the Government business is by no means well advanced it was felt by the PRIME MINISTER and his colleagues that only a short space of time could be devoted to the Whitsun recess this year by the Commons. The House of Lords, however, has taken a fortnight's holiday. It is understood that the Government is aiming at concluding the summer session of Parliament about July 20th and at calling Parliament together for an autumn session in October.

The Progress of Legislation.

It is the fate of most Bills introduced by private Members to remain on the notice paper awaiting second reading until the end of the session and then automatically to be extinguished. The House of Commons has not the time to examine and to deal with all the 250 Bills introduced in the course of a session and very few are permitted to pass through their various stages without discussion. There is one Bill of interest to the medical profession—the Prohibition of Medical Practice by Companies Bill—which has had the misfortune to remain unconsidered up to the present, although it was introduced in the early part of the session. It has the approval of the General Medical Council. It is in the charge of Sir JOHN TUKE whose position as Member for the Universities of Edinburgh and St. Andrews gives him considerable weight in matters affecting the learned professions. It is supported by members on both sides of the House. It was fully considered by a committee of the House of Lords last year and it passed through all its stages in that chamber. Yet when an attempt has been made to get a second reading for it at the time of unopposed business objection has been invariably taken to it. Its progress has thus been effectually blocked. Amongst other Bills which are still awaiting second reading are: the Coroners' Inquests (Railway Fatalities) Bill, the Coroners (Ireland) Bill, Lord ROBERT CECIL'S Infant Life Protection Bill, Mr. HAY'S Nurses Registration Bill, Mr. MUNRO FERGUSON'S Nurses Registration Bill, the Parochial Medical Officers (Scotland) Bill, the Public Health Officers Bill, and the Purity of Milk Supplies (Scotland) Bill. Mr. HIGHAM'S Coroners' Inquests Bill has passed through a standing committee. Bills introduced by members of the Government have special facilities for advancement. The Children Bill, which deals amongst other matters with infant life protection and juvenile smoking, has made good progress in standing committee under the care of Mr. HERBERT SAMUEL, the Under Secretary for the Home Department. Mr. BURNS'S Housing, Town Planning, &c., Bill has also been sent to a standing committee.

Tuberculosis Prevention (Ireland) Bill.

Mr. BIRRELL has at length introduced his Tuberculosis Prevention (Ireland) Bill into the House of Commons. It is designed "to prevent the spread and provide for the treatment of tuberculosis and for other purposes connected therewith." Mr. BIRRELL has the special support of Mr. CHERRY, the Attorney-General for Ireland, in bringing forward the Bill, which has, as a matter of form, been read a first time.

Experiments on Living Animals.

On the motion of Mr. HERBERT SAMUEL a return has been ordered by the House of Commons to show the number of experiments on living animals carried out under licences in the year 1907.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 3RD.

Medical Referees.

Sir CHARLES DILKE asked the Secretary of State for the Home Department whether his attention had been called to the apparent inconsistency of surgeons appointed by the Home Office to official positions as, for example, those of medical referee or certifying surgeon, holding at the same time positions in which they had to represent an interest sometimes at variance with their official functions; whether in consequence the same surgeon often had to act judicially and also to be called as a witness by a litigant in the same case; whether the certifying surgeons in the Potteries districts held appointments from the Potteries Insurance Company; whether such certifying surgeons investigated on behalf of the insurance company cases of suspected lead poisoning first diagnosed by the medical attendant of the workmen and attended the directors' meeting to be consulted by the insurance company upon cases in their respective districts; whether a workman could only receive compensation for disablement from a scheduled disease if he first obtained a certificate, while in the event of appeal against refusal of a certificate the certifying surgeon was often retained by the insurance company or employers to represent them in appeal; whether he would consider the possibility of providing in future appointments for a greater separation of duties; and in the case of lead poisoning whether he would allow the matter to be considered by the departmental committee.—Mr. GLADSTONE furnished the following written reply: In the case of medical referees under the Workmen's Compensation Act it is, with few exceptions, made a condition of appointment that the referee shall not hold any position

Notes, Short Comments, and Answers to Correspondents.

TATTOOING.

AN interesting article on tattooing in the U S. Navy appears in the April issue of the *United States Naval Medical Bulletin* by Surgeon Ammen Farenholt, U.S. Navy, attached to U.S.S. *Independence* at the Mare Island Navy Yard, California. He says: "I have recently examined the enlistment records of 3572 men, being the enlistments on this vessel for a period of eight and a half years, and have obtained the following data for that portion of our enlisted force percentage of men found tattooed on examination for second and subsequent enlistments, 53·61; percentage of men found to be tattooed on examination for first enlistment, 23·61. While the former figures give a fair estimate of tattooing among the 'old timers' it is a trifle under the correct estimate for the service as a whole, and I think it would be nearer the truth to say that about 60 per cent. of persons who have served over ten years are thus marked. On the other hand, it is not fair to assume that 23 per cent. of all male civilians are tattooed because that was found to be the percentage among those who presented themselves for first enlistment, as a considerable proportion of applicants are seafaring men, and as it is probable that some men conceal previous service." The designs were found to have been placed in the following locations according to numerical preponderance: (1) forearms, (2) arms, (3) chest, (4) shoulders, (5) hands, (6) wrists, (7) legs, (8) feet, (9) back, and (10) face. The conventional designs in order of frequency were the following (1) letters, (2) coats-of-arms, (3) flags, (4) anchors, (5) eagles and birds, (6) stars, (7) female figures, (8) ships, (9) clasped hands, (10) daggers, (11) crosses, (12) bracelets, and (13) hearts. Further particulars of Surgeon Farenholt's paper may be seen in the *Naval and Military Record* of May 21st, which has made a long quotation from the article. Those who are interested in tattooing will find some further information easily accessible in an annotation which appeared in THE LANCET of March 9th, 1872, p. 341, which gave a summary of various methods of tattooing, and in the "Twentieth Century Practice of Medicine," Vol. XII., p. 382, which contains an interesting article by Professor Cesare Lombroso. Surgeon Farenholt states that the custom probably originated among the natives of the South Sea Islands, but Professor Lombroso refers to Herodotus having observed the custom in his time. The orthodox origin is that some Scythian ladies caused some Thracian female captives to be so marked for purposes of derision, but that it afterwards became a fashion.

A few particulars of tattooing in the South Sea Islands will be found in the "Narrative of Missionary Enterprises in the South Sea Islands," by John Williams, the "Missionary of Polynesia," who was so tragically murdered in 1839. He there says: "Some were tattooed from head to foot. Some were painted most fantastically with pipe-clay and yellow and red ochre. Others were smeared with charcoal. The King Makea (of Rarotonga) was most beautifully tattooed and slightly coloured with a preparation of turmeric and ginger which gave it a light orange tinge." Speaking of another island he says: "Few of the women were tattooed, but many of them were spotted. This is what they call *sengisengi*, and is effected by raising small blisters with a wick of native cloth, which burns, but does not blaze. When they are healed they leave the spot a shade lighter than the original skin. Thus indelible devices are imprinted. They adopt this method at Samoa, and tattooing at other islands to perpetuate the memory of some important event or beloved and departed relative."

Biblical students think that the following reference in Leviticus xix. 28 has reference to what is now known as tattooing: "Ye shall not make any cuttings in your flesh for the dead, nor print any marks upon you: I am the Lord." But there is no doubt that it has been very frequent among the Polynesians and the Maori chiefs of New Zealand and the Japanese, Burmese, and Siamese. With the New Zealanders the more the marks the greater the rank was the rule. The traffic in the tattooed heads of New Zealand chiefs caused such a scandal in 1830 that it was stopped by the British Governor, Darling. Tattooing was the cause of some losing their heads it was said. The chief reason of tattooing seems to have been to insure some sign of identity in battle.

Tattooing has also been employed for motives of religion, love and vendetta, distinction, and pure love of ornament. Criminals seem to have employed it for mixed motives of recognition or fancy. It has also been employed to restore natural colours in parts which are pigmented. Those who desire to have tattoo marks removed may find profit by referring to a paragraph which appeared in THE LANCET of Nov. 30th, 1907, p. 1555. Soldiers and sailors have always been partial to tattooing and we understand that the Bethnal Green police are now trying to establish the identity of a man, apparently an old soldier, who said that he had served in Burma, who died in the Vicar of Wakefield public-house, Bethnal Green, while he was smoking a cigarette. At Bethnal Green mortuary the man's body was found to be tattooed most elaborately all over, the designs including dancing girls, swords, crossed hands, and snakes. He was about 35 years old and a letter bearing the name of Albert Francis Candell was found in the clothing. Those of our soldiers and sailors who favour tattooing may not find it an unmixed distinction. There is danger in interfering with the natural functions of the skin and also the danger of conveying specific disease and the operation should not be lightly or carelessly undertaken, and in many cases it would be better not to undergo it at all.

"BLOWN" MEAT.

AT Brighton on June 2nd Benjamin Firth Kettle, cattle-dealer, Hassocks, and Louis Neary, butcher, Hurst, were each fined £2 10*s.* and costs, the former for depositing in Brighton for the purpose of sale, and intended for the food of man, a quantity of unsound meat, and the latter for being in possession of the meat. The meat consisted of two fore-quarters, a hind-quarter, and the head and pluck of an old ewe, and the evidence of Dr. Duncan Forbes, medical officer of health, showed that the lung was extensively affected by parasitic disease, the carcass was emaciated, and the meat wet and flabby. It was stated by the sanitary inspector that air had been blown into the cellular tissues to make the carcass appear plump and to hide the emaciation, and that such a practice was common in the south in the case of lamb and veal, but not in the case of mutton. The prosecution contended that it was Kettle's custom not to deal with butchers but to visit public-houses and restaurants and to offer meat for sale. This was denied. However, a quarter of this particular ewe was discovered at a public-house and seized. The fine of £2 10*s.* seems to be hardly sufficient to act as a deterrent to what no doubt has been a very lucrative trade in unsound meat.

"AS OTHERS SEE US."

To the Editor of THE LANCET.

SIR,—The following story overheard in a railway train recently is instructive as well as amusing. My fellow-passengers were four middle-class respectable women, and were all apparently strangers to each other and to me. One was suffering from a severe cough and the conversation turned to medicine and doctors, when one of the others declared she had had "asthma" for years and had gone to several doctors who "could do nothing" for her, and now she triumphantly asserted a chemist had given her a "chest protector" which she exhibited (!) and it had cured her.

The second woman chimed in and related how she had "saved her child's life" after the doctor had given her up by giving "Turkey rhubarb, manna, and rose leaves," a prescription she had seen in a newspaper. The doctor could not understand how the child recovered and she did not tell him, as once before he had laughed when she informed him she had given saffron tea to the children when they had measles, and "every mother knew it was the best thing"! The third story, however, was the most marvellous and was told in dramatic style. Her daughter, aged 12, had been attended by a doctor for several weeks for St. Vitus's dance, but with no improvement, and he advised a visit to the seaside. They went to Southport and the next day a woman overtook them and remarked: "I see your little girl has St. Vitus's dance; if you want to cure her send 5*s.* to Mr. X. at Lancaster and he will help you." She did, and received four powders with directions to give one a week at exactly the same hour and day. The first did no good; soon after the second the child could "keep her face straight"; after the third she "stopped jerking her arms," and ten minutes after the fourth powder "power came back to her legs and she passed a long worm"! There had been no relapse and it had happened some months ago. Cases have been recorded in THE LANCET (Pereira: THE LANCET, Sept. 19th, 1903, p. 824; Hodge: THE LANCET, Oct. 31st, 1903, p. 1232) of worms causing chorea and this was undoubtedly a case. The moral is obvious.

I am, Sir, yours faithfully,

Wakefield.

A. F. THEOBALDS.

AN INCREASED SENTENCE ON A "SPECIALIST DOCTOR."

BERTRAM MORTIMORE, described as "an American specialist doctor," has furnished the first example of the increase of a sentence by the newly constituted Court of Criminal Appeal. Mortimore was sentenced to 15 months' hard labour for an offence not connected with his practice as a "specialist doctor," that of stealing a Gladstone bag from Victoria Station, but this sentence was afterwards reduced to the same period of incarceration in the second division. He appealed, and after hearing counsel on his behalf the Court of Criminal Appeal declined to grant him leave to call certain further evidence which he said he wished to lay before them, and also refused to say that the jury had been misdirected by the judge when his case was first tried. In addition to this, after mention had been made of Mortimore's antecedents, with which one of the judges composing the court happened to be acquainted, the sentence was restored to one of hard labour. The power to increase sentences upon appeal has been believed by lawyers to exist in those cases in which prisoners appeal to quarter sessions, but was never exercised so far as we are aware.

INDECENT ADVERTISEMENTS.

THE Joint Committee which is considering the question of lotteries and indecent advertisements and the adequacy or inadequacy of the present law in dealing with these matters held a sitting on June 1st, at which Mr. W. Vesey Harrel, M.V.O., Assistant Commissioner of the Dublin Metropolitan Police, gave some interesting evidence. He pointed out that in Ireland the police had the same problem before them as the English authorities have and gave it as his opinion that extended powers should be given to them for the searching of shops for the discovery of indecent wares. In one part of his evidence he uttered opinions which we have repeatedly expressed ourselves with

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Caird, Francis Mitchell, M.B., C.M. Edin., F.R.C.S. Edin., has been appointed Regius Professor of Clinical Surgery in the University of Edinburgh.

Dennis, A., L.D.S., L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon at the Royal Dental Hospital of London.

Fletcher, E. E., L.D.S., has been appointed to the Appliance Department of the Royal Dental Hospital of London.

Gemmell, Samson, M.D., C.M. Glasg., F.F.P.S. Glasg., has been appointed Professor of the Practice of Medicine in the University of Glasgow.

Harwood, L. A., L.D.S., has been appointed House Surgeon at the Royal Dental Hospital of London.

Mackenzie, Theodore Charles, M.B., F.R.C.P. Edin., has been appointed Medical Superintendent of the Inverness District Asylum.

Murphy, Edward Ernest Albert, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Assistant Medical Officer at the Devon County Asylum, Exeter.

Ovey, W. C., L.D.S., has been appointed House Surgeon at the Royal Dental Hospital of London.

Skerrett, Frank B., M.B. Lond., D.P.H., has been appointed School Medical Inspector for the County Borough of West Ham.

Smyth, F. R., L.D.S., has been appointed House Surgeon at the Royal Dental Hospital of London.

Von Bergen, C. W., M.B., B.S. Durh., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Leatherhead District of the county of Surrey.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Argentina, British Hospital, Buenos Aires.—Assistant Resident Medical Officer, unmarried. Salary £200, increasing to £300 per annum, with board and lodging.

Aylesbury, Bucks County Lunatic Asylum, Stone.—Senior Assistant Medical Officer. Salary £175 per annum, with board and apartments.

Aylesbury, Royal Buckinghamshire Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

Bangor, Carnarvonshire and Anglesey Infirmary.—House Surgeon. Salary £100 per annum, with board, washing, and lodging.

Bath, Royal Mineral Water Hospital.—Resident Medical Officer. Salary £100 per annum, with lodging, board, and laundry.

Birmingham General Dispensary.—Resident Locum. Salary £4 4s. per week, with apartments.

Bridgwater Hospital.—House Surgeon, for six months. Salary at rate of £80 per annum, with board, lodging, and washing.

Brighton, Royal Alexandra Hospital for Sick Children, Dyke-road.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

Brighton, Sussex County Hospital.—Third House Surgeon, unmarried. Salary £50 per annum, with board and residence.

Brighton Throat and Ear Hospital, Church-street, Queen's-road.—*Non-resident House Surgeon for six months, renewable.* Salary at rate of £100 per annum.

Bristol Royal Hospital for Sick Children and Women.—Assistant House Surgeon for six months. Salary £50 per annum, with board, rooms, and attendance.

Bury St. Edmunds, West Sussex General Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board and lodging.

Carmarthenshire Infirmary.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, board, attendance &c.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—House Physician for six months. Salary at rate of £50 per annum, with board, residence, and washing.

Derby, County Borough of.—Medical Officer of Health. Salary £600 per annum.

Derby, Derbyshire Royal Infirmary.—Assistant House Surgeon for six months. Salary at rate of £60 per annum, with board, residence, and washing.

Dumfries and Galloway Royal Infirmary.—Assistant House Surgeon. Salary £55 per annum, with board and lodging.

Enfield and Edmonton Isolation Hospital, World's End, Winchmore Hill.—Resident Assistant Medical Officer. Salary £150 per annum, with rooms, rations, and washing.

Evelina Hospital for Sick Children, Southwark Bridge-road, London, S.E.—Eight Clinical Assistants in the Out-patient Department. Also Honorary Anæsthetist.

Farringdon General Dispensary and Lying-in Charity, 17, Bartlett's-buildings, Holborn Circus, E.C.—Resident Medical Officer. Salary £100 per annum, with rooms, attendance, fire, &c.

King Edward VII. Sanatorium, Midhurst, Sussex.—Junior Assistant Medical Officer, unmarried. Salary £100 per annum, with board, lodging, and attendance.

Kingston-upon-Hull, City and County of.—Assistant Medical Officer of Health, unmarried. Salary £200 per annum, with residence, board, and washing.

Leicester Infirmary.—Assistant House Physician. Salary at rate of £50 per annum, with board, apartments, and washing. Also Second House Surgeon. Salary at rate of £100 per annum, with board, apartments, and washing.

Lichfield, County Asylum, Burntwood.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, attendance, and washing.

Liverpool Eye and Ear Infirmary, Myrtle-street.—Two Honorary Anæsthetists.

Liverpool Infirmary for Children.—House Surgeon. Salary £100 per annum, with board and lodging.

Liverpool, Royal Southern Hospital.—Resident Pathologist and Registrar. Salary £100, with board and residence.

Liverpool University of.—Chair of Therapeutics.

London County Asylum, Claybury, Woodford, Essex.—Assistant Medical Officer, unmarried. Salary £160 per annum, with board, apartments, and washing.

London County Asylum, Horton, Epsom, Surrey.—Assistant Medical Officer, unmarried. Salary £160 per annum, with board, apartments, and washing.

Maidstone, Kent County Asylum.—Fourth Assistant Medical Officer, unmarried. Salary £175 per annum, with quarters, attendance, washing, &c.

Manchester, Chorlton-upon-Medlock Dispensary.—Resident Medical Officer. Salary £120 per annum.

Manchester Eye and Ear Hospital, 25, St. John-street, Deansgate.—*Medical Officers for the Examination of School Children.* Also Clinical Assistants.

Manchester, St. Mary's Hospitals for Women and Children.—Resident Surgical Officer. Salary £100 per annum, with board and residence.

Metropolitan Hospital, Kingsland-road, N.E.—Assistant Surgeon.

Miller General Hospital, Greenwich-road, S.E.—Physician to In-Patients. *Also Surgeon to In-Patients.* Also Junior House Surgeon for six months. Salary at rate of £80 per annum.

Mountain Ash Urban District Education Committee.—School Medical Officer. Salary £250 per annum.

New Hospital for Women.—Two House Surgeons (females).

Northampton, County Borough of.—Assistant Medical Officer of Health. Salary £200 per annum, rising to £250.

Oldham, County Borough of.—Assistant Schools Medical Officer. Salary £200 per annum, rising to £260.

Poplar and Stepney Sick Asylum, Bromley, E.—Second Assistant Medical Officer. Salary £100 per annum, with rations, apartments, and washing.

Prince of Wales's General Hospital, Tottenham, N.—Junior House Physician. Salary £40 per annum, with residence, board, and laundry.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Two House Surgeons for six months. Salaries at rate of £60 per annum, with board, residence, and laundry.

Rangoon Municipality.—Health Officer. Salary Rs.1000, rising to Rs.1500 per mensem.

Royal General Dispensary, 25 and 26, Bartholomew's-close, E.C.—*Physician. Salary £40 per annum.*

Royal Waterloo Hospital for Children and Women, S.E.—Junior Resident Medical Officer. Salary at rate of £40 per annum, with board and washing.

St. George's Union Infirmary, Fulham-road, London, S.W.—Second Assistant Medical Officer. Salary £120 per annum, with board, residence, and washing.

Shrewsbury, Salop Infirmary.—House Physician. Salary at rate of £60 per annum, with board and apartments.

South Africa, Provincial Hospital, Port Elizabeth.—Assistant House Surgeon, unmarried. Salary £225, rising to £300 per annum, with board and residence.

Stoke-on-Trent, North Staffordshire Infirmary and Eye Hospital, Hartshill.—Junior House Surgeon. Salary £50 per annum, with board, apartments, and washing.

Syria, Lebanon Hospital for the Insane, Asfuriyeh.—Medical Superintendent. *Salary £300 per annum* and house.

West London Hospital and Post-Graduate College, Hammersmith-road, W.—Clinical Assistants *also Casualty Officers.*

Western Australia, Hospital for the Insane.—Senior Assistant Medical Officer, unmarried. Salary £380, rising to £405 per annum, with board, lodging, washing, fuel, and light. Also Junior Assistant Medical Officer. Salary £285, rising to £315 per annum, with board, lodging, washing, fuel, and light.

Western General Dispensary, Marylebone-road, N.W.—Junior House Surgeon. *Salary at rate of £80 per annum,* with board, residence, and washing.

Weston-super-Mare Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

Wolverhampton and Midland Counties Eye Infirmary.—House Surgeon. Salary £30 per annum, with apartments, board, and laundry.

Births, Marriages, and Deaths.

BIRTHS.

De Zilwa.—On May 8th, at 10, Rosmead-place, Cinnamon Gardens, Colombo, Ceylon, the wife of Lucian A. E. de Zilwa, M.D., B.Sc. Lond., *of a daughter.*

French.—On the 7th June, at 23, Porchester-gardens, Hyde Park, W., the wife of J. Gay French, M.B., M.S. Lond., F.R.C.S. Eng., of a son.

MARRIAGES.

Bramwell—Cunningham.—On June 3rd, at St. Cuthbert's Parish Church, Edinburgh, Edwin Bramwell, M.B., F.R.C.P. Edin. and Lond., to Elizabeth Cumming, elder daughter of D. J. Cunningham, F.R.S., Dean of the Faculty of Medicine in the University of Edinburgh.

DEATHS.

Bullmore.—On Thursday, June 4th, at Arwenack, Falmouth, W. King Bullmore, M.D., aged 74.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Wednesday.—Clinics:—2.30 p.m., Medical Out-patient (Dr. Whipham); Skin (Dr. Meachen); Eye (Mr. Brooks).

Thursday.—2.30 p.m., Special Demonstration of Gynæcological Operations (Dr. Giles). Clinics:—Medical Out-patient (Dr. Whiting); Surgical (Mr. Carson); X Rays. 3 p.m., Medical In-patient (Dr. Chappel). 4.30 p.m., Demonstration of Selected Medical Cases (Dr. Whiting).

Friday.—10 a.m., Clinic:—Surgical Out-patient (Mr. J. H. Evans). 2.30 p.m., Surgical Operations (Mr. Edmunds). Clinics:—Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 p.m., Medical In-patient (Dr. R. M. Leslie).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

Monday.—2.15 p.m., Sir Dyce Duckworth: Medicine. 2.30 p.m., Operations. 3.15 p.m., Mr. W. Turner: Surgery. 4 p.m., Mr. L. A. Lawrence: Ear and Throat. Out-patient Demonstrations:—10 a.m., Surgical and Medical. 12 noon, Ear and Throat.

Tuesday.—2.15 p.m., Dr. R. T. Hewlett: Medicine. 2.30 p.m., Operations. 3.15 p.m., Mr. Carless: Surgery. 4 p.m., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 a.m., Surgical and Medical. 12 noon, Skin.

Wednesday.—2.15 p.m., Dr. F. Taylor: Medicine. 2.30 p.m., Operations. 3.30 p.m., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 a.m., Surgical and Medical, 11 a.m., Eye.

Thursday.—2.15 p.m., Dr. G. Rankin: Medicine. 2.30 p.m., Operations. 3.15 p.m., Sir W. Bennett: Surgery. 4 p.m., Mr. M. Davidson: Radiography. Out-patient Demonstrations:—10 a.m., Surgical and Medical 12 noon, Ear and Throat.

Friday.—2.15 p.m., Dr. R. Bradford: Medicine. 2.30 p.m., Operations. 3.15 p.m., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 a.m., Surgical and Medical. 12 noon, Skin. Special Lecture:—*Dr. R. Bradford: Peripheral Neuritis.*

Saturday.—2.30 p.m., Operations. Out-patient Demonstrations:—10 a.m., Surgical and Medical. 11 a.m., Eye.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

Tuesday.—3.30 p.m., Lecture:—Dr. Collier: Amyotonia Congenita.

Friday.—3.30 p.m., Lecture:—Dr. Collier: Caisson Disease.

ROYAL INSTITUTE OF PUBLIC HEALTH, Theatre of the Institute, 37, Russell-square, W.C.

Wednesday.—5 p.m., Harben Lecture:—Prof. G. H. F. Nuttall: Spriochætosis in Man and Animals.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION, 11, Chandos-street, Cavendish-square, W.

Wednesday.—3.30 p.m., Discussion on the Recent Memorandum passed by the Board of Education to Local Education Authorities *re* the Medical Inspection of Elementary Schools (opened by Mr. J. Hayward).

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (15th).—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), St. George's (2 p.m.), St. Mary's (2.30 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), Chelsea (2 p.m.), Samaritan (Gynæcological, by Physicians, 2 p.m.), Soho-square (2 p.m.), City Orthopædic (4 p.m.), Gt. Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Royal Free (2 p.m.), Guy's (1.30 p.m.), Children, Gt. Ormond-street (9 a.m.), St. Mark's (2.30 p.m.), West London (2.30 p.m.).

TUESDAY (16th).—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), West London (2.30 p.m.), University College (2 p.m.), St. George's (1 p.m.), St. Mary's (1 p.m.), St. Mark's (2.30 p.m.), Cancer (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden-square (9.30 a.m.), Soho-square (2 p.m.), Chelsea (2 p.m.), Central London Throat and Ear (2 p.m.), Children, Gt. Ormond-street (9 a.m. and 2 p.m., Ophthalmic, 2 p.m.), Tottenham (2.30 p.m.).

WEDNESDAY (17th).—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (2 p.m.), National Orthopædic (10 a.m.), St. Peter's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Gt. Northern Central (2.30 p.m.), Westminster (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Cancer (2 p.m.), Throat, Golden-square (9.30 a.m.), Guy's (1.30 p.m.), Royal Ear (2 p.m.), Royal Orthopædic (3 p.m.), Children, Gt. Ormond-street (9 a.m. and 9.30 a.m., Dental, 2 p.m.), Tottenham (Ophthalmic, 2.30 p.m.), West London (2.30 p.m.).

THURSDAY (18th).—St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), University College (2 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), London (2 p.m.), King's College (2 p.m.), Middlesex (1.30 p.m.), St. Mary's (2.30 p.m.), Soho-square (2 p.m.), North-West London (2 p.m.), Gt. Northern Central (Gynæcological, 2.30 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden square (9.30 a.m.), Guy's (1.30 p.m.), Royal Orthopædic (9 a.m.), Royal Ear (2 p.m.), Children, Gt. Ormond-street (9 a.m. and 2 p.m.), Tottenham (Gynæcological, 2.30 p.m.), West London (2.30 p.m.).

FRIDAY (19th).—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), King's College (2 p.m.), St. Mary's (2 p.m.), Ophthalmic (10 a.m.), Cancer (2 p.m.), Chelsea (2 p.m.), Gt. Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden-square (9.30 a.m.), City Orthopædic (2.30 p.m.), Soho-square (2 p.m.), Central London Throat and Ear (2 p.m.), Children, Gt. Ormond-street (9 a.m., Aural, 2 p.m.), Tottenham (2.30 p.m.), St. Peter's (2 p.m.).

SATURDAY (20th).—Royal Free (9 a.m.), London (2 p.m.), Middlesex (1.30 p.m.), St. Thomas's (2 p.m.), University College (9.15 a.m.), Charing Cross (2 p.m.), St. George's (1 p.m.), St. Mary's (10 a.m.), Throat, Golden-square (9.30 a.m.), Guy's (1.30 p.m.), Children, Gt. Ormond-street (9 a.m. and 9.30 a.m.), West London (2.30 p.m.).

At the Royal Eye Hospital (2 p.m.), the Royal London Ophthalmic (10 a.m.), the Royal Westminster Ophthalmic (1.30 p.m.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of The Lancet should be addressed *exclusively* "To the Editor," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of The Lancet *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of The Lancet at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach The Lancet Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to The Lancet Offices.

Subscribers, by sending their subscriptions direct to The Lancet Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The Colonial and Foreign Edition (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from The Lancet Offices or from Agents, are:—

For the United Kingdom.		To the Colonies and Abroad.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. Charles Good, The Lancet Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given above. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of The Lancet necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of The Lancet have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

During the week marked copies of the following newspapers have been received:—*Liverpool Courier, Northern Whig, New Zealand Herald, Glasgow Times, Glasgow Evening Times, Birmingham Despatch, Morning Post, Times of India, Aberdeen Free Press, Wimborne Herald, Newcastle Daily Chronicle, Yorkshire Daily Post, Hampshire Advertiser, Aberdeen Gazette, Weekly Scotsman, Ipswich Star, North Star, Newcastle Weekly Journal, The Schoolmaster, &c.*

regard to the necessity for a wider definition of the words "indecent or obscene" and increased penalties for those guilty of obscene publication. Mr. Harrel thought that the printers and publishers of "literature" referring to medicines and appliances for the treatment of sexual disorders ought to be made liable to prosecution. This is a point which has been abundantly clear to us for a long time. The vendors of abortifacients (which may or may not cause abortion), of sexual invigorators which certainly do not invigorate, and of rubber goods are very generally the same persons. They carry on, and make money out of, an indecent trade. Claims made on behalf of their wares are false and they should be placed in the more immediate surveillance of the police.

HOSPITAL PEWTER.

LOVERS of the antique who gave an hour to the inspection of the pewter exhibited in the hall of Clifford's Inn last week have doubtless been comparing notes on the collections in their own hospitals—they happen to belong to one of the older institutions. St. Bartholomew's is justly proud of its possessions in this ancient metal, but perhaps it is not so well known that the little infirmary of the Foundling Hospital also rejoices in some very fine specimens. Among them are a handsome bowl and ewer, several "bleeding basins" with finely worked handles—reminiscent of the days of cupping and other forms of blood-letting—and a mug-shaped article with two openings at the top, to which have been assigned the alternative uses of a lamp or an inhaler. The question of how far back inhaling may have been practised is one for medical archæologists. One of the bleeding basins, which has a rather more elaborate handle than the others, is measured to hold 16 ounces. There is no clue forthcoming at present as to the date of the articles. They were found some time ago, covered with the dust of ages, in a cupboard in the old disused infirmary, and handed over to the care of the superintendent of the new one. The whole set is now kept as a prominent ornament in one of the wards, and may be seen by any visitors sufficiently interested in this great institution to penetrate as far as the infirmary.

◆

Ethics.—1. It is not customary for a medical officer of health to inspect a patient who is suffering from infectious disease and whose condition has been notified by the practitioner in attendance in the usual way. The exceptions to this rule are the very rare cases where the health officer has strong reason to doubt the good faith of the certificate or where the certificate is not explicit—e.g., as in a notification of "continued fever"—or where the disease reported is exceptional and of grave danger to the community, such as cholera or typhus fever. 2. The medical officer of health has no legal right of entry to a sickroom, save when he can show a "nuisance" to exist therein and on that ground obtains a magistrate's order to enter. He has no right to inspect patients without their consent or that of their friends, and it is highly desirable that the coöperation of the medical practitioner in attendance should be obtained before a visit for such a purpose is made, and that the inspection of the patient should have the nature of a consultation between the practitioner and the health officer, the usual courtesies of a medical consultation being strictly observed. It would be unethical for a health officer to inspect a patient without at any rate acquainting the practitioner in attendance of his intention to do so. Our correspondent will find the whole matter discussed fully in a pamphlet published by THE LANCET containing reprints of a series of special articles entitled "Difficulties under the Infectious Disease (Notification) Act."

Westminster.—We presume that our correspondent wants to know what is the custom pursued in the best professional circles, for, of course, from an ethical point of view he can adopt any style of visiting card that he likes. In this country it is quite unusual for a medical man to be described on his visiting card more fully than he would be announced on entering a room. Our correspondent being engaged in ophthalmology should describe himself simply as Mr. ——; he should not put his honour degrees or his specialty as an ophthalmic surgeon on his card. In other countries, notably in America, the reverse obtains, and certainly makes for convenience.

J. W. R.—Will our correspondent kindly send us one of the certificate forms in question?

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—Stephen Paget, H. F. Waterhouse): at 5.30 P.M.

Mr. Walter G. Spencer: Reduction of an Old Sub-coracoid Dislocation of the Humerus by Excavating the Glenoid Cavity through a Posterior Intermuscular Incision.

Mr. Alban Doran: Cystic Tumour of the Suprarenal Body successfully Removed by Operation

Mr. Rushton Parker: (1) Cases of Non-union treated by Implantation of Bone Fragments; (2) Case of very severe Compound Fracture of Arm.

(Illustrated by photographs and lantern slides).

THURSDAY.

NEUROLOGICAL SECTION (Hon Secretaries—Leonard G. Guthrie, E. Farquhar Buzzard): at 4.30 P.M.

Clinical Meeting (at the Hospital for Epilepsy and Paralysis, 4, Maida-vale).

DERMATOLOGICAL SECTION (Hon. Secretaries—A. Whitfield, E. G. Graham Little): at 5 P.M.

Clinical Cases:

Dr. Graham Little: (1) Private Case for Diagnosis; (2) Private Case of Urticaria Pigmentosa in an Adult (with sections); (3) Two Cases of Pseudo-pelade (Brocq); (4) Sections of Skin from the Case for Diagnosis and the "Varus Nodulosus" shown at the last meeting.

(And other Cases not yet notified).

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

SOCIETY FOR THE STUDY OF INEBRIETY, 11, Chandos-street, Cavendish-square, W.

TUESDAY.—3.30 P.M., Council Meeting. 4 P.M., Discussion on *Alcoholism and Cruelty to Children* (opened by Mr. R. J. Parr).

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 20, Hanover-square, W.

FRIDAY.—8.30 P.M., Annual General Meeting. Dr. C. F. Harford: Tick Fever of Africa, with Special Reference to its Clinical Manifestations and its Relation to the Relapsing Fever of India and other parts of the World.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, *Pall Mall East.*

THURSDAY.—5 P.M., Croonian Lecture:—Dr. A. E. Garrod: *Inborn* Errors of Metabolism.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. H. Sequeira: Clinique (Skin). 5.15 P.M., Lecture:—Prof. T. Hewlett: The Diagnosis of Syphilis, &c., by the Antigen Method.

TUESDAY.—4 P.M., Dr. E. Cautley: Clinique (Medical). 5.15 P.M., Lecture:—Mr. H. Evans: *Injuries to the Head* of the New Born (with lantern slides).

WEDNESDAY.—4 P.M., Mr. R. Johnson: Clinique (Surgical) 5.15 P.M., Lecture:—Mr. C. R. B. Keetley: Affections of the Toes, Feet, and Ankles.

THURSDAY.—4 P.M., Mr. Hutchinson: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. W. Langdon Brown: Diseases associated with Cyanosis.

FRIDAY.—4 P.M., Mr. A. Lawson: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—12 noon, Lecture:—Dr. Low: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M., Lecture:—Mr. Bidwell: Plaster of Paris Splints.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. 2.15 P.M., Dr. Davis: Diseases of Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. Armour: Lymphatic Gland Enlargements

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Scott: Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M., Lecture:—Mr. Armour: Thyroid Enlargements.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery.

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X *Rays.* 2.15 P.M., Dr. Davis: Diseases of Throat, Nose, and *Ear.* 2.30 P.M., *Operations.* Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. R. H. Cole: Medico-legal Relations of Insanity.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Scott: Diseases of the Eyes. 2.30 P.M., Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. J. H. Evans). 2.30 P.M., Medical Out-patient (Dr. Whipham); Nose, Throat, and Ear (Mr. Carson); X Rays. 4.30 P.M., Medical In-patient Clinic (Dr. Whiting).

TUESDAY.—Clinic:—10 A.M., Medical Out-patient (Dr. Auld). 2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Surgical (Mr. Edmunds); Gynæcological (Dr. Giles). 4.30 P.M., Demonstration of Cases at the Northwood Sanatorium (Dr. Squire).

Remarks
ON
SOME POINTS IN THE HISTORY OF ANTISEPTIC SURGERY.

BY LORD LISTER, F.R.S.

THE following unfinished letter to Sir Hector Cameron was written early in 1906, before the delivery of his lectures on the Evolution of Wound Treatment, but never sent to him. I have been assured that it would have sufficient interest for some readers to warrant its publication.

MY DEAR CAMERON,—It seems superfluous for me to write anything to you with reference to your coming lectures. But perhaps in what I shall say there may be here and there points which may interest you.

In treating surgical cases antiseptically I always endeavoured to avoid the direct action of the antiseptic substance upon the tissues, so far as was consistent in the existing state of knowledge with attaining the essential object of preventing the development of injurious microbes in the part concerned.

In compound fracture, to which in 1865 I first put in practice the antiseptic principle, I applied undiluted carbolic acid freely to the injured part, in order to destroy the septic microbes already present in it; regarding the caustic action which I knew must occur as a matter of small moment compared with the tremendous evil which it was sought to avoid. But when this had once been done no further direct action of the antiseptic upon the tissues occurred. The carbolic acid formed with the blood a dense chemical compound which, together with some layers of lint steeped in the acid, produced a crust that adhered firmly to the wound and the adjacent part of the skin. This crust was left in place till all danger was over, its surface being painted from time to time with the acid, to guard against the penetration of septic change into its substance. Meanwhile in the undisturbed wound the beautiful result occurred that the material of the crust within it, and the portions of tissue which had been destroyed by the caustic, were replaced by living tissue formed at their expense.

That dead tissue, when protected from external influences, was so disposed of was a most important truth new to pathology; and it afterwards suggested the idea of the catgut ligature.

I do not remember whether you saw the case that led me to apply the antiseptic principle to abscess. The patient was a woman above the middle period of life with lumbar abscess. Taught by the disastrous results that sooner or later followed the evacuation of such abscesses, whether by valvular opening or by cannula and trocar, I left the case undisturbed, till one day, on looking at it, I found that nothing but epidermis seemed to intervene between the pus and the external world, so that if left for another day it would in all probability burst.

I therefore resolved to open it and apply a dressing which should imitate, as much as circumstances permitted, that which we used in compound fractures. The pus which escaped on incision was as thick as any I ever saw. Mixing some of it with undiluted carbolic acid, I applied some layers of lint soaked with the mixture to the wound and surrounding skin and covered them with a piece of thin block tin moulded to proper shape, such as we used for covering the crust in compound fracture. This metal covering, which prevented loss of carbolic acid by evaporation and soaking into surrounding dressings, was fixed by strapping and a folded towel was bandaged over it to absorb discharge.

Next day, on changing the dressing, I was greatly astonished to see nothing escape from the incision except a drop or two of clear serum. What was now to be done? I had no longer any pus to mix with the carbolic acid. But it occurred to me that I might make a satisfactory crust by mixing carbolic acid with glazier's putty. Accordingly I sent to the dispensary for some whiting and boiled linseed oil, and making a solution of one part of carbolic acid in four of the oil, rubbed it up with whiting in a mortar, thus making a carbolic putty. This I spread on a piece of block tin and applied it as I had done the first dressing. There never was any further discharge of pus; the serous oozing diminished rapidly and before long healing was complete.

In that case, as there was no spinal curvature, could not be sure that the abscess was connected with the vertebræ. But similar results afterwards followed the same treatment where discharge of bone showed that such connexion existed and also in suppuration of the hip-joint, whether attended with shortening of the limb or not, scrupulous care being taken to keep the affected part completely at rest. The time required for final closing of the sinus was, however, generally much longer than in the first case.

Precisely the same beautiful result, so entirely novel and so full of deep interest both for pathology and practice, was seen when acute abscesses were treated in the same way, the only difference being that in the acute cases the serous oozing which followed evacuation of the pus came much more rapidly to a conclusion.

In order to insure freedom of escape for the serum, a narrow strip of lint soaked with a solution of carbolic acid in four parts of olive oil was inserted in the incision. But the antiseptic substance was never from first to last applied to the cavity of the abscess, as such treatment could only have been productive of needless irritation.

I continued to use a strip of lint as a drain for about five years with perfectly satisfactory results. But in 1871, having opened a very deeply seated acute abscess in the axilla, I found to my surprise on changing the dressing next day that the withdrawal of the lint was followed by escape of thick pus like the original contents.

It occurred to me that in that deep and narrow incision, the lint, instead of serving as a drain, might have acted like a plug, and so reproduced the conditions present before evacuation. Taking a piece of the indiarubber tubing of a Richardson's spray producer that I had used for local anæsthesia at the operation, I cut holes in it and attached knotted silk threads to one end, so improvising a drainage-tube. This I put to steep for the night in a strong watery solution of carbolic acid and introduced it in place of the lint on changing the dressing next morning. The withdrawal of the lint had been followed by discharge of thick pus as before; but next morning I was rejoiced to find nothing escape unless it were a drop or so of clear serum. This rapidly diminished, and within a week of the opening of the abscess I was able to take leave of my patient, the discharge from the abscess cavity having entirely ceased.

After that case I used drainage-tubes as a rule in the treatment of abscess. But it is well to remember that if such a tube should not be at hand, a narrow strip of lint, sterilised, of course, with some trustworthy antiseptic solution, will in almost every case answer the purpose equally well.

The crude carbolic acid which, under the name of German creasote, was supplied to me by my colleague Dr. Anderson, Professor of Chemistry in the University of Glasgow, was a brown liquid which had been adulterated with water, and this lay on the top as a clear layer destitute of any flavour of carbolic acid. This led me in my first paper on compound fracture to speak of carbolic acid as absolutely insoluble in water. But when it was afterwards produced in a comparatively pure condition in colourless crystals it proved to be capable of being taken up by water, though 20 parts were required for the purpose. The watery solution, however, though weak numerically, showed itself to be exceedingly potent as an antiseptic. Having applied it to a foul sore in the palm of the hand, I found, on changing the dressing next day, that all putrefactive odour had disappeared.

This enabled me to use carbolic acid for washing wounds after operations and so to extend the application of the antiseptic principle to surgery in general. In the state of knowledge at that early period it seemed imperative to apply a powerful germicide to the wound before closing it. To use undiluted carbolic acid for operation wounds, as I had done in compound fracture, was out of the question; and carbolic oil, though I did indeed try it, was ill adapted for the purpose. But the watery solution could be satisfactorily used not only for washing the wound but also for purifying the surrounding skin, the hands of the operator, and the instruments.

The entire absence of carbolic acid in the layer of water on the "German creasote" with which I made my first attempts with compound fractures indicates that there were present in the crude product substances for which the acid had incomparably greater attraction than it had for water. When purified from these substances it is indeed soluble in water, but only in small amount; and being so feebly held by water it is free, when in watery solution, to act upon

Communications, Letters, &c., have been received from—

A.—Ardath Tobacco Co., Lond; Mr. D. E. Anklesaria, Ahmedabad; Messrs. P. W. Ardran and Co., Liverpool; A. G. E.; Messrs. Claudius Ash, Sons, and Co., Lond.; Mr. J. D. E. Anklesaria, Lond.; Messrs. Allen and Hanburys, Lond.;

B.—Mr. F. A. Brockhaus, Lond.; Mr. G. P. Butcher, Plymouth; Messrs. D. Brown and Son, Lond.; Messrs. Burroughs, Wellcome, and Co., Lond.; Board of Education, Lond., Secretary of; Mr. J. S. Beveridge, Milnathort; "Brute"; Bailbrook House, Bath, Medical Superintendent of; Messrs. J. Beal and Son, Brighton; The Bayer Co., Lond.; Mr. St. John Buchan, Bangalore; Messrs. R. C. Batt and Co., Southampton; Dr. W. Cecil Bosanquet, Lond.; Mr. E. Titus Barham, Lond.; Messrs. Blundell and Rigby, Lond.

C.—Mr. V. Zachary Cope, Lond.; Co-partnership Tenants, Ltd., Lond.; Colonial Nursing Association, Lond., Secretary of; Messrs. Carnrick and Co., Lond.; Messrs. A. H. Cox and Co., Brighton; Messrs. G. W. Carnrick and Co., New York; Messrs. Carter, Lond.; C. W.; Dr. H. W. Cattel, Philadelphia; Continental Tyre and Rubber Co. (Great Britain), Lond.; City of York Education Committee, Secretary of; Messrs. Crossley and Co., Lond.; Messrs. Callard and Co., Lond.

D.—Darlington Education Committee, Secretary of; Davis (F. A.), Company, Philadelphia; Dr. E. H. Douty, Paris.

E.—Dr. E. Emrys-Roberts, Liverpool; Mr. M. D. Eder, Lond.

F.—The Fine Art Society, Lond.; Farringdon General Dispensary, Lond., Hon. Secretary of; F. W.; Messrs. J. S. Fry and Sons, Bristol; Friedenheim Hospital, Lond., Secretary of.

G.—Mr. N. E. Glanville, Lond.; Dr. E. A. Gates, Florence; Dr. J. G. Gordon-Munn, Norwich; G. H.; Dr. M. Greenwood, Lond.; Dr. Alfred Greenwood, Blackburn; Garden City Press, Lond., Representative of.

H.—Mr. N. Bishop Harman, Lond.; Messrs. Hill and Co., Lond.; Mr. Maurice C. Hime, Londonderry; Mr. C. A. Hill, Lond.; Dr. E. Harries, Lond.; Humanitarian League, Lond.; Hull Corporation, Clerk to the; Messrs. W. C. Henderson and Son, St. Andrews; Lieutenant N. H. Hume, I.M.S., Secunderabad; Dr. C. O. Hawthorne, Lond.; Huddersfield, Medical Officer of Health of.

I.—Dr. C. E. Iredell, Croydon; Ignotus.

J.—Mr. Lindsay Johnson, Lond.; Mr. John Jones, Lond.; Dr. J. Hervey Jones, Dinas Mawddwy; Mr. G. B. James, Lond.; J. W.

K.—Dr. E. Klein, Chislehurst; Dr. H. Cameron Kidd, Bromsgrove; King Edward VII.'s Hospital and Dispensary for Windsor, Eton, and District, Secretary of; Mr. E. M. Knott, Sutton Coldfield; Mr. E. Knight, Westcliff-on-Sea; K. L. S.; Dr. H. Kerr, Newcastle-on-Tyne; Messrs. Kutnow and Co., Lond.; Messrs. R. A. Knight and Co., Lond.

L.—Mr. H. K. Lewis, Lond.; Mr. C. Lillingston, Meanallen; Mr. W. Lumsden, Waterloo, Blyth; London School of Clinical Medicine, Dean of; Messrs. Lee and Nightingale, Liverpool; Mr. H. H. Lacy, Warwick; Leicester Infirmary, Secretary of; Liverpool Eye and Ear Infirmary, Secretary of.

M.—*Dr. E. D. Macnamara, Lond.*; Dr. H. McCormac, Lond.; Mr. Albert E. Morison, Sunderland; Miol Manufacturing Co., Lond.; *Midland Counties Herald*, Birmingham, Manager of; M. J. H.; Messrs. Maple and Co., Lond.; Manchester *Royal Infirmary*, Secretary of; Dr. C. J. Morton, Lond.

N.—Mr. Cyril A. R. Nitch, Lond.; North Staffordshire Infirmary, Hartshill, Stoke-on-Trent, Secretary of; N. G., Lond.; Mr. H. Needes, Lond.; Mr. J. C. Needes, Lond.

O.—Odol Chemical Works, Lond.; Mr. Joseph Offord, Lond.

P.—Dr. W. T. Prout, Liverpool; Mr. J. Prior Purvis, Lond.; Dr. F. J. Poynton, Lond.; Mr. *W. H. Persse, Lond.*; *Pharma*ceutical Society of Great Britain, Lond.; Messrs. C. Pool and Co., Lond.; Prince of Wales General Hospital, Lond., Secretary of; Messrs. W. Porteous and Co., Glasgow; Pearson's Antiseptic Co., Lond.; Messrs. Peacock and Hadley, Lond; Dr. T. W. S. Paterson, Lond.; Fleet-Surgeon A. M. Page, R.N., Plymouth.

R.—Dr. J. W. Rob, Weybridge; Royal Microscopical Society, Lond.; Royal Southern Hospital, Liverpool, Superintendent of; Dr. A. B. Rafle, South Shields; Messrs. Reynell and Son, Lond.; Royal Mineral Water Hospital, Bath, Registrar of; Royal Mail Steam *Packet Co., Lond.*; Dr. F. W. Forbes Ross, Lond.; Research Defence Society, Lond., Hon. Secretary of.

S.—Dr. W. C. Sullivan, Lond.; Messrs. G. Street and Co., Lond.; Dr. F. W. Stewart, Maidstone; Society for the Destruction of Vermin, Lond., Secretary of; Smith's Advertising Agency, Lond.; Messrs. Southall Bros. and Barclay, Birmingham; Dr. D. Lloyd Smith, Kingswood; Stepney Spare Motor Wheel, Llanelly, Manager of; Scholastic, Clerical, *&c.*, Association, Lond.; Star Engineering Co., Wolverhampton; Messrs. Simpkin, Marshall, Hamilton, Kent, and Co., Lond.; Dr. T. B. Smith, Bellshill; Sanitary Inspectors' Examination Board, Lond., Hon. Secretary of.

T.—Dr. A. F. Theobalds, Wakefield; Mr. John M. Thompson, Chicago; T. F. D.

U.—Mr. J. J. Udale, Lond., *United States Patent Office*; Washington, Commissioner of; Mr. Harold Upcott, Hull.

V.—Dr. I. F. B. de Villiers, Oudtshoorn.

W.—Mr. Lewis Waterman, Bristol; Messrs. W. *Wood and Co.*, New York; Dr. W. Wallace, Lond.; Surgeon Colonel F. H. Welch, Lond.; Mr. F. A. Watkins, Lond.; Dr. W. J. Wilson, Belfast; West Suffolk General Hospital, Bury St. Edmunds, Secretary of; "Westminster"; Dr. W. H. Willcox, Lond.

Y.—Mr. P. *Macleod* Yearsley, Lond.

Letters, each with enclosure, are also acknowledged from—

A.—Ashwood House, Kingswinford, Superintendent of; A. F.; Anglo-American Pharmaceutical Co., Croydon, Secretary of; Messrs. Abel Heywood and Son, Manchester; *A. H. M. C.*; *Fleet*-Surgeon T. Austen, R.N., Chatham; Apollinaris Co., Lond.

B.—Dr. W. E. Barton, Lond.; Mr. L. A. Bidmore, Falmouth; Burntwood Asylum, Lichfield, Medical Superintendent of; Messrs. W. H. Bailey and Son, Lond.; Burnley Guardians, Clerk to the; *Beckett Hospital*, Barnsley, Matron of; Bank of Madras, Madras, Manager of; Messrs. J. B. Boyd and Co., Manchester.

C.—Dr. R. A. Chisolm, Lond.; C. E. R. B; Cheltenham Education Committee, Secretary of; Dr. T. Carruthers, Kilbarchan; Mr. A. Connell, Sheffield; Messrs. Cowley and Co., Manchester; *Chester Courant*, Chester, Manager of; Carmarthenshire Infirmary, Carmarthen, Secretary of; C. *J.* M. F.

D.—Dr. J. H. Drysdale, Lond.; Dr. A. E. De Zilwa, Colombo; Dr. W. T. Dougal, Pittenweem; Major C. Donovan, I.M.S., Nungumbakam.

E.—Mr. G. S. Earl, Southampton; Electromobile Co., Lond., Managing Director of; East Suffolk and Ipswich Hospital, Secretary of; Evening News Co., Portsmouth, Manager of; E. H.

F.—Mr. F. T. Fagge, Llanfairfechan; F. E. W.

G.—Mr. E. Gooch, Lond.; G. D. C.

Quarter Page, £1 10s. Half a Page, £2 15s. An Entire Page, £5 5s.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to insure *insertion the* same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold *himself* responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements: copies only should be forwarded.

Cheques and Post *Office Orders* (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom *all letters relating* to Advertisements *or* Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapst, Asnières, Paris.

again, we find that some diseases are more virulent in children than in adults, and *vice versâ*. Perhaps the most striking fact of all, and the one to which I wish especially to draw your attention, is that in diseases which are common to both children and adults the organs and tissues which are attacked by the virus may differ markedly according to the age of the patient

That such differences in the incidence of disease in children and adults are very common is a point which hardly requires any elaboration. The *exanthemata*, for instance, are very often spoken of as children's ailments, and some explain the fact that they are most frequent in children by saying that practically all individuals are highly susceptible to them, and being widely spread, no individual can live long in the world without being exposed to infection. This may be in part true, but I can hardly accept it as a complete explanation of the facts; I cannot but think that, quite irrespective of opportunities of infection, the susceptibility of the individual varies according to age. Even in the case of children, the exanthemata differ among themselves as to the age when they most frequently occur: for example, measles is not uncommon during the first year of life, and something like 90 per cent. of the cases occur in children under five years of age, while scarlet fever rarely occurs in infants, although patients suffering from it may be present in the house or even in the same room, and the favourite age for scarlet fever is from three to ten years. Then, again, chicken-pox occurs at a somewhat later period than scarlet fever; it is not so universally distributed, and it very rarely affects adults.

To take an organism whose life-history is known, we have a very good example of varying susceptibility at different ages in the case of the *pneumococcus*. This organism attacks the body more readily in childhood than in adult life, or as I would prefer to put it, the resisting power of the human body to the pneumococcus is apparently *lower in children* than in adults; thus it *seems to* be the fact that pneumococcal pneumonia is *more common* in children under five years of age than during any other quinquennial period. One of the most interesting points from a surgical point of view is the relation of the pneumococcus to *pleurisy and empyema*. The organisms which are most commonly at work in setting up these conditions are the pneumococcus, the streptococcus pyogenes, and the tubercle bacillus; *other organisms*, such as bacillus coli, staphylococcus, &c., are quite rare. Now the relative frequency *of these organisms* in cases of empyema differs very markedly in children and adults. Thus in children over 60 per cent. of the cases of empyema are due to the pneumococcus, about 15 per cent. to the streptococcus, and about 7 per cent. to the tubercle bacillus. In adults, on the other hand, the *proportions are*: pneumococcus, 25 per cent.; streptococcus, 41 per cent.; and tubercle bacillus, 18 per cent. Thus the pneumococcus is the most common cause of empyema in children and the streptococcus in adults. In children pneumonia is present in cases of pleurisy in from 25 to 50 per *cent.*; in adults it is present in only about 20 per cent Further, pleurisy more often becomes purulent in children than in adults; indeed, empyema after pleurisy is about four or five times more common in the former than in the latter.

I think there can be little doubt that the meaning of these facts is that children have less resisting power against the invasion of the pneumococcus than is *the case* in adults, and this view is strengthened by the fact that we more often meet with pneumococcal invasion of other parts of the body than the lungs and pleura in children than in adults. Thus we find that while pneumococcal peritonitis occurs at all ages it is much more frequent in children, being most common between three and ten years of age. Similarly pneumococcal disease of joints is also most common in children, and the general invasion of the body by the pneumococcus is a very striking feature in early childhood and is most marked in infants, where we may have a regular pneumococcal septicæmia.

I need not give further examples of the general proposition that differences do occur in the incidence of various infective diseases in children and adults respectively, but may at once go on to the consideration of further points in connexion with such differences. The question of infection is a very complex matter, and a variety of factors come into play in connexion with it. On the one hand, we have the *invading parasites*, and on the other the *defensive arrangements* of the body against this invasion. I need not here go into the questions which relate to the parasites, their virulence, their habitat in the body, their habitat outside the body, the varying ease with which they gain access to the body, and so on, seeing that these points are the same whether the individual who is attacked is young or old. Passing, however, to the other partner in the infective process—namely, the animal body, we find that there are a variety of conditions which are necessary before the invading organisms can obtain a foothold in the body.

The *first line of defence* of the body resides in all probability in the epithelial tissues which oppose the entrance of infective agents into the body, and differences in the amount of resistance which they oppose to the entrance of organisms exist at different periods of life.

It is not as yet possible to define the exact meaning of the condition of the epithelium which enables it to oppose invasion. It clearly must be a local power residing in the epithelial cells themselves, or in the fixed cells on which they are situated, rather than any general condition such as the presence of opsonins in the blood, &c. It is interesting to note, as shown long ago by Lister, that where the epithelium lining a canal, the sides of which are normally in contact, is intact and healthy, bacteria cannot spread along that canal. This is true in the case of many ducts, such as the urethra, the mammary ducts, the salivary ducts, &c., and Lister used to point to this as a proof of the vital power of the tissues in preventing the growth of bacteria.

A very good example of variation in the defensive power of epithelium according to age is furnished by the behaviour of the *gonococcus*, and two points occur in connexion with this organism in children. In the first place there are reasons for believing that the susceptibility of children to the invasion of the gonococcus is greater than in adults; and in the second place the organism attacks epithelial tissues *in children, which are more or less* immune in adults. The very mode in which infection occurs in the two cases seems to imply a diminished resisting power on the part of children, for in them infection is usually accidental, being conveyed by dirty sponges, soiled linen, &c. No doubt the anatomical development of the parts such as the vulva, as age advances, may render accidental infection less easy in adults than in children, but still it occurs more readily in the latter than this would account for. The incubation period in children is also apparently shorter than in adults. The disease as it occurs in young people after infection is usually more severe than in adults, and there are various observations which seem to show that discharges which are no longer capable of infecting the mucous membranes in adults are virulent for those of children. The greater readiness with which the conjunctiva becomes infected in children may also point to increased susceptibility to the gonococcus, though possibly the fact that in infants the conjunctiva is only *one* layer of cells thick may have something to do with the greater susceptibility. The special interest, however, centres in the location of the disease in children and adults respectively—namely, in the fact that the vaginal mucous membrane is more often and more violently attacked by the gonococcus than in adults. In adults, as a matter of fact, the disease is usually *located in the cervix uteri* or in the mucous membrane of the urethra, while involvement of the vaginal mucous membrane is relatively rare and slight. Some, indeed, altogether deny the susceptibility of the vaginal mucous membrane to the gonococcus in adults and hold that when it is diseased it is only affected by a sort of desquamative catarrh caused by the maceration of the mucous membrane from the passage of the pus over it. While the vaginal mucous membrane in children is thus highly susceptible to the gonococcus it is curious that other complications caused by this organism are not so common nor so severe in children as in adults. No doubt gonococcal peritonitis does occur and it is quite likely that the so-called spontaneous peritonitis in young girls is often of gonococcal origin. Gonococcal cystitis is also not uncommon, but gonococcal infection of joints is rarer than in adults. It most commonly affects only one joint, usually the knee; hydrarthrosis is not observed, ankylosis is very rare, and on the whole the course of gonococcal joint troubles is more benign and not so chronic as in adults.

Another example of the relation of organisms to the first line of defence is furnished by the behaviour of the pyogenic organisms in the skin. *Multiple abscesses of the skin* and subcutaneous tissues are quite common in infants Impetigo is also common, but boils rarely occur. The reverse is the case in adults, where multiple abscesses of the skin are quite other matters for which it has stronger attraction. Thus was explained the remarkable germicidal energy of a lotion containing only a twentieth part of carbolic acid, as illustrated by the foul sore in the hand before referred to.

With linseed oil, on the other hand, the acid could be mixed in any proportion, and being firmly held by the oil it was mild in action, though present in the large proportion of 1 to 4, as used in the carbolic putty. The 1 to 4 carbolic oil is bland when applied to the tip of the tongue, whereas the 1 to 20 watery solution is intolerably pungent.

The acid in the watery solution, while potent in action when applied, is soon dissipated, whereas it is slow in leaving the oil. Hence the watery solution, powerful but transient in operation, was admirably adapted for application to a cut surface as a detergent, while the carbolic putty, bland in action and serving long as a store of the antiseptic, could be used with good effect not only for abscesses but also as an external dressing for operation wounds, and for that purpose I long employed it. The putty was used in a layer spread on calico, freely overlapping the skin around the wound and covered with a folded cloth to absorb the serum that flowed from beneath its edges. Although this mode of dressing gave place in time to others which were more convenient, the change effected under its use at that early period was of the most striking character: healing without suppuration, pain, or fever, instead of being the rare exception, became the rule, and operations were safely performed which had previously been utterly prohibited on account of the danger that attended them, while pyæmia and hospital gangrene, which had before been disastrously rife, were banished from my wards.

Epidermis is a substance for which carbolic acid has special attraction; and this, coupled with the facility with which the acid blends with oily matters, renders it peculiarly fitted for purifying the skin about the seat of operation and the surgeon's hands. Another property which aids its action as a detergent is its great penetrating power, not limited by the products of its chemical action upon organic substances.

I used the 1 to 20 watery solution for rendering the patient's skin and the hands of myself and my assistants aseptic throughout the 40 years during which I practised on the antiseptic principle, and I never had any reason to doubt its efficacy. No long time is required for its action. In my private practice the purification of the skin was as a rule not begun till I entered the patient's room to perform the operation. The part concerned was then thoroughly washed with the 1 to 20 carbolic solution and was kept covered with lint soaked with the same lotion while the instruments were being attended to and the anæsthetic administered, the whole process occupying only about a quarter of an hour. Yet experience showed that this brief period was sufficient.

It may perhaps be argued that under the carbolic putty or any other dressing containing carbolic acid, that volatile agent was perpetually acting on the skin and may have made up for deficiencies in the original purification. But during several years before I gave up practice the dressings did not owe their virtues to any volatile antiseptic.

I may mention in illustration one of my latest operations. The patient was a lady advanced in years, with a large ventral hernia below the umbilicus. It was producing serious symptoms; and attempts to reduce it having failed, her condition had become exceedingly grave. I only began to disinfect the skin when she was already partly under the influence of the anæsthetic. The umbilicus contained some drops of opaque liquid of a highly offensive character. I cleansed its folds carefully with the 1 to 20 carbolic solution and washed the skin over and around the sac with the same lotion. The sac was opened by a median incision, the upper end of which extended to the umbilicus. Into further details of the operation I need not enter. On changing the dressing (of cyanide gauze) it appeared that, in her frail condition, the margins of the skin at the upper end of the incision had lost their vitality over an extent of about half an inch in length and one-tenth of an inch in breadth at each side. I afterwards left the dressing unchanged for several days, when I found that the sloughs, the upper ends of which encroached on the umbilicus, so foul before the operation, had been replaced by new living tissue, and complete cicatrisation had occurred without the formation of a particle of pus.

I cannot but think it a happy circumstance that the substance which I employed first in endeavouring to apply the antiseptic principle should have been so admirably adapted for detergent purposes. And it has grieved me to learn that many surgeons have been led to substitute needlessly protracted and complicated measures for means so simple and efficient.[1]

As an instance of trouble misapplied in this matter, may be mentioned preliminary washing with soap and water. If carbolic acid is the disinfectant used, such washing is not only wholly unnecessary, but is, I believe, positively injurious; as it must tend to check the penetration of the germicide into the substance of the epidermis, by saturating it with water for which carbolic acid has so little affinity. That this practice is superfluous is, I venture to think, proved by my experience, as I never in any case adopted it.

The incomparably greater attraction of carbolic acid for epidermis than for water was strikingly illustrated by an experiment not hitherto published. . . . . .

Here my letter was broken off, in consequence of other engagements. But I afterwards wrote to Sir Hector Cameron what I had intended to say on this subject and he was good enough to incorporate my remarks in his second lecture.[2]

The Wightman Lecture

ON

THE DEFENSIVE ARRANGEMENTS OF THE BODY AS ILLUSTRATED BY THE INCIDENCE OF DISEASE IN CHILDREN AND ADULTS.

Delivered before the Society for the Study of Disease in Children on May 22nd, 1908,

By W. WATSON CHEYNE, C.B., F.R.S., &c.,
SENIOR SURGEON TO KING'S COLLEGE HOSPITAL, ETC.

GENTLEMEN,—The choice of a subject for the present lecture has been a matter of very great difficulty, and if it has not been a very fortunate one I must crave your kind indulgence. It seems to me that the object of lectures such as these is best attained by making an attempt to present a wide view of some general subject and one suggestive of future research rather than to discuss some more limited matter which would be better suited for a paper at an ordinary meeting of the society. Hence it was among the former class of topics that my choice lay, and it has occurred to me that the subject of the relative resisting power of children and adults against infective diseases was well worth special study.

In dealing with diseases of children and adults one is often struck by the fact that marked variations occur at different ages; indeed, it is the existence of these variations which justifies a partial separation of children's diseases from those of adults, and the establishment of separate children's hospitals or, at any rate, of wards in general hospitals set apart for the treatment of children. In the present lecture I shall speak only of diseases which are due to the entrance of parasitic organisms from without with special reference to the points of difference in children and adults. I am not able to explain these differences satisfactorily, I can only indicate some of the points which arise in the hope that some members of this society who have more time and more ability than I have will turn their attention to the study of these matters. I believe that the successful study of the differences in the resisting power of children to infective diseases as compared with adults will give the key to much of the obscurity and difficulty which still surround the questions of infection, protection, and immunity.

In looking into this subject we find that there are some diseases which practically only occur during childhood, and *vice versâ* that there are certain diseases common in adult life which hardly ever affect children. Again, we find that there are many infective diseases which attack both adults and children, but the young are more especially susceptible to some, while their elders are more susceptible to others. Or, the epiphysis itself, and boys and girls are affected pretty equally. The anatomical arrangement of the part may possibly exercise some influence in favouring infection and determining the spread of the disease but it is evidently a very minor factor.

---

[1] The fear sometimes expressed of poisonous effects from carbolic acid, as used in antiseptic surgery, is, so far as my experience goes, entirely groundless

[2] Brit. Med. Jour., April 6th, 1907, p. 799.

It seems to me, then, that the localisation of the disease is in the main a vital question which may be summed up under the term "*local predisposition.*" As showing the complexity of this subject it may be pointed out that similar tissues in different parts of the body do not show the same susceptibility. Thus we know that the gonococcus seldom affects any mucous membranes except those of the urethra and the conjunctiva. And we shall presently see how tissues of various joints and bones in the body react differently to the tubercle bacillus at different ages. The same is the case if we take more general diseases. Thus in the case of plague Dr. W. J. Simpson points out that bubonic plague especially attacks the lymphatic glands in the groin and the axilla, especially in the groin, no matter whether the infection has occurred by punctures of the surface or in some less defined manner. We must therefore assume that the lymphatic glands in the groin differ in some way or other in their vital relations to these particular organisms from other lymphatic tissues in the body. To take another example, in acute tuberculosis, although we must assume that there is a general flooding of the blood stream with tubercle bacilli and that the circulating blood carries organisms all over the body, we nevertheless find that the bacilli are not deposited and grow anywhere indifferently but that they select certain organs and tissues. For example, they are seldom found in the muscles and cellular tissues. In the case of infants who die from tuberculosis during the first four months of life it is found that the disease is practically always general, but the parts of the body in which the tubercles are deposited vary very considerably. Thus in post-mortem examinations of these infants tubercles are found in the lungs in all cases, in the bronchial glands in 99 per cent. of the cases, in the liver in 88 per cent., in the spleen in 86 per cent., in the brain in 24 per cent., and so on. And again, taking the brain for example, they are not equally deposited over the whole brain but prefer to locate themselves along the vessels at the base.

This local predisposition varies to a very marked extent with the age of the patient, the parts affected differing at different periods of life. Perhaps the best example of these variations is furnished by the incidence of *tuberculous diseases of bones and joints* at various ages. In the great majority of cases of tuberculous disease where the bacilli which escape into the blood stream are few in number a very close selection is made, and only one or at most a few local deposits occur, and that apparently only under the most favourable conditions. What these conditions are which favour the deposit of tubercle bacilli in a particular part we really do not know, but, as has just been said, they vary with age and to some extent with sex, and also with a variety of so-called predisposing causes, such as injury or chronic inflammation.

Some years ago I collected a large number of cases of diseases of bones and joints in adults and children which had been treated in hospital, and the following remarks are founded on these statistics. In the first instance, taking a general view of the relative frequency of disease in bones and joints at different ages, I would direct attention to the accompanying table, which gives the percentage frequency of the total cases of disease of bones and joints in my list in each quinquennial period up to the age of 40 years.

TABLE I.—*Percentage Frequency of Cases of Disease of Bones and Joints in Each Quinquennial Period up to the Age of 40 Years.*

Age-periods—years.	Percentage of total number of cases.	Age-periods—years.	Percentage of total number of cases.
1 to 5	23·3	21 to 25	8·5
6 ,, 10	18·0	26 ,, 30	8·6
11 ,, 15	14·3	31 ,, 35	4·0
15 ,, 20	15·0	36 ,, 40	3·0

This table indicates clearly the great importance of age in relation to the occurrence of these diseases, but it does not accurately represent the facts of the case. Thus it may quite well be that a greater number of cases occur during the first five years of life, because a greater number of persons are alive at that age than during any other quinquennial period. Conversely, for the same reason, it may turn out that the disease is much more frequent than appears to be the case during the later quinquennial periods, owing to the smaller number of persons alive at that time. Investigations of this kind have been made with regard to phthisis, and have led to the surprising result that in Copenhagen, Sweden, and various German cities with regard to which calculations have been made, the danger of phthisis in any given individual constantly increases with advancing age, and that in advanced life a larger proportion of the individuals alive at that age die from phthisis than at the period of life in which it has been supposed to be most common.

Employing the German statistics of the proportion of persons per 1000 alive at various ages, I have calculated the real frequency of the disease in my cases, and in the following table we have the ratio per 1000 of my cases of disease of the seven larger joints, beginning in each quinquennial period. In the second column I give the apparent frequency of the cases without relation to the number of persons alive at the different ages, and in the third column the real frequency as calculated by the above method. I only give the results up to 45 years of age:—

TABLE II.—*Ratio per 1000 of Cases of Disease of the Seven Larger Joints in Each Quinquennial Period up to the Age of 45 Years.*

Age-period—years.	Apparent frequency.	Real frequency.
1 to 5	232	157
6 ,, 10	153	134
11 ,, 15	150	145
16 ,, 20	153	164
21 ,, 25	85	98
26 ,, 30	88	120
31 ,, 35	41	60
36 ,, 40	30	48
41 ,, 45	20	42

From this table it will be seen broadly that the real frequency of these diseases is actually greater in advanced life than would appear from the ordinary statistics, but still a good deal less than in youth. In my list the disease commences most frequently between one and five years of age; it then declines and rises again between 15 and 20 years; it subsequently steadily declines, with the exception of slight rises between 35 and 40 years and 45 and 50 years. The accuracy of the last numbers, which are not given here, is, however, very doubtful, because the cases in my list which commenced at those ages were quite few in number. Great differences also exist as to the period of life at which the disease commences in the different joints and bones, as is evident from the following table, in which I have indicated the percentage proportion of the cases of disease in each of the seven larger joints, commencing in each decade:—

TABLE III.—*Percentage Proportion of Cases of Disease of each of the Seven Larger Joints in each of Five Decades.*

Joints.	Decades.				
	I.	II.	III.	IV.	V.
Hip	30·2	29·3	4·8	—	12·5
Knee	29·5	22·5	18·2	36·6	6·2
Ankle	5·4	5·9	3·6	3·3	12·5
Tarsus	4·6	5·9	8·4	3·3	18·7
Shoulder... ...	—	1·6	4·8	—	—
Elbow	6·7	9·2	6·0	13·3	18·7
Wrist	0·6	8·4	15·8	13·3	6·2

Thus reading the table from above downwards we see that of the total cases of tuberculous bone and joint disease which commenced during the first decade, 30·2 per cent. were cases of hip-joint disease, 29·5 per cent. were cases of knee-joint disease, and so on. Reading the table from side to side, we see the frequency with which disease of each part commences in each decade; thus hip joint disease commences most often during the first decade, and its frequency diminishes very rapidly. The knee-joint is also very frequently attacked during the first decade, but the fall in its frequency is by no means so rapid, and so on.

Not only does the resisting power of the body vary in the same individual at different ages, but it is very interesting to note that it often varies very considerably in the two uncommon, their place being taken by boils. What the explanation of the difference is is not quite clear, but it is quite possible that in this instance it is in the main a question of differences in the anatomical structure of the skin rather than of general defensive arrangements. Thus in children the desquamation of the skin is more active and there is also incomplete development of the corneous layer of the epidermis in various places; in fact, the epidermis in children is very thin and extremely fragile and it desquamates readily, leaving the rete mucosum exposed. The papillary layer of the skin is also very rich in blood-vessels and reacts readily to all irritations.

Having overcome the first line of defence, the parasites either produce a local disease at that part, as we have seen in the case of the gonococcus, or else (and this happens in the majority of cases) they pass on into the lymph or blood stream and are carried to various parts of the body. In this latter case, having passed the epithelial line of defence, they then find themselves in closed tubes lined with endothelium. Apparently some forms of bacteria, having reached the circulating blood, can multiply in it and set up disease, but the great majority, and probably to a greater or less extent all, have to find a local resting place; if they fail to do so they quickly die out. We may imagine the bacteria being carried along in the circulation through the various tissues of the body, investigating these tissues as they pass through them till at last they find somewhere or other in the endothelial lining of the vessels conditions which are favourable for their growth or penetration, and therefore we may assume the existence of a *second defensive arrangement—namely, the endothelium.* Having found a weak spot in the endothelial lining they grow there and produce disease or else they pass through the wall of the vessel as they did through the epithelium, and multiply in the tissues outside. We have evidence that in a good many cases the parasites grow in the endothelial lining of the vessels. In syphilis, for example, endarteritis is the chief lesion and is probably due to localisation of the spirochæta in the inner coat of the small vessels. In the case of tubercle also I pointed out some years ago in my essay for the Astley Cooper prize that many tubercles are formed in the first instance in the interior of the blood-vessels possibly by proliferation of the endothelium, and in some specimens one can see tubercles in all stages clearly illustrating this point.

What the local predisposition on the part of the endothelium and the tissues signifies it is difficult to say. To some slight extent it may have to do with the *general trophic condition of the parts*, as influenced by the action of the nerves. In connexion with this point I may refer to the interesting observations which have been made by Mr. Cheatle on the sites of development of epithelial cancer and its mode of spread, in which he produces some very remarkable examples of the spread of cancer along certain definite nerve areas, avoiding neighbouring areas supplied by other nerves. To a considerable extent it may be a question of *pabulum.* That the nature of the pabulum is of very great importance in the artificial cultivation of micro-organisms is, of course, well known. We know, for example, that it is not easy to cultivate the tubercle bacillus outside the body; we know that in cultivating the gonococcus it is necessary to have a little human blood on the surface of the cultivating medium to enable the growth to start; and we know that up to the present investigators have not been able to find a soil and external conditions which are suitable for the growth of various other infective organisms, such as those of leprosy, &c. It is, therefore, not at all unlikely that in the living body the question of suitable pabulum may have a good deal to do with the localisation and growth of the organisms.

An example which seems to point in this direction is that of *ringworm of the scalp.* This disease may affect children of all ages but is rarely noticed before three or after 14 years of age; it never appears after the age of 15 and adults may mix freely with children suffering with ringworm of the scalp without being attacked by the disease, while on the other hand it is extremely infectious for children and will run through a school very quickly. The disease if left to itself disappears spontaneously at puberty, fresh and healthy hairs growing on the affected site. This is a very curious case and it seems difficult to frame a reasonable explanation. The fungus penetrates into the hairs close to the roots, but it evidently does not destroy the hair bulbs, otherwise the hairs would not grow again. It is therefore growing in what is practically dead tissue, or at the best in tissue of extremely low vitality, and the curious thing is that though it grows readily in this tissue in children it cannot grow in what is to all appearance the same material in persons over 15 years of age. Is it that there is a difference in the chemical composition of the hairs in adults and children, and is it only in children that they provide suitable food for the fungus? or is it that the fungus penetrates into tissue which still retains a certain amount of vitality, and are there more vitality and more resisting power in it in adults than in children? Whatever be the explanation, I think that this question of the suitability or unsuitability of the food which the parasite finds in the part which it invades must not be overlooked in considering the various factors which go to make up the defensive arrangements of the body.

Another example which may be mentioned in this connexion is that of the common *threadworm*, which is only, or at any rate very much more often found in children than in adults. Threadworms are very common in the large intestine of children, and they probably enter along with the food or drink. They occur in children at an age when their food is practically the same as adults, and yet threadworms are essentially a disease of childhood. May not this again be simply a question of pabulum? Is there a difference in the contents of the large intestine in children and adults, consisting in the presence of substances suitable for the existence of these worms in the former, such substances disappearing as the individual reaches adult life? Or is it that there is something in the intestinal secretions of adults which is inimical to the growth of the threadworm and which is absent in children? This might be an interesting physiological problem to work out. I can hardly think that in this case, at any rate, it can be a question of tissue resistance, for the worms grow in the fæces and can hardly be affected by the living cells lining the canal.

In this connexion, also, I may refer to an interesting point—viz., that bacteria of the same species may acquire a special appetite, so to speak, for certain tissues. For example, while we look on the staphylococcus pyogenes as an organism which may cause suppuration indifferently in any suitable tissue in which it may happen to find a proper resting place, we find that in certain cases where fresh developments of these organisms take place in the same individual, they are apt to occur in connexion with similar tissues. Thus I have repeatedly seen cases of staphylococcal osteomyelitis in which fresh outbreaks of osteomyelitis have occurred in several bones in succession without the occurrence of suppuration in other tissues of the body, as if the organisms which had settled in the bone in the first instance had acquired an appetite for bone, and when carried to other parts of the body again selected the growing ends of the bone for their development. This is perhaps still better seen in tubercle, where in cases of tuberculous disease of the bone we not uncommonly find that if fresh tuberculous disease occurs it is in other bones, and the tubercle may remain limited to bone for a long time. This is often the case, for example, in infants with tuberculous osteomyelitis of the small bones of the hands and feet. Again, we have the tubercle bacilli in some cases showing a special tendency to grow in the lymphatic glands and not for a time spreading in other tissues, or in other cases growing in the skin and giving rise to lupus without leading to tuberculous disease elsewhere.

Stress has also been laid by some on the *anatomical arrangements* of the various parts as favouring the deposit of micro-organisms in certain situations. For example, in the case of osteomyelitis the slower circulation at the epiphysial line may permit the deposit of organisms at that part, and thus account for the localisation in cases of this disease; indeed, it has been found experimentally that pigment granules injected into the blood are deposited in these situations. We cannot, however, accept this as the only, or indeed as a particularly important, factor, for many things point to something much more far-reaching than a mechanical deposition of bacteria. Thus the incidence of disease in various bones differs according to age and also according to sex. For example, osteomyelitis is most common between the ages of 12 and 18, and at that age it is more frequent in the lower extremity than in the upper and also more frequent in boys than in girls. On the other hand, the disease may attack children at a much earlier period of life, even below two years of age; in that case the upper extremity is affected nearly as often as the lower; the limitation of the disease in the first instance to the epiphysial line is not so marked, and indeed the lesions may occur in the epiphysis itself, and boys and girls are affected pretty equally. The anatomical arrangement of the part may possibly exercise some influence in favouring infection and determining the spread of the disease but it is evidently a very minor factor.

It seems to me, then, that the localisation of the disease is in the main a vital question which may be summed up under the term "local predisposition." As showing the complexity of this subject it may be pointed out that similar tissues in different parts of the body do not show the same susceptibility. Thus we know that the gonococcus seldom affects any mucous membranes except those of the urethra and the conjunctiva. And we shall presently see how tissues of various joints and bones in the body react differently to the tubercle bacillus at different ages. The same is the case if we take more general diseases. Thus in the case of plague Dr. W. J. Simpson points out that bubonic plague especially attacks the lymphatic glands in the groin and the axilla, especially in the groin, no matter whether the infection has occurred by punctures of the surface or in some less defined manner. We must therefore assume that the lymphatic glands in the groin differ in some way or other in their vital relations to these particular organisms from other lymphatic tissues in the body. To take another example, in acute tuberculosis, although we must assume that there is a general flooding of the blood stream with tubercle bacilli and that the circulating blood carries organisms all over the body, we nevertheless find that the bacilli are not deposited and grow anywhere indifferently but that they select certain organs and tissues. For example, they are seldom found in the muscles and cellular tissues. In the case of infants who die from tuberculosis during the first four months of life it is found that the disease is practically always general, but the parts of the body in which the tubercles are deposited vary very considerably. Thus in post-mortem examinations of these infants tubercles are found in the lungs in all cases, in the bronchial glands in 93 per cent. of the cases, in the liver in 33 per cent., in the spleen in 33 per cent., in the brain in 27 per cent., and so on. And again, taking the brain for example, they are not equally deposited over the whole brain but prefer to locate themselves along the vessels at the base.

This local predisposition varies to a very marked extent with the age of the patient, the parts affected differing at different periods of life. Perhaps the best example of these variations is furnished by the incidence of *tuberculous disease of bones and joints* at various ages. In the great majority of cases of tuberculous disease where the bacilli which escape into the blood stream are few in number a very close selection is made, and only one or at most a few local deposits occur, and that apparently only under the most favourable conditions. What these conditions are which favour the deposit of tubercle bacilli in a particular part we really do not know, but, as has just been said, they vary with age and to some extent with sex, and also with a variety of so-called predisposing causes, such as injury or chronic inflammation.

Some years ago I collected a large number of cases of diseases of bones and joints in adults and children which had been treated in hospital, and the following remarks are founded on these statistics. In the first instance, taking a general view of the relative frequency of disease in bones and joints at different ages, I would direct attention to the accompanying table, which gives the percentage frequency of the total cases of disease of bones and joints in my list in each quinquennial period up to the age of 40 years.

TABLE I.—*Percentage Frequency of Cases of Disease of Bones and Joints in Each Quinquennial Period up to the Age of 40 Years.*

Age-periods—years.	Percentage of total number of cases.	Age-periods—years.	Percentage of total number of cases.
1 to 5	[illegible]	20 to 25	[illegible]
5 " 10	[illegible]	25 " 30	[illegible]
10 " 15	[illegible]	30 " 35	[illegible]
15 " 20	[illegible]	35 " 40	[illegible]

This table indicates clearly the great importance of age in relation to the occurrence of these diseases, but it does not accurately represent the facts of the case. Thus it may quite well be that a greater number of cases occur during the first five years of life, because a greater number of persons are alive at that age than during any other quinquennial period. Conversely, for the same reason, it may turn out that the disease is much more frequent than appears to be the case during the later quinquennial periods, owing to the smaller number of persons alive at that time. Investigations of this kind have been made with regard to phthisis, and have led to the surprising result that in Copenhagen, Sweden, and various German cities with regard to which calculations have been made, the danger of phthisis in any given individual constantly increases with advancing age, and that in advanced life a larger proportion of the individuals alive at that age die from phthisis than at the period of life in which it has been supposed to be most common.

Employing the German statistics of the proportion of persons per 1000 alive at various ages, I have calculated the real frequency of the disease in my cases, and in the following table we have the ratio per 1000 of my cases of disease of the seven larger joints, beginning in each quinquennial period. In the second column I give the apparent frequency of the cases without relation to the number of persons alive at the different ages, and in the third column the real frequency as calculated by the above method. I only give the results up to 45 years of age:—

TABLE II.—*Ratio per 1000 of Cases of Disease of the Seven Larger Joints in Each Quinquennial Period up to the Age of 45 Years.*

Age-period—years.	Apparent frequency.	Real frequency.
1 to 5	[illegible]	[illegible]
5 " 10	[illegible]	[illegible]
10 " 15	[illegible]	[illegible]
15 " 20	[illegible]	[illegible]
20 " 25	[illegible]	[illegible]
25 " 30	[illegible]	[illegible]
30 " 35	[illegible]	[illegible]
35 " 40	[illegible]	[illegible]
40 " 45	[illegible]	[illegible]

From this table it will be seen broadly that the real frequency of these diseases is actually greater in advanced life than would appear from the ordinary statistics, but still a good deal less than in youth. In my list the disease commences most frequently between one and five years of age; it then declines and rises again between 15 and 20 years; it subsequently steadily declines, with the exception of slight rises between 35 and 40 years and 45 and 50 years. The accuracy of the last numbers, which are not given here, is, however, very doubtful, because the cases in my list which commenced at those ages were quite few in number. Great differences also exist as to the period of life at which the disease commences in the different joints and bones, as is evident from the following table, in which I have indicated the percentage proportion of the cases of disease in each of the seven larger joints, commencing in each decade:—

TABLE III.—*Percentage Proportion of Cases of Disease of each of the Seven Larger Joints in each of Five Decades.*

Joints.	Decades.				
	I.	II.	III.	IV.	V.
Hip	30·2	[illegible]	[illegible]	—	[illegible]
Knee	29·5	[illegible]	[illegible]	[illegible]	[illegible]
Ankle	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
Tarsus	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
Shoulder ...	—	[illegible]	[illegible]	—	—
Elbow	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
Wrist	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]

Thus reading the table from above downwards we see that of the total cases of tuberculous bone and joint disease which commenced during the first decade, 30·2 per cent. were cases of hip-joint disease, 29·5 per cent. were cases of knee-joint disease, and so on. Reading the table from side to side, we see the frequency with which disease of each part commences in each decade; thus hip-joint disease commences most often during the first decade, and its frequency diminishes very rapidly. The knee-joint is also very frequently attacked during the first decade, but the fall in its frequency is by no means so rapid, and so on.

Not only does the resisting power of the body vary in the same individual at different ages, but it is very interesting to note that it often varies very considerably in the two uncommon, their place being taken by boils. What the explanation of the difference is is not quite clear, but it is quite possible that in this instance it is in the main a question of differences in the anatomical structure of the skin rather than of general defensive arrangements. Thus in children the desquamation of the skin is more active and there is also incomplete development of the corneous layer of the epidermis in various places; in fact, the epidermis in children is very thin and extremely fragile and it desquamates readily, leaving the rete mucosum exposed. The papillary layer of the skin is also very rich in blood-vessels and reacts readily to all irritations.

Having overcome the first line of defence, the parasites either produce a local disease at that part, as we have seen in the case of the gonococcus, or else (and this happens in the majority of cases) they pass on into the lymph or blood stream and are carried to various parts of the body. In this latter case, having passed the epithelial line of defence, they then find themselves in closed tubes lined with endothelium. Apparently some forms of bacteria, having reached the circulating blood, can multiply in it and set up disease, but the great majority, and probably to a greater or less extent all, have to find a local resting place; if they fail to do so they quickly die out. We may imagine the bacteria being carried along in the circulation through the various tissues of the body, investigating these tissues as they pass through them till at last they find somewhere or other in the endothelial lining of the vessels conditions which are favourable for their growth or penetration, and therefore we may assume the existence of a *second defensive arrangement—namely, the endothelium.* Having found a weak spot in the endothelial lining they grow there and produce disease or else they pass through the wall of the vessel as they did through the epithelium, and multiply in the tissues outside. We have evidence that in a good many cases the parasites grow in the endothelial lining of the vessels. In syphilis, for example, endarteritis is the chief lesion and is probably due to localisation of the spirochæta in the inner coat of the small vessels. In the case of tubercle also I pointed out some years ago in my essay for the Astley Cooper prize that many tubercles are formed in the first instance in the interior of the blood-vessels possibly by proliferation of the endothelium, and in some specimens one can see tubercles in all stages clearly illustrating this point.

What the local predisposition on the part of the endothelium and the tissues signifies it is difficult to say. To some slight extent it may have to do with the *general trophic condition of the parts*, as influenced by the action of the nerves. In connexion with this point I may refer to the interesting observations which have been made by Mr. Cheatle on the sites of development of epithelial cancer and its mode of spread, in which he produces some very remarkable examples of the spread of cancer along certain definite nerve areas, avoiding neighbouring areas supplied by other nerves. To a considerable extent it may be a question of *pabulum.* That the nature of the pabulum is of very great importance in the artificial cultivation of micro-organisms is, of course, well known. We know, for example, that it is not easy to cultivate the tubercle bacillus outside the body; we know that in cultivating the gonococcus it is necessary to have a little human blood on the surface of the cultivating medium to enable the growth to start; and we know that up to the present investigators have not been able to find a soil and external conditions which are suitable for the growth of various other infective organisms, such as those of leprosy, &c. It is, therefore, not at all unlikely that in the living body the question of suitable pabulum may have a good deal to do with the localisation and growth of the organisms.

An example which seems to point in this direction is that of *ringworm of the scalp.* This disease may affect children of all ages but is rarely noticed before three or after 14 years of age; it never appears after the age of 15 and adults may mix freely with children suffering with ringworm of the scalp without being attacked by the disease, while on the other hand it is extremely infectious for children and will run through a school very quickly. The disease if left to itself disappears spontaneously at puberty, fresh and healthy hairs growing on the affected site. This is a very curious case and it seems difficult to frame a reasonable explanation. The fungus penetrates into the hairs close to the roots, but it evidently does not destroy the hair bulbs, otherwise the hairs would not grow again. It is therefore growing in what is practically dead tissue, or at the best in tissue of extremely low vitality, and the curious thing is that though it grows readily in this tissue in children it cannot grow in what is to all appearance the same material in persons over 15 years of age. Is it that there is a difference in the chemical composition of the hairs in adults and children, and is it only in children that they provide suitable food for the fungus? or is it that the fungus penetrates into tissue which still retains a certain amount of vitality, and are there more vitality and more resisting power in it in adults than in children? Whatever be the explanation, I think that this question of the suitability or unsuitability of the food which the parasite finds in the part which it invades must not be overlooked in considering the various factors which go to make up the defensive arrangements of the body.

Another example which may be mentioned in this connexion is that of the common *threadworm*, which is only, or at any rate very much more often found in children than in adults. Threadworms are very common in the large intestine of children, and they probably enter along with the food or drink. They occur in children at an age when their food is practically the same as adults, and yet threadworms are essentially a disease of childhood. May not this again be simply a question of pabulum? Is there a difference in the contents of the large intestine in children and adults, consisting in the presence of substances suitable for the existence of these worms in the former, such substances disappearing as the individual reaches adult life? Or is it that there is something in the intestinal secretions of adults which is inimical to the growth of the threadworm and which is absent in children? This might be an interesting physiological problem to work out. I can hardly think that in this case, at any rate, it can be a question of tissue resistance, for the worms grow in the fæces and can hardly be affected by the living cells lining the canal.

In this connexion, also, I may refer to an interesting point—viz., that bacteria of the same species may acquire a special appetite, so to speak, for certain tissues. For example, while we look on the staphylococcus pyogenes as an organism which may cause suppuration indifferently in any suitable tissue in which it may happen to find a proper resting place, we find that in certain cases where fresh developments of these organisms take place in the same individual, they are apt to occur in connexion with similar tissues. Thus I have repeatedly seen cases of staphylococcal osteomyelitis in which fresh outbreaks of osteomyelitis have occurred in several bones in succession without the occurrence of suppuration in other tissues of the body, as if the organisms which had settled in the bone in the first instance had acquired an appetite for bone, and when carried to other parts of the body again selected the growing ends of the bone for their development. This is perhaps still better seen in tubercle, where in cases of tuberculous disease of the bone we not uncommonly find that if fresh tuberculous disease occurs it is in other bones, and the tubercle may remain limited to bone for a long time. This is often the case, for example, in infants with tuberculous osteomyelitis of the small bones of the hands and feet. Again, we have the tubercle bacilli in some cases showing a special tendency to grow in the lymphatic glands and not for a time spreading in other tissues, or in other cases growing in the skin and giving rise to lupus without leading to tuberculous disease elsewhere.

Stress has also been laid by some on the *anatomical arrangements* of the various parts as favouring the deposit of micro-organisms in certain situations. For example, in the case of osteomyelitis the slower circulation at the epiphysial line may permit the deposit of organisms at that part, and thus account for the localisation in cases of this disease; indeed, it has been found experimentally that pigment granules injected into the blood are deposited in these situations. We cannot, however, accept this as the only, or indeed as a particularly important, factor, for many things point to something much more far-reaching than a mechanical deposition of bacteria. Thus the incidence of disease in various bones differs according to age and also according to sex. For example, osteomyelitis is most common between the ages of 12 and 18, and at that age it is more frequent in the lower extremity than in the upper and also more frequent in boys than in girls. On the other hand, the disease may attack children at a much earlier period of life, even below two years of age; in that case the upper extremity is affected nearly as often as the lower; the limitation of the disease in the first instance to the epiphysial line is not so marked, and indeed the lesions may occur in the largest number of cases occur below 20 years of age and therefore presumably during the most susceptible period, the greatest mortality takes place in patients above 20 years of age. In the case of tubercle we find also that while it is most common in young people the disease is most obstinate and less amenable to treatment in old people. And again with regard to tubercle, while it is not common during the first year of life, when it does occur it assumes a very grave type owing chiefly to the fact that it is very apt to become generalised, and this is also true in the case of other infections, such as pneumococcal, streptococcal, &c. We have, however, many examples in the other direction. Typhus fever, for instance, is rarer in children than in adults, but it is not so dangerous in children as in adults. Again, typhoid fever is not so common in young children as in young adults, being most frequent between 20 and 30 years of age and quite exceptional below eight years of age. We may therefore assume that susceptibility to typhoid fever is small below eight years of age, that it reaches its height between 20 and 30 years of age, and again diminishes later. But the curious point is that the mortality increases as the age advances, being 11·3 per cent. in children below ten years of age and reaching 34 per cent. in persons over 50 years of age. Other examples of both these points might be given but the above will suffice for our purpose.

A probable explanation of these facts is somewhat difficult to formulate, but the two following points are, I think, worth taking into consideration. In the first place, I have already referred to the question of relative dosage of bacteria in speaking of injury, and it is quite possible that this point also comes into play here. Thus, while a comparative small dose will suffice to set up the disease in a susceptible individual it requires a larger dose where the subject is less susceptible. And in accordance with the results which I obtained some years ago the resulting disease with the larger dose in the less susceptible individual would be more severe than that with the smaller dose in the more susceptible person. But in the second place I would point out that it is as a rule when the less susceptible individual is over the average age that the resulting disease is more severe, whereas this is not necessarily the case when he is under the average age, always excepting the first year of life. Hence it is probable that another factor besides resisting power comes into play in infective disease, and it is with the view of calling attention to this other possible factor that I have introduced the matter here; this factor may be indefinitely spoken of as *recuperative power*. It is quite probable that apart from the agents which actually take their place in the fight against the invading parasites there are other agencies which have to do with the maintenance of the health of the body and with the restoration of strength after it has been subjected to infection, and those I should group under the term "recuperative power." And I am inclined to think that some factor of this kind plays an important part in the recovery of patients from infective disease, quite apart from any anti-toxic or anti-bacterial agencies. Leaving out the question of infective diseases, we know that as people get older they do not recover so quickly and perfectly from injury or illness as is the case in youth. To some extent, and probably to a considerable extent in old people, this has to do with the gradual onset of degenerative changes in the various tissues and perhaps more especially in connexion with the blood-vessels. If I am correct in suspecting the existence of some further vital energy of this kind its importance in treatment cannot be overlooked, and especially it warns us not to pin our faith as regards treatment to one single point but to try to influence all the agencies which have to do with the well-being of the individual.

Time will not permit me to pursue this subject further. I could have mentioned many other facts in illustration of the points to which I have referred, but those which I have picked out seem sufficient to show the bearings of the matter and to indicate its great interest and importance. Especially I think there can be no doubt of the existence of local conditions in the tissues and organs of the body which have a very important bearing on the occurrence of infection and on recovery from it. Indeed, in my opinion, the local conditions, which we have grouped together under the heading of "local resisting power," are of much more importance than any general agency which may be present in the blood stream.

I have already indicated some points which have to be taken into consideration in connexion with this question of local resisting power but in spite of all the work that has been done we are still in the stage of theory One point I may refer to in connexion with this matter and that is the remarkable difference as regards leucocytosis in the new-born and in later life, taking the example of erysipelas. Erysipelas shows very marked differences in gravity at various periods of life and under various circumstances, and it is more especially grave in the case of infants. Infantile erysipelas usually appears from the tenth to the fifteenth day after birth and generally spreads from the umbilicus. Its mortality at that age is at least 50 per cent., but the mortality steadily falls in older children. On examining the parts in infantile erysipelas the interesting fact is observed that there is almost complete absence of local leucocytosis. In the adult, leucocytes group themselves in large numbers around and within the blood and lymphatic vessels, while in the new-born one finds the vessels dilated it is true, but this is due to the presence of masses of streptococci and not to leucocytes. Enlargement of the lymphatic glands, which also occurs in adults, may be very slight or absent in children.

On the other hand, leaving out the first year of life, there seems to be a slight increase in general leucocytosis in children under ten years of age as compared with older people in some of these infective conditions. This has been especially pointed out in cases of otitis and mastoiditis.

That the conditions summed up under the term "local resisting power" are much more important than the more general conditions seems to me to be certain and I have mentioned quite a number of points which indicate this. I have especially referred to the varying local incidence of disease at different ages and under different conditions; and I may also mention another very striking point as showing the importance of local as compared with general defensive arrangements. It is this, that in some cases one finds a disease making good progress towards healing at one part of the body, while at the same time a fresh outbreak is taking place at another. Take, for example, the case of tertiary syphilitic ulcerations. One of the important diagnostic points after a tertiary ulcer has lasted for some time is the tendency which it has to heal at one side while it spreads at the other, in this way giving rise to the serpiginous form of these ulcers. If the healing were due to general conditions in the serum, why should it not occur all round, and why, if the resisting power has been so much improved as to lead to healing at one part, does the disease actually progress at another part in the vicinity? The same is frequently seen in the case of tuberculosis; it is not at all uncommon to find one tuberculous deposit healing or becoming quiescent, while another becomes active or a fresh one actually appears. A very good example of that is seen in tuberculosis of the epididymis, where the disease on the one side and also in the vesiculæ seminales may be steadily improving when all of a sudden the other side becomes affected and not uncommonly runs a more virulent and rapid course than the first. I have seen exactly the same thing happen on several occasions in cases of tuberculosis which had been under steady opsonin treatment for a long time, some of them over a year. Thus, in one case of tuberculous epididymitis which I recall the disease in the epididymis was particularly acute in the first instance, and I advised opsonic treatment rather than operation. Ultimately, however, as the testicle became completely destroyed by suppuration, castration became necessary. Opsonic treatment was still steadily continued under the best auspices, but in spite of that, residence at the seaside, &c., the disease appeared acutely in the other epididymis, while the treatment was still going on, and I had to perform an epididymectomy without delay in order to save the other testicle. The course which the disease followed was in reality the same as if no attempt had been made to increase the general resisting power.

At the present time it is the fashion to look on the opsonic content of the blood as the essential agent concerned in bringing about immunity and cure in the case of infective diseases. This is a matter on which neither time nor knowledge permits me to enter at length. I have, however, searched the literature, inquired among investigators, and had a few observations made for me without finding any marked differences in the opsonic index to different organisms at various periods of life corresponding to the variations in the incidence of disease, and in their course at different ages; nor has any difference in the opsonic index to various infective organisms been pointed out as regards sex, and yet, as we have seen, there are noticeable variations in the incidence and severity sexes. Thus, speaking of tuberculous diseases of bones and joints, I find that of the patients on my list 65 per cent. were males and only 35 per cent. were females. Indeed, most forms of surgical tuberculosis are more frequent in boys than in girls. The following table[1] gives the percentage relations of males and females (hospital in-patients) in regard to diseases of the seven larger joints, and it will be noticed that not only are males more frequently affected than females but that the proportion differs in different joints. And not only are there differences in the incidence of disease in the two sexes, but the disease in the female seems to be as a rule more benign than in the male. That is a very interesting matter, which, however, I have no time to discuss here. I may also remark that while this is the case with regard to diseases of joints it does not necessarily hold good with regard to some other forms of tuberculous disease. Thus tuberculous peritonitis is almost equally frequent in the two sexes, while lupus is much more common in females than in males.

TABLE IV.—*Percentage Relations of Males and Females in Each Joint*

Sexes.	Hip.	Knee.	Ankle.	Tarsus.	Shoulder.	Elbow.	Wrist.
Males	59·7	57·6	81·9	85·8	50	74·3	75 9
Females	40 3	42·4	18·1	14·2	50	25 7	24·1

The predisposition and resisting power of the body, both local and general, to parasitic invasion vary very markedly under a variety of circumstances and are often *very sensitive to external conditions.* Even the *seasons of the year* apparently have their influence on the resisting power of the body. For example, erysipelas is more frequent at certain periods of the year than at others, especially during February and November, and lupus is said to improve in autumn and to become worse in spring.

One of the most important causes which influence the local predisposition of a part is *injury.* In the case of the epithelial tissues injury is naturally of great importance in connexion with their defensive action. If there is a solution of continuity in these tissues parasites may enter through a breach of the surface without being subjected to the action of the epithelium at all. On the other hand, without actually destroying the epithelium, the injury may so depress the vitality of the cells that they can no longer successfully resist the parasitic invasion.

A very good example of the effect of injury is furnished by the history of tuberculous disease of bones and joints, and the facts are of considerable interest. As a rule, where a case of joint disease is referred to an injury the history given is usually that of some slight injury, such as a strain or slight blow; indeed, it is noteworthy that after severe injuries in tuberculous subjects, such as fractures or amputations, tuberculous disease does not occur at the seat of injury. Thus, I can recall more than one instance of patients suffering from tuberculous joint disease who sustained fractures, in one case of the shaft of a bone, the epiphysis of which was already diseased, where the fractured ends have reunited without the development of any tuberculous disease at the seat of injury. And as regards amputation, unless the operation is carried out through parts which are actually diseased, one does not expect to have a tuberculous stump as a result, however many tuberculous lesions the patient may suffer from. We also not uncommonly notice that after tuberculous joint disease has become quiescent, or even apparently got well, it may recur as the result of a slight injury.

A further point which is worth mentioning is that injury to some joints seems more likely to be followed by tuberculous disease than injury to other joints. This fact is in accordance with the view which the above tables must lead us to assume, that the different joints vary in their predisposition to tuberculous disease, and that consequently injury is more likely to have an effect in determining its occurrence in those joints which are naturally the most predisposed.

Lastly, I may mention that it seems from my statistics, with which I need not trouble you here, as if injury were not only an active agent in the production of these diseases, but also determined a graver form. In my list the cases in which injury was given as a cause were on the whole more serious than those where no cause was assigned, whether we judge by the occurrence of suppuration, the results as regards complete recovery, or the severity of the treatment required for the cure.

One very obvious way in which injury may act in determining the occurrence and localisation of infective diseases is by leading to extravasation of blood, and if bacilli happen to be floating in the blood, to their consequent deposit in the part, in this way breaking down the second line of defence—namely, the endothelium—just as the first line of defence may be broken down. Apart from actual rupture of vessels and extravasation of blood, injury may favour the deposit of bacilli in the part, in that it leads to changes similar to those noticed in the early stage of inflammation. These changes involve, I believe, in the first instance, a diminution in the resisting power of the tissues. I fancy that at the present time such a view of the result of the early stage of inflammation would hardly be assented to, because the leucocytosis which accompanies it is looked on as a most important part of the protective arrangements of the body. I would, however, refer to Lister's early observations on inflammation, especially on the effects of inflammation on the activity of the pigment cells of the frog, to show what a paralysing effect irritation has in the first instance on the functions of the tissue cells of the affected part, and my belief is that the essential resisting power of a part as regards local infection lies in the tissue cells rather than in the adventitious leucocytes which come into it subsequently, and this may explain the greater severity of the disease after injury. I have formerly pointed out that where an extra large number of infective agents enters a part a more severe form of disease always results, and it must be remembered that this question of dosage of infective agents is, of course, relative to the resisting power of the part. Where, therefore, a similar quantity of bacteria has entered two parts, one of which has been rendered less resistant as the result of injury, this dose will act in the latter case in the same way as if a large dose had been administered under ordinary circumstances.

Resisting power is also influenced by a variety of conditions apart from those already mentioned, and these are often spoken of as *predisposing causes of disease.* There seems no reason to doubt that exposure to cold especially affecting a sensitive mucous membrane is a potent factor in permitting the entrance of pathogenic organisms, and very probably has a great deal to do with the penetration of such organisms as the pneumococcus into the body, especially into the lungs. *Bad hygiene, bad food, starvation, alcoholism,* &c., are also important agents in lowering the resisting power of the body to disease, and the same is frequently seen as the result of *other illnesses*, such as influenza, measles, chicken-pox, &c. To take the case of multiple abscesses in the skin in childhood to which we have already referred, we find that they often follow acute and chronic illnesses. Thus, they are frequent during convalescence from infective diseases, such as typhoid fever, pneumonia, influenza, &c., and in the course of measles, scarlet fever, and small-pox abscesses and even gangrene of the skin frequently occur. They are also quite common in tuberculous children. Presumably, therefore, these diseases lower the resistance of the body to the staphylococcus, and yet, curiously enough, taking tuberculosis for example, I find no evidence that the opsonic index to staphylococcus is as a rule seriously lowered in cases of tuberculosis.

In connexion with this question of variation in the resisting power at different ages a very interesting point arises which is worth mentioning here. One would naturally assume that if one individual is more susceptible than another to a disease he would also be affected by that disease in a more severe form, and no doubt this is true in a very considerable number of cases, but there are a number of very remarkable exceptions. In the case of the exanthemata, although I cannot speak with authority, I have seen it stated, and I have been brought up in the belief that if an adult is attacked the disease is more likely to assume a severe type than in the case of a child. And yet we have already assumed that an adult is less susceptible than a child. In the case of pneumococcal invasion of the lungs, although rendered it quite unnecessary to examine the interior of the viscus. Some among the four cases of duodenal ulcer or stenosis I should certainly have missed altogether had not the finger been passed through the pylorus. In one instance nothing abnormal was observed externally, but on introducing the finger an ulcer on the inner surface of the duodenum extending deeply into the pancreas was discovered. In another case an opening was seen with the speculum in the neighbourhood of the pylorus and it looked like the pyloric aperture, but on inserting the finger was found to be a funnel-like ulcer, extending through a rounded adhesion into the liver substance.

---

[1] I would not, however, press the actual percentages which are mentioned in this table, because in some of them, especially in the case of the shoulder, the number of patients was too small to be of value.

STENOSIS OF THE PYLORUS AND DUODENUM.

The symptoms of this condition are so well known that I need not recapitulate them, but will only observe that in some cases of pyloric stenosis in which atony has supervened the vomiting may become frequent, so that the characteristic clinical feature of infrequent copious vomiting is lost. On the other hand, an ulcer in the pyloric antrum, although only involving part of the circumference, may cause symptoms of pyloric stenosis presumably from spasm. My statistics include nine cases operated on for stenosis: six pyloric, two duodenal, and one for perigastric adhesions. There is also one case included among the chronic ulcers which showed gastrectasis and marked pyloric narrowing associated with an open ulcer. In all of these cases posterior gastro-jejunostomy was performed and all recovered. Pyloroplasty was done on one patient with pyloric stenosis in 1900. Recurrence of symptoms began 15 months later and I performed gastro-jejunostomy four years after the first operation. After-results of gastro-jejunostomy for stenosis: only one patient was lost sight of. The seven remaining cases were seen at periods varying from nine months to 63 months, with the exception of one reported after five months. Three were known to have gained from two to two and a half stones in weight. The fat and healthy appearance of these patients was sufficient evidence that the non-passage of chyme through the duodenum does not perceptibly affect nutrition. The site of the stenosis of the duodenum in both cases was in its first part. The symptoms had existed 30 and 12 years respectively, and these were similar to those of pyloric stenosis. One patient was a medical man, aged 38 years. By external examination the pylorus was evidently patulous but the stomach much dilated. An opening was made in a suitable position in the posterior wall of the stomach and a finger passed through the pylorus came upon a diaphragm-like contraction of the duodenum, the surface of which was ulcerated.

The case of perigastric adhesions was unusual. The patient, aged 25 years, had been operated on for suppurating tuberculous glands on the right side of the abdomen and his stomach symptoms developed after that illness. He was much improved by gastro-jejunostomy, but three and a half years later was found to be suffering from mucous colitis. Dr. R. Hutchison informs me that this is not uncommon after gastro-jejunostomy.

A woman, aged 33 years, had swallowed spirits of salts (HCl) four months previously. She was very ill and thin and could not swallow solid food. An œsophageal bougie lodged at the cardiac orifice. She had pain after food and vomiting. A tender dull lump was felt in the epigastrium. The stomach was evidently dilated. I operated in October, 1905, and found a tight stricture in the pyloric antrum. A posterior gastro-jejunostomy was done and a gastrostomy by Witzel's method. She made a good recovery and when I saw her two years and four months later she was well nourished, without pain or vomiting, and the stomach was contracted. She could eat anything but had to bite up her meat carefully, otherwise it lodged in the œsophagus. The gastrostomy opening had closed. Mr. B. G. A. Moynihan has published a similar case.[2]

OPERATIONS FOR ULCER.

Of the 19 cases of ulcer operated on 16 were gastric and three duodenal. *Posterior* gastro-jejunostomy was performed in 17 cases and anterior in two cases. Of the 16 cases of gastric ulcer three of the patients died, these being the only deaths in the series. One died on the fifth day from lobar pneumonia, both lungs being in the condition of grey hepatisation. The subject of one of the earlier cases (1901) died on the fifth day from exhaustion. The pathologist found the gastro-jejunostomy wound healed and there were no peritonitis and no pneumonia. Probably at the present time when feeding by the mouth is commenced earlier this patient would have survived. The third patient, also a case early in the series, died on the fifteenth day owing to ulceration and giving way of the stitches at the right end of the stoma. She was an extremely emaciated woman, aged 22 years, and was found to have an irregular ulcer some three inches in diameter on the posterior wall of the stomach, exposing the pancreas. With regard to the after-histories, all the cases were traced except one, leaving 15. The result was good in eight, fair in one; in one case there was relapse, one patient had bilious vomiting, and one is still in the hospital. Three of the patients died later, one from phthisis; one patient suffering from chronic gastric ulcer was reported to have died from perforation in an infirmary from one to two years after the operation; and the third patient, the subject of duodenal ulcer, died after returning home, 40 days after the operation, from uncontrollable hæmorrhage, to which he succumbed in two or three days. This patient, a man, aged 35 years, was found on introducing the finger through the pylorus to have an ulcer on the inner surface of the duodenum with a ragged base which extended deeply into the pancreas. The anterior operation was performed as the stomach was bound down by posterior adhesions.

Secondary entero-anastomosis was performed twice. One patient, a male, four and a half months after the first operation had some recurrence of pain four hours after food. Bismuth passed freely through the stoma and at the second operation there was no evidence of kinking, &c. The ulcer was situated in the pylorus and first portion of the duodenum and it was thought that the duodenal ulceration had recurred. The symptoms were relieved by entero-anastomosis. A female patient developed bilious vomiting on the tenth day. A secondary operation performed some time later showed recent tuberculous peritonitis with adhesions and thickening above the efferent end of the stoma.

Thirteen of the cases occurred in males and only six in females. These numbers accord closely with the statistics of Dr. Seymour Taylor, who estimates that 72 per cent. of the cases of chronic ulcer occur in men and only 28 per cent. in women. In 89 necropsies the Fenwicks found among 30 acute ulcers, three males and 27 females; among 59 chronic, 43 males and 16 females. The general view of sex incidence is probably expressed by Dreschfeld who places it as three females to one male among clinical cases; and two females to one male among post-mortem cases.[3]

The preponderance of *males* affected bears out an axiom which I have reiterated on many occasions—namely, that a case of recurring attacks of stomach trouble or the existence of inveterate dyspepsia with hæmatemesis or melæna in a man, especially if there be a point of deep tenderness, may almost certainly be diagnosed as chronic ulcer, whereas in women the diagnosis can often only be decided by exploration. Evidence of the truth of the latter part of this assertion will be brought forward in dealing with the cases of hæmorrhagic gastritis.

In the series of ulcers, hæmatemesis or melæna or both were present in 15 out of the 19 cases.

EROSIONS AND HÆMORRHAGIC AND NEURASTHENIC GASTRITIS.

Twelve cases fall under this heading, in all of which the stomach was thoroughly explored, so that there cannot, I think, be any reasonable doubt of the nature of the disease. Ten cases occurred in females and only two in men, thus presenting a striking contrast as regards sex to the group of ulcers. Erosions were only found in three cases. The erosions I have seen during life have always been tiny bleeding points which by no stretch of the imagination could be called an ulcer. There must, however, have been a microscopic denudation of epithelium. Owing to the want of harmony between ante- and post-mortem appearances it becomes a question whether the erosions observed post mortem and described by Dieulafoy are not in great measure due to post-mortem digestion at the sites of embolic hæmorrhages and minute abrasions.

As a sample of the prevailing symptoms among cases coming under the above heading I may cite the following.

A female, aged 28 years, had suffered with indigestion for 12 years, during which she had had six attacks of pain and vomiting after food, and hæmatemesis was of these diseases in the two sexes. It must, however, be pointed out that this matter of alterations in the opsonic index in connexion with age, sex, &c., has not yet been worked out from the point of view taken in this lecture, and we must not, therefore, lay too much stress on our present knowledge on this point. It is a matter which it would be quite worth while looking into. The only investigations actually bearing on this point which I have come across are some described by Dr. J. H. Wells in the May number of the *Practitioner*. He has made observations on the opsonic index in infants under one year old, with the result that he finds marked differences in young babies as compared with older people. He comes to several conclusions, of which I may mention the following. "A low opsonic index is not diagnostic in children under one year old." "In infants a low opsonic index is not inconsistent with health and the child may be thriving well with a declining index." "The antibacterial defence in children cannot depend upon the opsonic content of the serum." These are very important conclusions, and if found to apply to a sufficiently large number of cases they raise the question whether the significance of the opsonic index and opsonins generally is being properly interpreted. Although infective troubles when they do occur in infants are as a rule more acute than in older children, as already instanced in the case of tuberculosis, erysipelas, &c., nevertheless infants do not develop these infections so readily as children do after the first or second year of life—in general terms their defensive power is greater. But if it is a fact that the antibacterial defence in infants does not depend on the opsonic content of the serum, and yet at that period their defensive powers are high, is it right to assume that at a later period of life the antibacterial defence does depend on the opsonic content of the serum? May there not be some other interpretation of the variations in the opsonic index than that which is put forward by Wright and which is being so extensively translated into practice?

[3] Allbutt's Medicine, vol. iii., p. 444.

I must confess that while there is much that is interesting and important in the extensive work which is at present being done on opsonins, it would be more convincing to me if the theories on this matter were less complete and simple and if the writings were tinged with a little philosophic doubt. Unfortunately, when we come to study the results of the application of these theories to practice they do not work out as they ought to. In some cases good apparently does result, while in others it is an open question whether the benefit which follows would not have occurred to an equal extent without the vaccination; in many instances, however, and my experience especially concerns tubercle, one cannot convince oneself that the slightest benefit has resulted—in some, indeed, the condition seems to have become worse. Nor even in the cases where benefit has resulted is it clear that the bacteria have been completely eradicated as one would expect if the theory were correct. I think that all we can say about these matters at present is that they are highly interesting from a scientific point of view and that their continued study is highly desirable, but that it is very doubtful if the opsonin theory is the complete solution of the problem. For my own part, I feel satisfied that something is still wanting, and I believe that the discovery of that something will be more likely to be made in connexion with the study of the local conditions of resisting power than of the general conditions of immunity. The time has certainly not yet come when we can with advantage to our patients beat our knives and stethoscopes into hypodermic needles and syringes, discard all our past experience and knowledge, and transform ourselves into immunisators.

THE annual meeting and banquet of the Brussels Medical Graduates' Association will be held at the Garden Club, Franco-British Exhibition, on Tuesday, July 7th, at 7 for 7 30 P.M. Members are invited to bring ladies. All communications should be made to the honorary secretary, Dr. Arthur Haydon, 23, Henrietta-street, Cavendish-square, London, W.

THE ninth annual general meeting of the National Association for the Prevention of Consumption and other Forms of Tuberculosis will be held on Friday, July 3rd, at 3.30 P.M., at Caxton Hall, Westminster, S.W. (nearly opposite the Army and Navy Stores). Lady Aberdeen, Professor Osler, and Dr. C. Theodore Williams will address the meeting.

A Clinical Lecture

ON

EXPERIENCES OF THE SURGICAL TREATMENT OF NON-MALIGNANT AFFECTIONS OF THE STOMACH.

Delivered at the London Hospital on March 18th, 1908,

BY FREDERIC EVE, F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL, &C.

GENTLEMEN,—In bringing before you my experience of operations for non-malignant affections of the stomach I cannot claim that the cases are striking in point of number, but a serious attempt has been made to discriminate between the various conditions for which operation has been performed. This has not been done, as far as I know, in most of the published statistics, especially as regards the most important differentiation between definite ulcer and the group of cases included under erosions, hæmorrhagic, anæmic, and neurasthenic gastritis. It will be submitted further on that in many instances these two conditions are indistinguishable by their clinical symptoms. Where medicine fails, therefore, surgery, with its rough but often more precise methods, must step in. The discrimination to which I allude has been effected by a systematic examination of the interior of the stomach in all cases in which the external appearances of the stomach and duodenum have not afforded a precise indication of the nature of the disorder. In chronic ulcer a definite cicatricial thickening, deformity, or adhesions often, but not of necessity, gives unmistakeable evidence of its presence, but in some cases of acute ulcer of considerable size there is no such evidence. In one case of hæmorrhagic gastritis I found a white cicatrix-like patch on the lesser curvature, but on opening the stomach the corresponding area of mucosa was quite healthy. It may be said that operations are not performed, except in the presence of acute hæmorrhage, for such conditions as hæmorrhagic gastritis, &c., but there can be no doubt that such cases are often included under the common heading of gastric ulcer. I advocated the importance of internal examination of the stomach at the discussion on the surgery of the stomach at Nottingham in 1905, and pointed out the difficulties in diagnosis between ulcer and various forms of gastritis, &c.[1] The method of examination of the stomach adopted has been as follows.

After careful inspection and palpation of the surfaces of the stomach, lesser curvature, pylorus, and duodenum, the stomach is brought out, turned upwards, and an opening made in the meso-colon. Two guide sutures are then placed at points corresponding to the angles of the incision in the posterior wall of the stomach which would be required for a posterior gastro-enterostomy. An incision of from two to three inches in length is made; its edges are raised and opened by means of the guide sutures and artery forceps placed in intermediate positions. A long speculum is passed through the opening towards the fundus, any fluid and mucus is removed with sponges on long sponge-holders, and the whole of the interior of the stomach is carefully examined by means of an electric head lamp. If nothing be found the speculum is withdrawn and a finger passed through the pylorus into the duodenum. Should a gastro-enterostomy be decided on, the edges of the incision in the stomach are held in apposition and a straight clamp is placed on the stomach wall about an inch beyond the edge of the incision. The jejunum is clamped, and the operation of gastro-enterostomy completed in the usual way.

That this method has been carried out systematically is shown by the fact that the interior of the stomach was examined with the speculum or speculum and finger in about 60 per cent. of the cases—i.e., in all the cases of erosion and hæmorrhagic gastritis, in ten out of 19 cases of gastric and duodenal ulcer, in four out of nine cases of stenosis of the pylorus and duodenum, and in one case of gastroptosis with a history of hæmatemesis. In the nine cases of ulcer unexplored the external evidence was conclusive, and in the majority of cases of stenosis with narrowing and thickening of the pylorus the gastrectasis and the inability to invert with the finger the wall of the stomach through the pylorus cases of gastroptosis. Further experience has only confirmed the view as to treatment previously expressed.[6] So far I have not met with a case in which the gastrohepatic omentum was sufficiently strong to enable me to apply sutures by Beyea's original method.

---

[1] Brit. Med. Jour., 1905, p. 774.

The following table comprises all my operations for non-malignant disease of the stomach excepting emergency operations for acute hæmorrhage and operation for hour-glass contraction. The number is 51 operations on 46 patients with three deaths (all in cases of chronic ulcer). This mortality appears high at first sight, but the Mayos give a mortality of 6½ per cent. in their first series of 307 cases of gastro-enterostomy for non-malignant disease,[7] while Kronlein's statistics work out at a mortality of 13·5 per cent.[8]

The operations performed by me were as follows: gastro-jejunostomy, 36; pyloroplasty, 1; secondary entero-anastomosis, 4; gastropexy, 4; and exploratory gastrotomy, 6. The three fatal cases all occurred in patients with extensive chronic ulcer upon whom gastro-jejunostomy was performed. Details of these have already been given.

Gastro-jejunostomy and Gastrotomy: 51 Operations in 46 Cases of Non-malignant Disease of the Stomach.

No. of cases.	Indications.		Number in each class.	Immediate result.		Later results.							Methods used.					
				Recovery.	Death.	Good.	Fair.	Relapsed.	Bilious vomiting.	In hospital.	Died later from stomach or other causes.	Lost sight of.	Posterior gastro-jejunostomy.	Anterior gastro-jejunostomy.	Secondary entero-anastomosis.	Gastropexy.	Gastrotomy.	Pyloroplasty.

	Total operations		—	—	—	—	—	—	—	—	—	—	34	2	4	4	6	1

Gastro-jejunostomy.—The anterior operation was only done twice—in one patient because the stomach was so small and drawn up that the posterior operation was impossible and in another on account of extensive posterior adhesions. In the majority of cases the posterior operation was performed with clamps and sutures, the opening being at the lowest part of the stomach and directed downwards and to the right. I have always been very careful to adjust the efferent end of the jejunum with anchoring stitches, so that there was no chance of kinking. The stoma has been large, two and a half inches or more. Further, I have tried to leave the afferent loop only just long enough to prevent acute bending when its direction was reversed.

My later cases have been done by Mayo's *no-loop operation* which constitutes a distinct advantage. His later statistics give 55 cases operated on by this method with only one death. Two patients developed chronic bile regurgitation of a serious character.[9]

The discussion regarding the relative merits of anterior and posterior gastro-jejunostomy has settled itself by the majority of surgeons adopting the posterior. It need not be entered into here.

What course does the food take after gastro-jejunostomy performed with the pylorus patent? Experiments on animals to settle this question are distinctly helpful, but in some respects unsatisfactory. Cannon and Blake,[10] experimenting on cats by means of bismuth and the x ray screen, observed that the food all passed through the pylorus unless the stoma was situated in the *pyloric segment*. A doubt is thrown on the results of these experiments owing to the stoma being so small—namely, in most instances only from two to two and a half centimetres. For in one experiment in which the stoma was three centimetres long the food passed through both it and the pylorus although the gastro-jejunostomy was situated midway between the two ends of the stomach.[11]

Leggett and Maury[12] fed dogs with a piece of meat wrapped round a bullet to which a string was attached. In one experiment the bullet passed through the stoma along the afferent portion of the jejunum and duodenum back into the stomach. In another experiment, when an anastomosis was effected between the stomach and the ileum just above the ileo-cæcal valve, the bullet passed through the pylorus. This was also the course taken by fat, as shown by the condition of the lymphatics. Nevertheless, dogs on which this operation was performed died from inanition in two or three weeks, although they put on flesh for the first week. Delbet's experiments appear conclusively to show that no food passes through the stoma if the pylorus is patent; but he does not state if the stoma was made in the *prepyloric* or the *central* portion of the viscus—a very important omission. It must, however, be remembered that the very muscular stomachs of dogs and cats cannot be safely compared with the human organ, especially when it is dilated and atonic from disease, or its motility impaired by thickenings about an ulcer; and, further, it is evident that the stoma must serve as an accessory opening in cases of spasm due to prepyloric ulcer or to hyper-acidity. Clearly gastric juice does pass through the stoma, or peptic ulcer would not occur on the jejunum in its vicinity.

It is unfortunate that in the human subject the pylorus, being covered by the liver, cannot be seen. In the case of a thin woman who had some vomiting after posterior gastro-jejunostomy (Mayo's method), performed for hæmorrhagic gastritis, we distinctly saw with the screen the bismuth passing from the lower portion of the stomach into the jejunum in the left flank. At the subsequent operation the afferent jejunum was thin-walled and not distended, and there was no obstruction at the efferent end. In a man observed eight months after gastro-jejunostomy for chronic ulcer at the pyloric orifice the bismuth remained in the stomach about two minutes and then passed through the stoma down the jejunum. These patients were examined in the erect position.

Following the indications derived from the experiments of Cannon and Blake, Mayo recommends that the opening be made in the pyloric portion of the stomach. Cannon himself, however, considered Finney's operation to be the ideal method, as the food is intimately mixed with the pancreatic secretions. Dr. H. O. Cameron,[13] who has recently discussed this question from the point of view of the physiologist, suggests that when gastro-jejunostomy is done for present in four attacks. There was superficial tenderness over the epigastrium and over an area covering the left ninth and tenth ribs posteriorly; also a point of maximum tenderness above and to the right of the umbilicus with some resistance. Free HCl, 0·09. At the operation no definite ulcer but a congested patch of mucous membrane was found on the lesser curvature near the cardiac end. The affected area of mucous membrane was excised, the edges drawn together, and the stomach closed without gastro-jejunostomy. Three years afterwards she was quite well and had no return of her trouble.

A female patient, aged 35 years, had suffered from dyspepsia for 20 years; at the commencement of her illness she had a sharp attack of hæmatemesis which nearly proved fatal. Hæmatemesis also occurred 18 and three years ago respectively. She had pain occurring a quarter of an hour after food and lasting not less than two hours; it sometimes radiated to the back. There was superficial tenderness in front and behind; also a point of deep epigastric tenderness. She had had attacks of vomiting during the last three years coming on about a quarter of an hour after food and relieving the pain. No free HCl in test meal. Exploratory gastrotomy was performed. The stomach was opened and inspected internally and nothing abnormal was found. Previously to the operation the patient had been carefully and for a long period treated medically with unsatisfactory results. The patient is still a chronic invalid.

Digital examination of the interior of the stomach showed that a spastic contraction or spasm of the pylorus existed in three cases.

The first of these patients was a woman, aged 32 years. There was a history of dyspepsia of six months' duration with pain in the epigastrium which became worse after food; distinct epigastric tenderness and vomiting also existed. There had been several attacks of hæmatemesis, once to the amount of a pint. The patient had been fed per rectum for three weeks without improvement. The interior of the stomach was explored with a speculum, but no ulceration of the mucous membrane was found. The pylorus was found to be small and "only admitted the tip of the little finger"; it was tight, rigid, and resistant. There was slight gastroptosis.

The second patient, a female, aged 27 years, had suffered from indigestion as long as she could remember; epigastric pain was experienced immediately after taking food; vomiting occurred usually a quarter of an hour after eating. There was superficial and deep epigastric tenderness. Three distinct and separate attacks of hæmatemesis had occurred commencing first four years ago when the amount discharged was a teacupful. The patient had lost three stones in weight in three years. Medical treatment had been thoroughly tried. The interior of the stomach was examined through an opening in the anterior wall. No ulceration was seen. The mucous membrane was pale and smooth and much dirty brown fluid was present. The pyloric opening barely admitted the tip of the index finger; it felt hard and tense, like a sphincter ani. There was distinct gastroptosis. Total acidity was 0·324.

The third of these patients was a female, aged 27 years, who had had indigestion for two years. There was frequent vomiting which did not relieve pain. There was no history of hæmatemesis or of melæna. The patient had been twice previously in the hospital but medical treatment had given only temporary relief. On passing a finger through an opening made in the stomach wall the pylorus was "found to be tightly closed like a tight sphincter ani." The mucous membrane of the whole of the stomach was examined with a speculum but no sign of ulceration was found.

In two of these cases moderate and in one marked gastroptosis existed. To one accustomed to examine the pylorus with the finger its condition in these cases was unmistakeable. The mucous membrane was quite smooth and there was no cicatricial thickening or external adhesions. The contraction was so firm that one dared not force the finger through for fear of tearing the pylorus. I have on four occasions digitally examined the pylorus in cases of cicatricial stenosis, and do not think it possible to mistake the two conditions. It does not appear likely that the spasm was temporarily due to the irritation produced by the insertion of the finger, otherwise I should have encountered the condition in a larger number of instances. Except in the presence of actual disease, I have found the pylorus quite patulous and easily admitting the passing of a finger into the duodenum. The first of these patients upon whom gastro-jejunostomy was performed subsequently developed vomiting for which a secondary entero-anastomosis was performed. By involuting the anterior wall of the stomach the pylorus was then found to be patulous.

The existence of pyloric spasm in association with hyperchlorhydria has been inferred from the clinical symptoms (Reichmann's disease), but I am not aware that it has previously been actually observed. It probably also exists in cases of ulcer in the pyloric and prepyloric portions of the stomach, although this has been denied.

Practically all the cases placed under the heading of erosions and hæmorrhagic gastritis were referred to me by hospital physicians after medical treatment had failed to relieve the symptoms. The more patients I have operated on the more sceptical I have grown as to finding a definite ulcer in women. The general standpoint regarding the diagnosis of ulcer of the stomach may be gathered from the article by the late Professor Dreschfeld in the last edition of Allbutt and Rolleston's System of Medicine.[4] He writes: "In most cases, however, besides dyspeptic disturbances, there are certain symptoms which may be looked on as characteristic—namely, localised pain in the epigastrium coming on at a variable period after food, vomiting, and hæmatemesis." Further on he writes: "Of the several cardinal manifestations, pain, vomiting, and hyperacidity, the pain with its peculiar features and concomitant hyperæsthesia and muscular hyperalgesia is certainly the most characteristic." Mayo Robson sums up the differential diagnosis as follows: "It may be ordinarily concluded that epigastric pain related to food, vomiting, and localised epigastric tenderness constitute a combination of symptoms pointing to ulcer, but that if hæmatemesis is superadded the existence of ulcer is almost certain." And further on: "If the symptoms do not subside after a few days in bed with care in diet, ulcer is probably present."[5] The experienced authors of these articles were, of course, well aware of the exceptions to these general principles of diagnosis. My series of cases show, however, that the exceptions are exceedingly numerous, that out of 31 cases giving the clinical indications of ulcer in only 19, that is, 63 per cent., was ulceration present

In the light of these facts it is clear that our statistics derived from clinical data as regards the *frequency*, *sex distribution*, and the mortality of ulcer of the stomach require complete revision. In other words, the mortality of actual ulcer is placed much too low. Further, the mortality and after results of operations on cases diagnosed as ulcer must be reconsidered, for unless the interior of the stomach has been examined the true nature of the disease for which the operation was undertaken must in many instances be doubtful.

The majority of the subjects coming under the heading of hæmorrhagic gastritis were females (84 per cent.), usually thin and poorly nourished, who gave a history of stomach trouble for from two to 20 years; in only three patients out of 12 had symptoms existed for under two years. Three had moderate and two distinct gastroptosis. A few were neurasthenic. Superficial and deep tenderness was usually present and hæmatemesis in 84 per cent., the attacks being commonly multiple. In some the amount of free HCl was below the normal.

Results of treatment.—Posterior gastro-jejunostomy was performed in half the cases (i.e., six) and all recovered. The ultimate results were most unsatisfactory and contrasted very unfavourably with the results of operations for ulcer and stenosis. One patient was in perfect health and had gained 12 pounds at the expiration of 20 months; in one the result was fair. Two were cured at first but relapsed to some extent after a year. Two had slight recurrence of vomiting and secondary entero-anastomosis was done, but at the operation no mechanical cause for it was found. In only one case, however, did hæmatemesis recur and then only slightly.

In the remaining six cases gastrotomy only was done. It is interesting to note that one patient continued quite well four years after exploratory gastrotomy performed for hæmatemesis and symptoms of ulcer. A small congested patch of mucous membrane was excised. One patient is a chronic invalid, three were lost sight of, and one is still in hospital.

Gastroptosis.—Time will not permit me to go into my cases of gastroptosis. Further experience has only confirmed the view as to treatment previously expressed.[6] So far I have not met with a case in which the gastrohepatic omentum was sufficiently strong to enable me to apply sutures by Beyea's original method.

[4] Vol. iii., p. 463.

[5] Keen's Surgery, last edition, vol. iii., p. 855.

The following table comprises all my operations for non-malignant disease of the stomach excepting emergency operations for acute hæmorrhage and operation for hour-glass contraction. The number is 51 operations on 46 patients with three deaths (all in cases of chronic ulcer). This mortality appears high at first sight, but the Mayos give a mortality of 6½ per cent. in their first series of 307 cases of gastro-enterostomy for non-malignant disease,[7] while Kronlein's statistics work out at a mortality of 13·5 per cent.[8]

The operations performed by me were as follows: gastro-jejunostomy, 36; pyloroplasty, 1; secondary entero-anastomosis, 4; gastropexy, 4; and exploratory gastrotomy, 6. The three fatal cases all occurred in patients with extensive chronic ulcer upon whom gastro-jejunostomy was performed. Details of these have already been given.

being so small—namely, in most instances only from two to two and a half centimetres. For in one experiment in which the stoma was three centimetres long the food passed through both it and the pylorus although the gastro-jejunostomy was situated midway between the two ends of the stomach.[11]

Leggett and Maury[12] fed dogs with a piece of meat wrapped round a bullet to which a string was attached. In one experiment the bullet passed through the stoma along the afferent portion of the jejunum and duodenum back into the stomach. In another experiment, when an anastomosis was effected between the stomach and the ileum just above the ileo-cæcal valve, the bullet passed through the pylorus. This was also the course taken by fat, as shown by the condition of the lymphatics. Nevertheless, dogs on which this operation was performed died from inanition in two or three weeks, although they put on flesh for the first week. Delbet's experiments appear conclusively to show that no food passes through the stoma if the pylorus is patent; but he does not state if the stoma was made in the *prepyloric* or the *central* portion of the viscus—a very important omission. It must, however, be remembered that the very muscular stomachs of dogs and cats cannot be safely compared with the human organ, especially when it is dilated and atonic from disease, or its motility impaired by thickenings about an ulcer; and, further, it is evident that the stoma must serve as an accessory opening in cases of spasm due to prepyloric ulcer or to hyper-acidity. Clearly gastric juice does pass through the stoma, or peptic ulcer would not occur on the jejunum in its vicinity.

Gastro-jejunostomy.—The anterior operation was only done twice—in one patient because the stomach was so small and drawn up that the posterior operation was impossible and in another on account of extensive posterior adhesions. In the majority of cases the posterior operation was performed with clamps and sutures, the opening being at the lowest part of the stomach and directed downwards and to the right. I have always been very careful to adjust the efferent end of the jejunum with anchoring stitches, so that there was no chance of kinking. The stoma has been large, two and a half inches or more. Further, I have tried to leave the afferent loop only just long enough to prevent acute bending when its direction was reversed.

My later cases have been done by Mayo's no-loop operation which constitutes a distinct advantage. His later statistics give 56 cases operated on by this method with only one death. Two patients developed chronic bile regurgitation of a serious character.[9]

The discussion regarding the relative merits of anterior and posterior gastro-jejunostomy has settled itself by the majority of surgeons adopting the posterior. It need not be entered into here.

What course does the food take after gastro-jejunostomy performed with the pylorus patent? Experiments on animals to settle this question are distinctly helpful, but in some respects unsatisfactory. Cannon and Blake,[10] experimenting on cats by means of bismuth and the x ray screen, observed that the food all passed through the pylorus unless the stoma was situated in the *pyloric segment*. A doubt is thrown on the results of these experiments owing to the stoma

It is unfortunate that in the human subject the pylorus, being covered by the liver, cannot be seen. In the case of a thin woman who had some vomiting after posterior gastro-jejunostomy (Mayo's method), performed for hæmorrhagic gastritis, we distinctly saw with the screen the bismuth passing from the lower portion of the stomach into the jejunum in the left flank. At the subsequent operation the afferent jejunum was thin-walled and not distended, and there was no obstruction at the efferent end. In a man observed eight months after gastro-jejunostomy for chronic ulcer at the pyloric orifice the bismuth remained in the stomach about two minutes and then passed through the stoma down the jejunum. These patients were examined in the erect position.

Following the indications derived from the experiments of Cannon and Blake, Mayo recommends that the opening be made in the pyloric portion of the stomach. Cannon himself, however, considered Finney's operation to be the ideal method, as the food is intimately mixed with the pancreatic secretions. Dr. H. O. Cameron,[13] who has recently discussed this question from the point of view of the physiologist, suggests that when *gastro-jejunostomy is* done for present in four attacks. There was superficial tenderness over the epigastrium and over an area covering the left ninth and tenth ribs posteriorly; also a point of maximum tenderness above and to the right of the umbilicus with some resistance. Free HCl, 0·09. At the operation no definite ulcer but a *congested patch of mucous* membrane was found on the lesser curvature near the cardiac end. The affected area of mucous membrane was excised, the edges drawn together, and the stomach closed without gastro-jejunostomy. Three years afterwards she was quite well and had no return of her trouble.

Tropical Diseases Committee, under the chairmanship, appropriately enough, of Colonel D. Bruce, C.B., R.A.M.C.

The Mediterranean Fever Commission included on the bacteriological and experimental side Professor Tem. Zammit, Government analyst, Malta, Fleet-Surgeon E. A. Shaw, R.N., Major W. H. Horrocks, R.A.M.C., Major J. G. McNaught, R.A.M.C., Captain J. C. Kennedy, R.A.M.C., and myself; and on the epidemiological side Dr. Ralph W. Johnstone, Local Government Board, Fleet-Surgeon F. H. A. Clayton, R.N., and Lieutenant-Colonel A. M. Davis, R.A.M.C., Major T. C. McCulloch, R.A.M.C., and Major J. C. Weir, R.A.M.C., and the work that was assigned to it was the investigation of the path or paths by which infection was accomplished in man and, as an obvious corollary, the suggestion of preventive measures. Work was commenced in Malta in June, 1904, and the last member of the Commission left the island at the beginning of October, 1905. That a certain measure of success attended its investigations and its consequent *recommendations is*, I think, shown by the figures for the following year—1907—in the two tables dealing with the incidence of the disease upon the navy and army respectively, which are so far below the average for previous years as to strike even the most casual observer as indicating something more important than merely an exceptionally healthy year.

During 1904 and 1905 the work of the Commission consisted entirely of individual investigations and comprised the collection of a vast amount of experimental and epidemiological data bearing upon many points in the etiology of the disease. In 1906, when it was my privilege to direct the work as chairman of a combined "working party," the data already collected were tested, and where necessary amplified, classified, collated, and reduced to order, and the gaps unavoidably left during the previous years filled in. And I am glad to have the opportunity of publicly thanking my colleagues for the loyal and whole-hearted support they accorded me in realising the plan of campaign I had mapped out for the summer months.

Much of the work performed and many of the experiments carried out by the Commission yielded evidence of a purely negative character, and valuable though negative evidence always is in enhancing the importance of positive findings it is unnecessary for me to dwell at any great length upon most of it, and it will simplify matters if I first clear the ground by indicating the negative results of the first 12 months of the Commission's work at Malta, dealing in the first instance with the vehicle of contagion.

Air.

Air from wards containing Melitensis septicæmia patients and air from sewers and latrines was aspirated in large volumes through nutrient media; but culture experiments and inoculations into animals alike failed to demonstrate the presence of the specific micro-organism in such situations. In addition to these experiments patients suffering from Melitensis septicæmia in the acute stages breathed directly through tubes of nutrient broth, but the subsequent examination of the medium thus treated yielded completely negative results so far as concerns the presence of the micrococcus Melitensis in the expired air.

Water.

The microbe of this disease has never been found in drinking water. Large quantities of sea water from the Grand Harbour were filtered through porcelain filter candles and the deposit after thorough washing injected into the monkey, but again no trace of micrococcus Melitensis could be detected.

Dust and Earth.

Again numerous examinations were made of specimens of dust and earth taken from localities liable to pollution with excreta, &c., from cases of Melitensis septicæmia, but none resulted in the successful isolation of micrococcus Melitensis—with the single exception of dust from the Mediterranean Fever Commission laboratory, already referred to. In this connexion it must, however, be recorded that in the first place the micrococcus Melitensis is able to retain its vitality and virulence for considerable periods when mixed with dry dust and soil, and in the second that experiments in which monkeys were exposed in a confined space to artificial storms of heavily contaminated dust or soil, and still others in which infected dust was blown directly into the nostrils of the monkey, proved the possibility of infection by contaminated soil in the laboratory. When, however, the conditions that obtain in nature were more closely imitated and dust which had been contaminated with urine derived from Melitensis septicæmia patients and containing the specific micrococci was used, infection did not occur. Nor is this altogether surprising, for the long-continued action of that highly bactericidal reagent, sunlight, in Malta, to say nothing of the enormous dilution any infected dust must be subject to, renders it extremely unlikely that soil or dust remains infective for more than a very short time.

Direct Contagion.

Transmission of this disease by direct contagion has, as I have previously remarked, been constantly denied by all observers, and even Burnett remarked upon the absence of evidence pointing to this mode of transmission. Hence it is no matter for surprise that the micrococcus Melitensis could never be detected in either the breath or the sweat or in the epidermal scrapings from patients suffering from the fever. Skin contact between healthy and infected animals (monkeys) allowing the ready exchange of ectoparasites, and intimate and close in all respects save that the possibility of contact with urine and excremental matters was carefully eliminated, failed to produce the disease in the healthy monkey, but on the other hand infection frequently took place when pollution occurred of the food or person of the healthy subject by infected excreta.

Again, there is a considerable amount of evidence which militates against the conveyance of the disease by fomites in records of cases where, for instance, the healthy mother has nursed and slept with a sick child throughout the course of an attack of Melitensis septicæmia without the parent becoming infected. Finally, in spite of the vast amount of infective material which exists, as has been shown by Bassett-Smith and others, in naval and military hospitals in England, in the shape of invalided patients suffering from Melitensis septicæmia, no cases of this disease have occurred in the medical or nursing staffs of these hospitals other than those directly due to accidental laboratory infections.

[The lecturer proceeded to adduce strong evidence to prove that the micrococcus could be transmitted by sexual congress. This evidence included the examination of prostitutes, an experiment upon a monkey, and observations upon the goat. He then considered at length the possibility of transmission by mosquitoes, detailed a series of experiments which he had made bearing upon the matter, and criticised the case of a laboratory attendant in which it was supposed to pyloric stenosis the stoma should be placed in the pyloric segment where the pressure is three or four times higher than in the cardia, the food is fluid, and the peristaltic movements of the stomach are most active (Cannon). But that in cases of gastric ulcer the stoma should be placed in the cardiac portion where the pressure is low, in order to facilitate the entrance of alkaline duodenal fluid and its admixture with the stomach contents.

There seems no reason to doubt that one of the chief factors in the curative influence of gastro-jejunostomy in gastric ulcer is the neutralisation of the hyperacid gastric contents by the duodenal fluids. Hence Roux Y-shaped junction, entero-anastomosis with the loop operation, and I may add Finney's and Kocher's operations, are contra-indicated in the treatment of ulcer.

In Finney's operation practically an artificial pylorus is formed, through which there is no likelihood of regurgitation; and in Kocher's operation a spur is constructed with the definite object of preventing the contents of the afferent loop from passing into the stomach. Yet all of these theoretically inadmissible operations have been attended by a great measure of success in the hands of various surgeons; hence there must be some other factors at work beyond the neutralisation of the acid stomach contents.

H. J. Paterson[14] found that after gastro-jejunostomy the acidity of the gastric contents was markedly diminished, usually about 30 to 35 per cent. This is due partly to a diminution of the total chlorides secreted, partly to the partial or complete neutralisation of the free hydrochloric acid by the alkaline bile and pancreatic juice. Owing to a certain amount of gastric juice being squeezed through the stoma, it is probable that there is an earlier stimulation of the pancreatic secretion which would give rise to a compensating earlier fall of the gastric secretion.

Some experiments of Fibich[15] tend to show that the mere draining away of gastric juice is not sufficient to cure a chronic ulcer. He artificially produced chronic ulcers in dogs and then by a narrow tube drained the gastric juice only from the lowest part of the stomach. The ulcers did not heal, whereas they healed readily after gastro-jejunostomy.

Other factors leading to cure are the relief of stasis of food and diminution of tension. The stasis accompanying an ulcer at or near the pylorus may be due, as A. F. Hertz states, to reflex inhibition of the relaxation of the sphincter which normally occurs on the arrival of a peristaltic wave.[16] But I have submitted clinical evidence to show that in some cases of stomach disorder there is a definite spasm of the sphincter; and in one case the spasm had disappeared after a gastro-jejunostomy. There is also evidence that the spasm is produced by hyperacidity and is therefore relieved by gastro-jejunostomy. Further, the diminution of tension after gastro-jejunostomy would favour healing of an ulcer by allowing the margins to be drawn over its surface. This is also seen by the effect of gastro-enterostomy in arresting hæmorrhage.

The immediate healing of an extensive ulcer after gastro-jejunostomy was observed by me in the following case:—

The patient, a man, aged 53 years, was admitted with the usual symptoms of chronic ulcer. I operated on Nov. 3rd, 1905, and found a large thickened mass at the pylorus. In gently manipulating the stomach a small bubble of gas attracted attention to a leakage in a crease of the mass near the pylorus. This spot was sequestered with Lembert sutures as far as the thickened tissues would allow, and an omental graft was applied. Posterior gastro-jejunostomy was then performed. It was quite evident that the ulcer was very deep and on the point of perforating. The wound healed aseptically but a stitch gave at its centre, so that the scar there was very thin. Five weeks after the operation I reopened the wound in order to repair the weak spot and found that the mass at the pylorus had entirely disappeared, its place being marked by a piece of adherent omentum. The patient remains quite well. Brennen describes[17] three cases of gastro-jejunostomy in which laparotomy was again performed at different periods for other affections. The ulcers were found healed.

Fibich produced ulcers in the stomach of dogs which showed no tendency to heal. He first ligatured the artery over a definite area of the stomach, then excised the mucous membrane over it, and finally cauterised the surface with hydrochloric acid. Unless all three methods were employed the ulcers healed spontaneously in a few days. Ulcers so produced, however, healed rapidly after gastro-jejunostomy. But it is unnecessary to adduce experiments in support of facts which are demonstrated daily by clinical experience.

To sum up, the following appears to be the present position regarding the choice of operation for non-malignant affections of the stomach. 1. The operation of choice for ulcer is posterior gastro-jejunostomy without a loop. 2. Any form of entero-anastomosis should be avoided in ulcer as it tends to diminish the flow of duodenal contents into the stomach; and it appears to increase the risk of peptic ulcer. 3. Finney's operation is attended with a higher mortality than gastro-jejunostomy, is more difficult, and is contra-indicated in ulcer because the duodenal contents would not pass into the stomach. In stenosis, gastro-jejunostomy gives better drainage and the results are admirable. 4. Pyloroplasty is inefficient in stenosis because the contraction frequently recurs. 5. Excision of a chronic ulcer is rarely feasible and is attended by a high mortality. I should not perform it because my experience tells me that ulcers heal after gastro-jejunostomy, although not placed in the pyloric or prepyloric regions. In five cases of ulcer situated in other parts of the stomach the results of gastro-enterostomy were absolutely good in four, and one weakly man was relieved of pain and indigestion but vomited on rare occasions. The patients were seen at intervals varying from 13 to 36 months after the operation.

In conclusion, I wish cordially to thank my medical colleagues for most of the cases and especially Dr. Bertrand Dawson, who was one of my corresponding physicians at the hospital for several years.

The Milroy Lectures

ON

MELITENSIS SEPTICÆMIA

(MALTA OR MEDITERRANEAN FEVER).

Delivered before the Royal College of Physicians of London on March 5th, 10th, and 12th, 1908,

BY J. W. H. EYRE, M.D., M.S. DURH.,
D.P.H. CANTAB.,

BACTERIOLOGIST TO GUY'S HOSPITAL, AND LECTURER ON BACTERIOLOGY AT GUY'S HOSPITAL MEDICAL SCHOOL; MEMBER OF THE ADVISORY BOARD OF THE MEDITERRANEAN FEVER COMMISSION.

LECTURE III.[1]

Delivered on March 12th.

CHANNELS OF INFECTION.

MR. PRESIDENT AND GENTLEMEN,—I have already remarked upon the dearth of experimental investigation by workers within endemic areas into the questions of the propagation of the fever and the transmission of the micrococcus Melitensis —investigations that one would naturally suppose would have been stimulated by the exact researches of Bruce, but the fact remains that while clinical study of Melitensis septicæmia was prosecuted practically as a routine matter by numerous early naval and military surgeons and the discovery of its specific cause was due to the energy of one isolated and indefatigable research worker nearly 20 years ago, the investigation of the mode of infection required the stimulus imparted by the appointment of a Commission to insure its success.

The following tables, which are amplified in some particulars from the combined table already given, show the wastage in the two services during the past few years of the present century. The tables afford an obvious explanation of the step taken by the then Colonial Secretary, Mr. Lyttelton, in the early part of 1904 in promoting the formation of the Mediterranean Fever Commission after urging joint action by the Admiralty, the War Office, and the Civil Government of Malta. The Royal Society having been approached, consented to appoint an advisory board to supervise the work of the Commission, and did so by nominating a sub-committee of its which abounds in the goat stalls—was on my suggestion tested by experiments carried out by Kennedy on the same lines as the mosquito experiments before detailed but with completely negative results.

Where the milk has been systematically examined in animals that have been experimentally infected the appearance of the coccus in the milk has invariably been a late phenomenon. Goat No. 4, for example, commenced to eliminate the coccus seven weeks after infection; Goat No. 8, three months Goat No. 7, on the other hand, was infected in September, 1904, and, although repeatedly examined, showed no signs of the coccus in the milk up to January, 1906, when, being "dry," she was impregnated. In July, 1906, she dropped two kids and three days later the coccus appeared in the milk and was consistently present up to Sept. 24th, when she was slaughtered, and it is interesting to note that in this case the coccus could not be recovered post-mortem from the spleen, the kidneys, or the lymphatic glands.

THE TRANSMISSION OF MICROCOCCUS MELITENSIS ANTI-BODIES TO THE DESCENDANTS OF INFECTED GOATS.

A further interesting point, and one which has a considerable bearing upon practical preventive measures against the spread of micrococcus Melitensis infection in the goat, is the fact that while an appreciable amount of specific agglutinin is usually transferred from the infected milch goat to its offspring the micrococcus Melitensis itself, minute though it is, does not appear to cross the placenta. Assuming that goat's milk is the infective agent chiefly responsible for the cases of Melitensis septicæmia in man, how do the observed etiological facts accord with this theory?

GEOGRAPHICAL DISTRIBUTION.

It is the fashion for the moment to regard the Maltese goat as the sole carrier, but this assumption is to my mind not altogether warranted. Shaw, in stating that Melitensis septicæmia only occurred in localities in direct sea communication with Malta, implied, if he did not actually state, that the disease was the consequence of the importation of Maltese goats, for these animals, on account of their enormous milking capacity, are in great demand. Still we know quite well that Melitensis septicæmia does exist as an endemic disease in areas where the local milk-producing goat is not of the Maltese breed. No evidence can be obtained from the Customs or Agricultural Department of either India or South Africa that Maltese goats have been imported, yet we know that Melitensis septicæmia in man undoubtedly occurs in India, and Lamb, Forster, and Brayne have isolated the specific coccus from the milk of the common Indian goat, which, although descended from the same parent stock, in no way resembles the Maltese goat. Again, in South Africa, Birt, Statham, and Robertson have similarly isolated the coccus from the milk of the boer brokken, which I am informed by McNaught is nothing like the Maltese goat, which by itself forms into a distinct species.

And now certain general statements acquire a peculiar significance. The Maltese often suggest that the appearance of Crimean veterans in Malta coincided with the appearance or increased prevalence of Melitensis septicæmia. This may well be so. Davy records that the total number of goats, male, female, and kids, amounted to about 3000 in 1833–1844, and probably the advent of large numbers of veterans in the "fifties" marks the date when the increased demand for milk was met by an increase in the number of milch goats, for to-day there are more than 17,000 milch goats alone on the island. Again, Dr. P. D Strachan tells me that in South Africa the rich farmers keep cows but the poorer classes use goat's milk, and the vast majority of his cases of Melitensis septicæmia have occurred amongst the latter class. Still, immediately after the Boer war many who previously used cow's milk were forced to take goat's milk, and the disease was certainly more prevalent then, whereas now that the country is again being stocked with cows the disease is becoming less frequent.

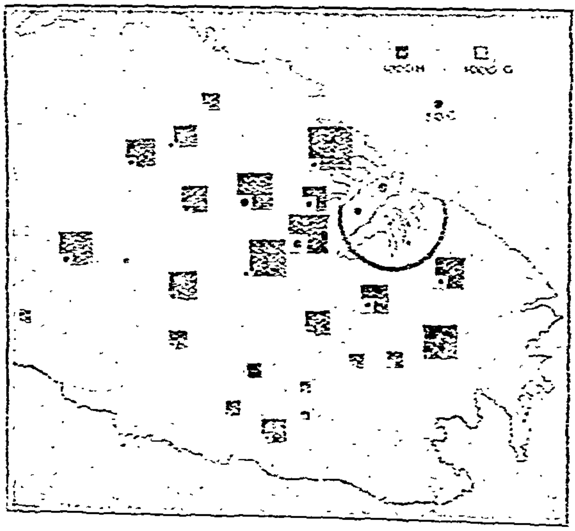
SEASONAL PREVALENCE.

We have already seen that so far as concerns Malta the incidence curve commences to rise in the early part of the summer, reaches a maximum in the hot dry months of July, August, and September, and again falls in the winter time. Now in Malta the goat is usually impregnated in October, November, or December, the gestation period is about nine weeks, the kids are dropped in January, February, or March, and are suckled for three or four weeks. After this time the goat's milk becomes available for consumption. Hence in the height of the summer there is a large quantity of goat's milk available at that period of the year when the largest amount of liquid refreshment is demanded. Now an interesting point which I observed was that a milch goat whose serum gave such a pronounced reaction as to make it absolutely certain that infection with micrococcus Melitensis had taken place failed to excrete the coccus in its milk, which by the way was drying up. This animal was impregnated and on dropping its kid again yielded large quantities of milk, and now the micrococcus appeared in the milk in large numbers and was isolated therefrom with the greatest ease. This observation has since been repeatedly observed, thus suggesting that the milk of infected animals is most dangerous during the period following the birth of the kid—in other words, at the beginning of the summer. This being so we should expect the incidence curve to be at its height during the next two or three months—and we are not disappointed. At the same time it must be noted that the Maltese goat remains in milk for a very long period—often one or two years and sometimes even as long as three years, and this means that a supply of infective material is always to hand and that cases should occur throughout the entire year. We have already seen that this is so.

GENERAL SANITARY CONDITIONS.

Still proceeding in our assumption that goat's milk is the vehicle of contagion, general sanitary conditions should not have much influence on the case incidence. Valetta, sewered, paved, and scavenged, and supplied with excellent water, has a case incidence double the size of that of Mellieha, a rural hamlet innocent of sanitation in the general acceptation of the term. Considering only the area actually built over, the density of population in Mellieha runs to 147,000 individuals per square mile, as compared with 132,000 per square mile in Valetta. When, however, we commence to measure the sanitary condition of a locality in accordance with the amount of infective material—goat's milk—that is available a different aspect is at once presented, as is graphically represented in the sketch-map above (Fig. 4), where the respective sizes of the black and white squares represent the human and goat population ratios in various towns and villages and the size of the black circles and dots represents the ratio of incidence of Melitensis septicæmia in these areas. An excellent illustration of this point is afforded by two neighbouring villages in the suburban area close to the chief town of the island. Hamrun, with a human population of some 12,000, has an average annual incidence of 4·0 per 1000. The goat population numbers 2500 head,

FIG. 4.



Plan of Malta, showing the relative human and goat populations and the incidence of septicæmia Melitensis in the chief centres of population 1000 H = 1000 humans. 1000 G = 1000 goats. 50 C = 50 cases of septicæmia Melitensis. The sizes of the squares and circles are proportional.

have occurred. He stated that the possibility of the mosquito acting as a *carrier* of the micrococcus was completely proved and offered the following suggestion as a possible though exceedingly rare means of infection by this agency :—]

A mosquito, having fed on a case of Melitensis septicæmia in the acute septicæmic stage whose blood contained large numbers of the cocci, settles 48 hours later upon a healthy individual and proceeds to insert its proboscis into the skin. The mosquito before feeding massages its abdomen with its hindermost pair of legs and extrudes a mass of bloody excrement, inclosing the coccus in a virulent condition, upon the skin surface only a few millimetres distant from the puncture made by its proboscis. The bitten individual, when alive to the fact that a mosquito is feeding upon him, rouses, frightens off the mosquito or kills it *in situ*, and then probably proceeds to scratch thoroughly the infective excrement into the site of the minute wound and, following a successful inoculation, an attack of Melitensis septicæmia ensues. Such a sequence of events is well within the range of possibility, and yet the necessary combination of factors is sufficiently uncommon to render this method of infection as rare as the experiments upon monkeys would indicate.

Food.

Zammit, who had approached the subject of Melitensis infection in a purely scientific spirit on his appointment to the Commission, had already attempted the infection of the most important animal in the Maltese domestic economy—viz., the goat—not only by the usual methods but, more important still, by feeding experiments carried out upon selected healthy animals. No constitutional effects were produced, but one month after administration of the growth from one agar tube culture of micrococcus Melitensis mixed with the food specific agglutinins were detected in the blood serum and steadily increased in amount as time went on. This experiment was repeated with similar results, and as months afterwards the serum reaction was found to be still present, although somewhat diminished in amount, a systematic examination of the blood, the urine, and the milk was entered upon and Zammit was able to show that the specific micro-organism could be isolated from each and all of these fluids. Next, a batch of six presumably healthy goats was purchased as a preliminary to further experiments, but it was found that specific agglutinins were present in the serum from five of the animals, while the specific coccus was present in the blood of two of them, in the urine of two, and in the milk of four. In the meantime Zammit, at the suggestion of Carruana Scicluna, the head of the Public Health Department of Malta, instituted an inquiry into the natural infection of the goat by bacteriological examination of the spleen of all goats slaughtered in the public abattoir and the testing of the blood for specific agglutinins. 46 goats were thus examined and the micrococcus isolated from the spleen of one, while specimens of serum from seven yielded a positive agglutination reaction in dilutions of at least 1 in 80, thus showing that naturally infected goats were fairly common. In view of these facts the Commission thereupon engaged in an extended series of observations as to the evidences of infection in the Maltese goat, and as a result of their inquiries applied in round numbers to 2000 animals—one-tenth of the goat population of the island—found that 40 per cent. yielded positive agglutination reaction pointing to present or past infection, and that 10 per cent. secreted milk containing the micrococcus Melitensis.

Another important piece of work carried out by Zammit as the result of his observation that specific agglutinins were present in the goat's milk as well as in its serum was the modification of the sedimentation test to render it immediately applicable to the testing of suspected milks, for it was subsequently found that the specific coccus was never found in the milk from which appreciable amounts of agglutinin were absent. The importance of the goat as carrier of micrococcus Melitensis and of its milk as an infective food at once necessitated the careful study not only of the course of the infection in the goat when naturally acquired but also of many points in its natural history, habits, and general economy.

This wide distribution of goat "carriers" leads one to inquire what is known as to the origin of the goat. Both naturalists and palæontologists agree that the early ancestor from which the domestic goat has descended is the Persian wild goat (capra ægagrus)—the pasang ("rockfooted") of the Persians—and that the many varieties now existing in Europe and elsewhere have been evolved by the action of environment and natural selection through many ages, aided by crossing with local allied species either naturally or by human design. The present-day range of the original Persian goat is extensive—from the western side of Sind and Afghanistan through Baluchistan and Persia to the hills of Asia Minor, particularly the Taurus range, but though even up to classic times it was widely distributed throughout the Grecian Archipelago it is now limited so far as Europe is concerned to the island of Crete. There is not the least doubt that this wild goat of the East was early domesticated and accompanied prehistoric man in his western migrations through Palestine, the peninsula of Sinai, and Northern Africa on the one hand, and through the Grecian and Italian peninsulas and Southern Europe, westwards and northwards on the other, for we find ample evidence that the Swiss lake-dwellers of the stone age possessed goats in greater abundance than sheep. Simultaneously with this westward migration the goat was taken southwards down the east coast of Africa until it reached the portion of Southern Africa subsequently occupied by European races.

Now I am decidedly inclined to the opinion that Melitensis septicæmia is primarily a disease of the goat, which had its origin in the Persian hills, and which accompanied that goat on its world-wide wanderings, and which has remained potentially active for man so long as its host preserved its original habits in barren rocky countries in the tropics and subtropics where pasturage is of the scantiest and consists chiefly of shrubs and weeds. When, however, the goat reaches those temperate climes and abundant pasturage which are so pre-eminently suitable to the cultivation of the cow that its lactiferous capabilities fail to rival those of the last-named animal, and selective inbreeding is in consequence neglected, the micrococcus no longer finds a suitable habitat in the caprine mammary glands and rapidly disappears.

The transmission of the disease from goat to goat may obviously take place along any one or more of several channels, for I have already pointed out that this animal is susceptible to infection by the micrococcus Melitensis in the laboratory by cutaneous, subcutaneous, intraperitoneal or intravenous inoculation, or by feeding.

Cutaneous or subcutaneous inoculation is probably responsible for a large number of infections, the contagion being carried from goat to goat by way of the goatherd's hands when soiled with infective milk, more especially as laboratory experiments show that a comparatively small number of cocci are sufficient to produce infection.

The technique adopted by the Maltese milker closely resembles that of his English *confrère*, and consists in lubricating his own hands and the outside of the udder with some of the foremilk. When a number of goats have to be milked in rapid succession the lubricant obtained from the first goat will serve for perhaps some half-a-dozen goats; with the seventh goat a fresh supply of milk is taken for the same purpose, and so on. Now, given that Goat No. 1 or Goat No. 7 is passing micrococcus Melitensis in its milk, it is obvious that at any rate Goat No. 2 or Goat No. 8, as the case may be, stands a very good chance of becoming infected by a process of subcutaneous inoculation.

[The lecturer proceeded to describe an experiment in which he had shaved somewhat roughly an area of skin over the mammary gland of a healthy kid, and then rubbed in two cubic centimetres of infected milk containing some 5600 micrococci. On the fifteenth day blood drawn from the goat's ear contained agglutinins, and three weeks after inoculation the goat was killed and a careful post-mortem examination was carried out, with the result that the specific organism was recovered from the spleen and inguinal glands. He proceeded :—]

The successful result attending this cutaneous method of inoculation—a method closely resembling that employed in Jennerian vaccination—renders it extremely probable that convection by the flies, which positively swarm in the goat-pens, may play a part in the transmission of the infection from goat to goat. In this connexion it must be remarked that the udder of the Maltese goat is extremely large and pendulous; many an animal is compelled to walk very warily to avoid treading on its own udder, and superficial abrasions are frequently present on the udder where it has been dragged along the ground in walking.

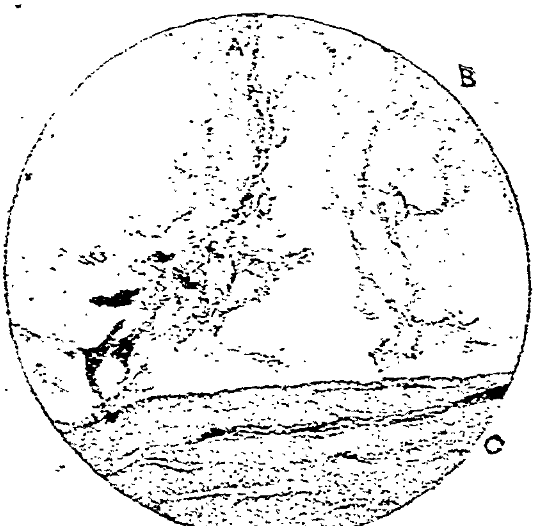
The possibility of the transmission of the coccus by means of blood-sucking flies, other than by mechanical conveyance upon body or limbs—for example, by Stomoxys calcitrans crystals; numbers of such groups of tyrosin crystals are seen *in the blood-vessels, in the smaller and larger septa* dividing and subdividing the muscular bundles, as also in the scant connective tissue between small groups of muscular fibres. The muscular fibres themselves appear without the normal transverse striation, are swollen, some are breaking down into particles of fibrilli and into granular matter, and contain numerous empty spaces—gas bubbles. The presence *of the tyrosin crystals and the structural alterations* just described clearly indicate putrid decomposition of the proteid constituent of muscle. Tested with litmus the reaction of the tainted muscle is distinctly alkaline.

On dissecting and comparing different hams, some less, some more tainted, it becomes manifest that in all cases the decomposition is most pronounced at and around the knee. In the distinctly miscured ham the condyles of the femur, the patella, the condyles of the tibia, the crucial ligaments, the semilunar fibro-cartilage, and the parts adjoining the capsule (connective tissue, tendon, and muscle) are quite green and the smell of putrid decomposition extremely pronounced. In the less miscured hams the discolouration is here less pronounced; it does not amount to green, but it is nevertheless distinct and the smell is pronounced.

From the dissection and comparison of the different hams which I had the opportunity of examining I have no hesitation in affirming that the taint starts about the knee and gradually progresses from here towards the femoral and gluteal regions.

2. *The cause of the taint.*—The essential cause in all tainted hams examined was one and the same species of cylindrical microbes, and one species only, of which the morphological and biological characters will be presently described. In conformity with what has been said, this microbe is found in great numbers in the tainted parts, the more pronounced the taint the more copiously present is the microbe; in discoloured (grey-green) swollen muscular fibres the microbe is present in almost continuous lines between and parallel to the fibres, here and there in smaller or larger clusters; it is present in the intermuscular connective and fat tissues in very great numbers and from these tissues it invades the muscular tissue itself (*Fig. 1*). In less tainted—i.e., less discoloured—parts the microbe becomes less numerous and in slightly miscured parts its numbers fade away; in fact, there can be little doubt that the number of these microbes determines the intensity of the taint. In and about the knee, on the other hand, whether the taint is pronounced in the whole ham or whether it is only pronounced about the knee, all the parts constituting this latter—condyles, patella, ligaments, semilunar cartilage, capsule, and the loose connective tissue and tendinous tissue around—are covered with almost continuous masses of the microbe. The free surfaces of all parts within the articulation are covered with a slimy moist film which when transferred to a glass and looked at under the microscope is composed of a continuous mass of the microbe. This, of course, is quite in conformity with what is said above about the knee being the starting and principal point of the taint, for in this part the microbe has evidently had opportunity to multiply to an enormous extent and gradually, by its continued growth and lengthening and multiplication, to pervade farther and farther into the ham. In addition to this distribution of the microbe there is this other fact—viz. (as we shall presently see), the microbe we are dealing with is capable of causing by its activity in albuminous soil the same malodorous decomposition (putrefaction) as occurs in the miscured ham. We have, then, sufficient reason for maintaining that the microbe, by its growth, multiplication, and chemical activity, is the real cause of the changes that characterise the taint or decomposition of the ham.

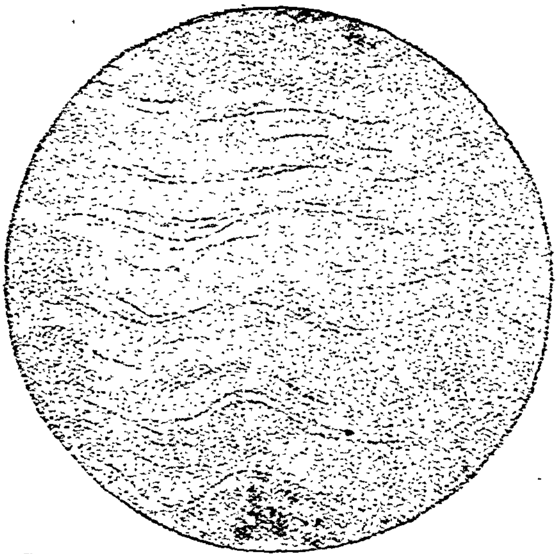
FIG. 1.



Miscured ham. Muscular tissue invasion. A, Large septum containing masses of the bacilli (black). B, Fat tissue. C, Muscular fibres between which are continuous streaks of the bacilli (black). × 125.

3. *Morphological and biological characters of the microbe.*—As has already been mentioned, the microbe is present in the tainted parts as cylindrical rods; in the intermuscular tissue, loose connective and fat tissues, and in the tendons numerous chains and filaments of these rods occur (Fig. 2); in the slimy film covering the inner surfaces of all parts of the articulation the microbe is present as short or long cylindrical rods and as filaments of considerable length. Some of these filaments are merely linear series of cylindrical rods, others show a subdivision or segmentation only here and there, so that the greater part of the filament appears uniform and unsegmented. In the accompanying Fig. 3 the size and appearance of the microbe in stained preparations are well shown. When measured in a specimen like that shown in Fig. 3 the length of the microbe on the average is 3–5μ, the shortest 1·6μ, *but some* are longer, 12–14μ long; some are considerably longer and, as shown in Fig. 2, some filaments are even many times longer than that; the microbe is 0·4μ in thickness and is straight or curved; the ends, which in most individuals are more or less rounded, seem in the filaments where the rods are arranged as short or long chains almost straight cut.

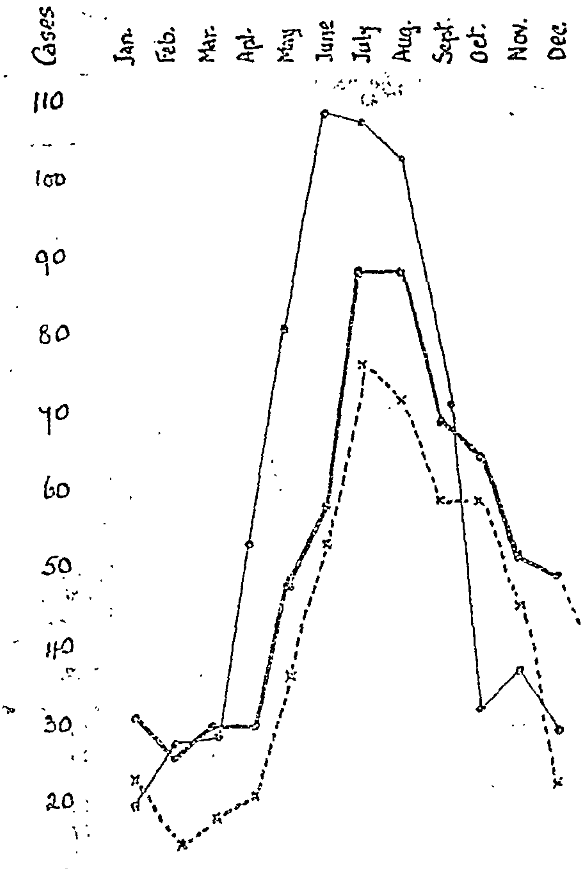
FIG. 2.



Tendinous tissue around knee. Miscured ham. Between the tendon bundles are the bacillary filaments. × 500.

The microbe is not possessed of motility—that is to say, its progressive *growth from* a given point is not helped by any locomotion, as is the case with some other microbes capable of causing decomposition. These latter by their locomotion can rapidly invade fresh fields and pastures new where they again multiply rapidly and whence they send out further hosts. The microbe we are dealing with, not possessing locomotion, must rely for its progress on its gradual multiplication; in this invasion its power of sanitary authorities into conflict with the usually uneducated and often violently prejudiced native of the agricultural class, and it is uncertain how far recommendations under this head will, from the diplomatic point of view, commend themselves to the civil authorities. In the event of such measures being adopted, the ordinance upon which they are based will need to be administered with great firmness and tact.

FIG. 5.



Incidence of septicæmia Melitensis amongst the civil population of Malta. Thick line = average for 1896–1905. Thin continuous line = cases for 1906. Thin dotted line = cases for 1907.

In the first place, it is essential that all the goats in the island should be registered and some method should be employed of numbering by means of stamped metal discs (such as is already carried out in the case of dogs), which will afford a ready means of identification of individual animals. Next, repeated analyses of samples of milk, taken at regular intervals, must be made in respect to every milch goat by medical officers of health (who need not be bacteriological experts) specially detailed for this purpose, at three, four, or more district "centres" where laboratories for the application of the Zammit milk test must be provided. Further, samples of the milk from each animal, giving a positive reaction with this test, must then be sent to the central laboratory in the Public Health Department at Valetta for bacteriological examination for the demonstration of the presence of micrococcus Melitensis. So far the suggested measures are simple in theory and by no means costly in practice; nevertheless, unless carefully handled, the Maltese goatherd will offer considerable opposition to their execution.

Next, such infected animals as are found from time to time to be yielding milk containing the specific micro-organism of Melitensis septicæmia must be segregated. This measure will necessarily be more expensive in operation, though, considering the importance of the issue at stake, not unduly so.

The total number of goats to be dealt with amounts approximately to 20,000, of which probably at least 2000 are infective, so that provision should be made on a liberal basis for dealing with a possible 5000 animals during the first year's work. When an animal is definitely shown to be yielding infective milk it should be at once seized by the sanitary authorities and transferred to the lazaretto, or some other "pound" to be subsequently established, the owner being compensated on a scale comparable to that employed in Great Britain when infective animals (e.g., in pleuro-pneumonia, tuberculosis, &c.) are seized by the public health authorities, and the milk-stall from which it has been removed should be disinfected and lime-washed at the expense of the civil authorities. As, however, the flesh of infected goats, &c., is harmless when cooked, considerably more than half of the animals thus seized could be slaughtered, the viscera destroyed, and the flesh sold for consumption—a proceeding which would materially lighten the cost of these preventive measures. Moreover, as the progeny of infected milch goats is itself uninfected at birth, the seizure and destruction of infected animals should be combined in the case of the more valuable animals—the specially good milkers, &c., with a modification of the "Bang process" for the reproduction of tuberculous herds, under the direct control of the Public Health Department, at special breeding farms where the selective in-breeding, which has rendered the Maltese milch goat such a valuable animal, could be continued under skilled supervision. This process, devised by Professor Bang of the Copenhagen Veterinary College, as applied to tuberculous herds, has already been carried out with marked success in Denmark, Hungary, and the United States of America, and it appears probable that in dealing with the micrococcus Melitensis infection in goats the whole of the infective animals thus seized would be replaced by healthy animals in the course of three or four years. Here, again, by the sale of yearlings a considerable return might be effected. While the capital sum required to organise and carry out all these measures in an efficient manner is greater than the civil authorities in Malta could readily devote to the purpose, enormous economies would be effected by the disappearance of Melitensis septicæmia from the Maltese islands, which would amply justify an appeal to the Imperial exchequer—assuming, of course, that Malta retains its present importance as a base for our sea and land forces.

Although certain powers are already available under existing ordinances it would probably be preferable to introduce a new ordinance for the express purpose of stamping out Melitensis septicæmia from the goats of the Maltese islands, and I am confident that this much-to-be-desired end might readily be attained if the Imperial Government could but be induced to regard assistance in the matter as its obvious duty to its Maltese dependencies.

ON THE NATURE AND CAUSES OF TAINT IN MISCURED HAMS (BACILLUS FŒDANS).

BY E. KLEIN, M.D., F.R.S.,
LECTURER ON ADVANCED BACTERIOLOGY AT ST. BARTHOLOMEW'S HOSPITAL MEDICAL SCHOOL.

I WAS requested by Mr. Alfred Marsh of Brierley Hill, Staffordshire, to investigate and to report upon the cause of taint which occasionally affects hams during the curing process. The results of this investigation in their essential points are described in the following. For permission to make this publication I have to offer my best thanks to Mr. Marsh. In Mr. Marsh's factory the hams undergo the "dry curing" only—i.e., they are treated with dry salt and saltpetre, which are applied repeatedly on the outer surface of the ham, no other method of salting, injection, or pickling in fluid being used.

1. *Character, appearance, and distribution of the taint in the ham.*—The miscured ham denotes its character by its distinctly putrid smell. Taking a ham that is markedly tainted and examining the muscular tissues, it will be seen that the muscles are more or less discoloured; in slightly tainted portions the characteristic red tint of well-cured muscle is changed to a pale or dirty grey tint, while in the strongly tainted parts the colour varies between a dirty grey and dirty green. In the latter parts the muscular tissue is swollen and soft, more like a jelly. Making a section through the tainted muscle and examining it under the microscope, the first change that attracts our attention is the presence of small linear clumps of crystals—tyrosin

A NOTE ON THE EARLY TREATMENT OF PROTRUDING INCISOR.

By J. F. COLYER, M.R.C.S., L.D.S.R.C.S. ENG.,
DENTAL SURGEON AND LECTURER ON DENTAL SURGERY TO CHARING CROSS HOSPITAL; SURGEON AND DEAN TO THE ROYAL DENTAL HOSPITAL, LONDON.

PROTRUSION of the upper incisor teeth is a deformity only too often seen amongst the children of the present day, and it is one on which dental practitioners are by no means in agreement as to the best method of treatment. In a few cases the protrusion of the teeth is the direct result of the use of the baby comforter, of lip sucking, or a somewhat similar habit; in the majority of instances, however, the protrusion is accompanied by an abnormal growth of the jaws and dental arches. It is to this latter class I propose to refer.

Now, although there is a certain amount of obscurity about the etiology and pathology of these cases, there are, however, certain facts generally accepted, and to these brief allusion will be made, as they have an important bearing on the question of treatment. In the first place, attention must be drawn towards a well-recognised fact—namely, that the teeth themselves are formed during the first three years of life, and are arranged, one might say, in a crowded manner in the substance of the bone. If the teeth could be taken and fixed in the mouth the arch of the jaws would be found quite inadequate for the correct arrangement of the teeth. If orderly development of the jaws takes place then by the time the teeth erupt there is room for their proper and correct arrangement. This orderly development is under modern conditions interfered with, mainly by lack of function of the jaws, with the result that there is an interference with the growth of the body of the jaw. What is the result? A struggle takes place on the part of the teeth for room in the jaw, and *either* the incisors and canines together, at times the premolars, are crowded into irregular positions, or the anterior teeth are pushed forwards, causing superior protrusion. Why in the one case simple crowding results and in the other superior protrusion is not clear.

This lack of development would seem to affect the maxilla and mandible unequally. Clinical evidence shows that the maxilla suffers more frequently and more severely than the mandible, and for this reason the growth of the mandible is influenced by the function of mastication, whereas that of the maxilla is in addition considerably influenced by the proper performance of the nasal function—in other words, in nasal obstruction the antrum and premaxilla *do not* develop properly, and this interferes in a marked manner with the proper growth of the maxillæ. In the majority of cases of superior protrusion I consider the major lack of development is in the maxilla and *not* the mandible. This is, of course, the reverse of the position taken by those who lay so much stress upon the question of occlusion. In a few, but a very few, cases the protrusion is apparent not real—that is to say, the maxillæ are normal, but the mandible is deficient in development.

Another point to be considered is the rapid increase in the protrusion of the teeth as the child approaches the age of 12. This is due to the action of the canines in erupting. The four incisors may be pushed forward, the teeth maintaining a good curve, or the laterals may be forced under cover of the centrals, giving rise to what is sometimes styled "a rabbit-shaped" mouth.

To sum up, the points to be emphasised are: 1. *Protrusion* of the superior teeth is usually accompanied by some lack of development of the bone, producing a want of relationship between the teeth and the jaw. 2. The maxilla is more often affected than the mandible. 3. The protrusion gets rapidly worse with the eruption of the canines.

What line of treatment do these facts indicate? Clearly, extraction of teeth to relieve the crowding and still further extraction at an early age. This method is at variance with the views of many practitioners who urge that no attempt at correction should be made until after the eruption of the second permanent molars and canines.

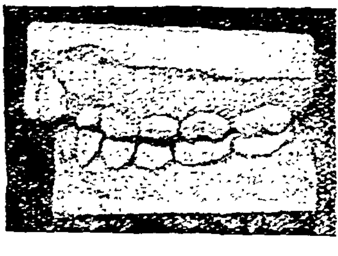
Let us consider for a few moments the disadvantages of delaying treatment; the advantages it is difficult to see. 1. The canine in erupting will move forward, increasing the protrusion of the incisors and also the crowding of their roots. 2. When treatment is commenced the canine must be retracted by mechanical means, and in this process instead of moving bodily back and so giving true relief to the pressure in the front of the mouth it will only swing backwards, leaving the upper end of the root in much the same position as it erupted. The result of this will be a constant tendency for the protrusion when corrected to relapse, simply because the roots of the anterior teeth will remain more or less crowded. 3. The retraction of the incisors will occupy a greater length of time, partly because there will be more protrusion to overcome and partly because the alveolar process will be more resistant. 4. Owing to the prolonged mechanical treatment disorganisation of molar and premolar occlusion often ensues.

If treatment is carried out before the eruption of the canines these teeth will erupt well back, pressure will immediately be taken off the incisors, the protrusion will not increase, and the amount of mechanical treatment will be only slight. Still further, the teeth come into good alignment and the tendency to relapse is reduced to the minimum. If early treatment is adopted the room *for* the canines should be made directly the lateral incisors are in place by removing the unerupted *first premolars. For* this operation an anæsthesia of longer duration than ordinary nitrous oxide is necessary. After a little practice ethyl chloride will usually be found sufficient but if the case is likely to be difficult then ether should be used.

The most suitable instrument for removing the teeth is a pair of upper root forceps with long slender blades. The deciduous molar is first removed. In attempting the removal of the premolar the inner blade of the forceps must be kept well inwards, the blades being thrust well upwards, and extractive force made in an inward direction. The occluding surface of the erupting premolar is directed slightly inwards and unless the *precaution suggested* is taken the inner blade of the forceps impinges on the occluding surface and does not grip the inner aspect.

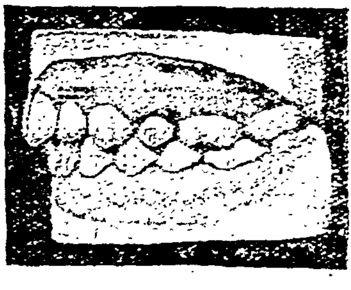
With regard to the treatment of the wound, the best course seems to be to keep the mouth clean by means of an antiseptic wash. If much swelling ensues the use of hot fomentations will generally bring relief.

FIG. 1.



Case 1. Before treatment.

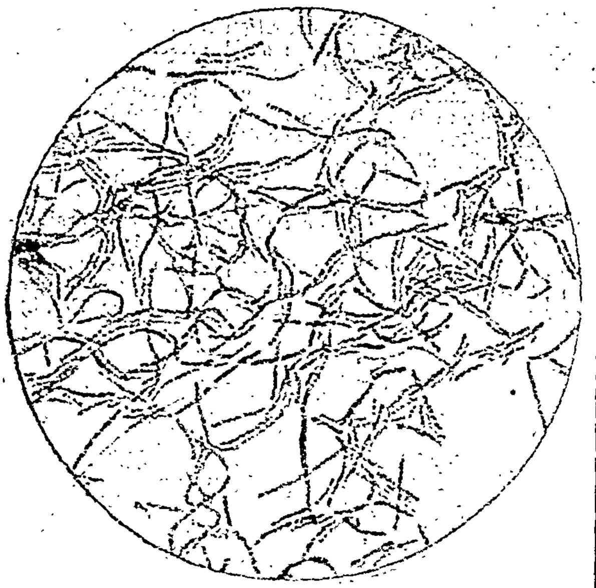
FIG. 2.



Case 1. After treatment.

After the removal of the premolars the case is left alone until the canines have fully erupted, the patient being made to keep the lower lip in front of the upper teeth. Occasionally this simple expedient is sufficient to bring about a complete cure of the case. The effect of the removal of the pressure of the canines on the incisors is interesting. The laterals *soon show* a tendency to travel backward, pointing to a complete relief of the crowding of the anterior teeth. The incisors are eventually brought in elongating and forming linear chains and filaments must obviously be of great help to it, since thereby it is capable of much sooner reaching neighbouring parts than if, like some other microbes, it had the tendency to become localised more or less by forming aggregations, nests, or circumscribed colonies. The above filaments and chains separating ultimately into the component rods, and these again elongating and dividing and thus forming new chains and filaments, furnish the microbe with the power of gradual extension and progress.

FIG. 3.



Culture of the microbe in glucose broth. × 1000.

The microbe is an obligatory anaerobe—that is to say, it cannot grow when freely exposed to air (oxygen); it requires for its growth to be in the depth of tissues deprived of oxygen. In this respect it is like some other microbes which have their home in the alimentary canal, some of which are connected with putrefactive changes occurring in the intestines. Like many other anaerobic bacilli the microbe we are dealing with is Gram-positive but it differs from many of the intestinal anaerobic bacilli in that it is not possessed of motility, as already stated, and neither in suitable artificial culture nor in the tainted ham does it show anything that might be considered as comparable to ordinary spore formation. Most of the known anaerobes occurring in excremental matters, manure, &c.—i.e., in the alimentary canal—e.g., bacillus enteritidis sporogenes, bacillus œdematis maligni, bacillus cadaveris sporogenes (bacillus putrificus coli), bacillus tetani—are capable of forming spores. Neither in the tainted parts (joint, muscle, and connective tissue) have I been able to detect anything in the nature of such spores except once when I found some few of the bacilli which presented the appearance of a terminal body like that of a spore. Nor have I been more successful with cultures. I have carefully examined such cultures after seven, 14, 21, and 30 days in which copious growth of the microbe had taken place, but I have not been able to detect spores in the bacilli or their filaments.

In order to produce artificial culture of the microbe special procedures have to be employed.

1. The microbe shows no growth whatever when planted on the surface of suitable media, being strictly (obligatory) anaerobic; it has therefore to be planted and kept under anaerobic conditions—i.e., in media from which all air (oxygen) had been boiled out and which after inoculation are kept in an atmosphere devoid of oxygen.

2. No growth is produced when the planting is done on ordinary nutrient gelatin, on ordinary nutrient agar, or in ordinary nutrient broth, but glucose gelatin and glucose broth, and particularly glucose pork broth, were found suitable for the production of growth.

3. For the production of artificial growth under the above two conditions small traces of the original material (taken direct from the tainted portions of the ham) are of no good; I have made dozens of cultures in this direction without any result; but using large pieces of the original materials success was obtained. The easiest way for obtaining positive result was to use for the planting bits of the size of a pea of the tissues from the knee—bits of crucial ligaments, bits of the semilunar cartilage, a good slice of the surface of the condyles of the femur or of the tibia, a bit of the capsule. I have failed to produce growth if, for instance, I planted of the slimy superficial fluid of the interior of the joint what could be taken up with the point of a lancet; when a similar amount is used for stained cover-films and is examined under the microscope it is found that it is really an almost continuous layer of the bacilli, such, for instance, like that represented in Fig. 3. And yet notwithstanding this enormous host of bacilli introduced into the culture medium, no result—i.e., no growth—was produced. From this it seems clear that many of the bacilli must be dead and that therefore only few of them buried within the tissues had escaped death and were capable on planting out of starting a new progeny. This would mean, then, that the bacilli not forming spores were not able to preserve their vitality owing either to the continued germicidal or inhibitory action of the curing matter or to the poisonous action of their own chemical products, this latter being a well-known fact obtaining in cultures of non-sporing microbes. I am inclined to attribute to this latter cause the chief devitalising action, since the same takes place also in the artificial cultures of our microbe—viz., that when growth is well established in the culture and in order to propagate it by a new culture, several drops of the turbid culture material have to be used for the successful planting; merely a loopful, although containing thousands of the microbic chains and filaments, produces no results. This is obviously only explained by what we already mentioned—viz., that many of the microbes rapidly die by the action of their own chemical products.

I have not been able to obtain cultures if the infected media are kept at temperatures below 50° F. No successful cultures are produced if the infected culture media are kept at blood-heat temperature (37° C.), but positive result was readily obtained at 20° C. (70° F.). The quickest success was obtained in glucose pork broth, kept for from two to three days at 20° C. (70° F.); in glucose beef broth, or in glucose gelatin, it generally took about five days to a week.

The general nature of the culture is this, that the microbe in its growth invariably forms masses of chains and filaments; the filaments are mostly twisted, wavy, curved, or more or less spiral; by shaking the culture medium (glucose broth) the chains and threads are liable to separate and to break up into shorter parts—individual bacilli or short chains—but there nevertheless always remains a majority of threads, some separate, others remaining matted together into convoluted masses. I have examined successful glucose gelatin cultures in which besides the presence of small and large flocculi (convolutions of threads) many parts were uniformly cloudy by the growth; examining under the microscope these cloudy portions it is seen that the gelatin is uniformly permeated by single threads twisted and curved. In glucose broth the growth is noticed as a voluminous whitish-grey more or less slimy deposit at the bottom of the fluid like a mass of cotton wool, and when it is examined under the microscope is seen to be a convoluted aggregation of filaments. The rest of the fluid remains quite limpid until it is shaken, when the mass breaks up into small and large flocculi and into separate threads.

The glucose gelatin is not liquefied by the growth for many weeks. After about eight weeks at 20° C. the gelatin becomes transformed into a thick, syrupy fluid and there is always great evolution of gas which pervades all parts of the gelatin as small and large gas bubbles. In the glucose broth culture the evolution of gas is not so easily noticed as most of the gas escapes to the free surface, but drawing up into a capillary pipette some of the fluid culture a lot of minute gas bubbles become rapidly visible, thus showing that the gas was present in the fluid in a dissolved state, and separated when mechanically disturbed. All cultures have an offensive putrid smell exactly like the tainted parts of the ham. The reaction of the culture is distinctly alkaline.

Milk is not changed by the growth, but it acquires a nauseating, most offensive odour. Subcutaneous injection of either the tainted muscle itself or of large doses of culture of the microbe into healthy guinea-pigs causes no change of the animals' condition, either locally or constitutionally.

I propose for this hitherto undescribed microbe the name Bacillus fœdans.

St. Bartholomew's Hospital.

be also rotated by means of the ligatures, bands and spurs being attached to the individual teeth in the position necessary to bring about the required movement. There is no mere speculation as to the correct position of the teeth and the size of the arch and the amount of expansion desired, as means have been devised of measuring the teeth and from the measurement obtained the size of the arch and position in which to place the teeth can be almost accurately calculated and varies according to the size of the teeth in each individual case. The geometrical principles on which the movements of the jaws are based have also been studied and a fairly accurate basis for the discovery of the correct size of the arch in any case, with the teeth in position, can be obtained, and measures in a straight line from the distal buccal cusp of the right six year molar to the distal buccal cusp of the left six year molar from about $2\frac{1}{100}$ths–$\frac{48}{100}$ths of an inch in the upper jaw, and from $1\frac{81}{100}$ths–$2\frac{22}{100}$ths of an inch in the lower jaw. The expansion arch if intelligently employed is wonderfully efficient in enlarging the arch in any direction and in the control of the teeth moved individually or collectively. It furnishes the most natural appliance to secure normal occlusion, for by it we can regulate the entire dental apparatus—something impossible in the use of the innumerable appliances that have been devised for the correction of symptoms only without regard for the laws of occlusion.

In treatment of cases of the second class where the lower arch is distal to normal the expansion arches and clamp bands are inserted as described. The force is then exerted from one or more small rubber ligatures which engage on sheath-hooks attached to the upper expansion arch in the canine region and over the ends of the tubes on the clamp bands on the lower molars. The force is reciprocal, acting directly on the molars, the result being to move the lower molars mesially and the upper molars distally. As the lower first molars are carried forward the bicuspids and canines are pushed in advance of them; the lower incisors are also carried forward, being ligated with wire ligatures to the anterior part of the expansion arch. After the upper molars have been moved distally into full normal occlusion it will be found that a space exists between the molars and second bicuspids. The clamp bands on the upper first molars are then removed and smaller clamp bands placed on the second bicuspids. The force of the rubber ligatures is again exerted in order to carry distally the bicuspids. A wire is made to engage the upper first and second bicuspids in order to effect their movement at the same time. Whilst moving the upper molars and bicuspids the arch is kept free from the incisors so as to allow the full force to come upon the former. When the teeth are well back into correct mesio-distal relations with the lower the arch is gradually adjusted to allow the force to be received by the upper incisors and canines, which in turn are soon moved into correct relation with their antagonists. The arch in both upper and lower jaw is usually inserted with a correct amount of outward spring to effect at the same time the required expansion. For the treatment of cases of the third class the above order with regard to the rubber ligatures and clamp bands is reversed.

To retain the teeth again the best device is probably a fixed apparatus. The simplest retainer for a single tooth is made by soldering a round wire to the labial or lingual surface of a band and cementing the band on the teeth. Several bands may be united for the same purpose to retain more than one tooth. An expanded arch can be retained by a stiff wire along the lingual sides of the teeth and soldered to a band on the first bicuspid and first molar teeth on each side. The incisors which have been moved forward or retracted are retained by a similar wire running along the lingual or labial surface of the teeth and soldered to bands on the first bicuspid teeth. The period of retention varies according to the amount of movement brought about and also upon the age of the patient, and may be any length of time between nine and 18 months. The nearer the attainment of normal occlusion in the correction of any case of malocclusion the less need there is for retention, the normal influence of the inclined planes as well as the other forces governing normal occlusion acting to preserve the positions obtained. With normal relations of the arches established, the jaws, the muscles of mastication, the cheeks and lips, and the facial lines will be in best harmony with the type peculiar to the individual, as a perfect profile requires normal occlusal relations.

Upper Wimpole-street, W.

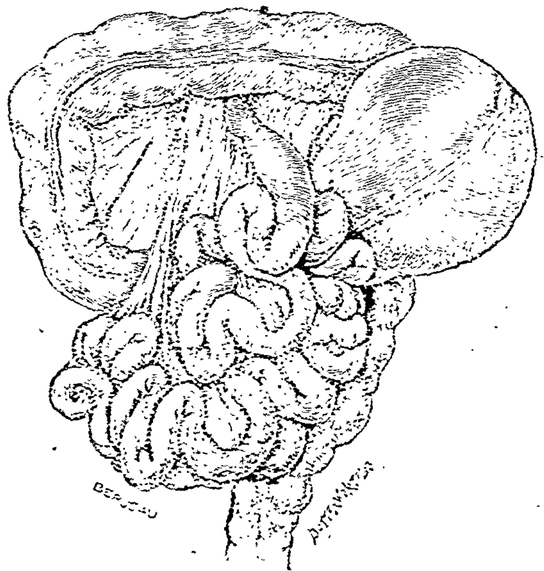
ON A CASE OF MIGRATION OF THE CÆCUM PRODUCING OBSTRUCTION OF THE ASCENDING COLON.

BY JOHN BLAND-SUTTON, F.R.C.S. ENG.,
SURGEON TO THE MIDDLESEX HOSPITAL, LONDON, W.

(*From Notes by the Surgical Registrar to the Middlesex Hospital*, SOMERVILLE HASTINGS, F.R.C.S. Eng.)

WHEN the cæcum is provided with a long meso-cæcum it may lie in any region of the abdomen; perhaps the most unusual situation for a displaced cæcum to occupy is the left kidney pouch, behind the mesentery. When a cæcum migrates in this way it gives rise to a puzzling set of symptoms, as the following case will serve to illustrate.

A poorly nourished man, 48 years of age, came under my care in the Middlesex Hospital for abdominal pain and vomiting. A week before admission he had been seized suddenly with griping pains in the abdomen, particularly on the right side; these were sufficiently severe to confine him to bed and were followed by anorexia and vomiting. The vomit was bile-stained and watery. On admission the abdomen was somewhat distended, but moved evenly on respiration; no tumour could be felt and there was not much tenderness. The temperature ranged about 100° F. As these signs indicated the existence of intestinal obstruction, cœliotomy was performed. On making a free median incision several ounces of purulent fluid escaped and the intestines appeared inflamed and moderately distended. Attention was first directed to the right iliac fossa, but the cæcum and appendix were not there. A tense band of gut extended from the right extremity of the mesentery upwards and to the left, overlapped by mesentery and coils of small intestine; when traced upwards it led to the ileo-cæcal junction in the left kidney pouch. A loop, consisting of the last few inches of the ileum and the ascending colon with the cæcum and appendix, had been twisted on its own axis through half a circle and displaced upwards and to the left. The cæcum had become adherent in its new situation and when drawn down a large necrotic area with two perforations was seen, through which liquid fæces issued. The necrotic area was excised and the edges of the hole thus made in the gut were approximated with sutures. The free fluid in the abdomen was swabbed out, a large rubber tube was introduced into the pelvis, and the incision was closed with silk sutures. The man died 16 hours after the operation.

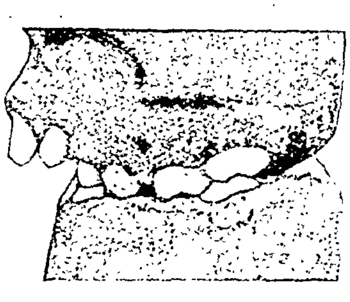


A diagram to represent the position of a cæcum which had undergone torsion and after passing behind the mesentery occupied a position in front of the left kidney.

The patient whose clinical history and fate I have described came under my observation in October, 1906. I was interested and much puzzled by the condition found at with a simple mechanical contrivance, the teeth being retained in position until after the second permanent molars have erupted.

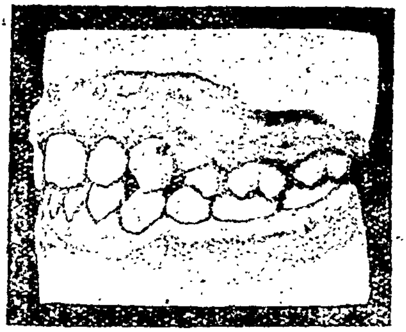
With regard to the treatment of the lower teeth, one is guided by the condition existing. If crowding is present then the first premolars are removed, but the time for removing them is left until the commencement of eruption of the canines. But little is gained by removing the mandibular premolars at quite an early age, as is the case in the maxilla.

FIG. 3.



Case 2. Before treatment.

FIG. 4.



Case 2. After treatment.

Cases of superior protrusion treated in the way suggested do extremely well; there is no tendency to recur, the amount of mechanical treatment is very little, and the occlusion of the premolars and molars is good. In the figures are shown the models of two cases before, and the same cases after, treatment.

Much has been said about the tendency of this type of irregularity when treated to relapse. There will be little if any tendency to relapse if we can: (1) insure that the lower lip in occlusion passes in front of the upper incisors; (2) insure that the lower incisors do not press unduly upon the backs of the upper incisors; and (3) prevent crowding of the upper incisors and canines. The less we are unable to overcome these difficulties the greater will be the tendency to relapse.

THE TREATMENT OF MALOCCLUSION (ORTHODONTIA).

BY H. C. HIGHTON, L.D.S. R.C.S. ENG., D.D.S. PENN.

THE fundamental principle of orthodontia is that we have a thorough understanding of normal occlusion and all that the term implies. It is necessary to appreciate the normal relationship of the teeth of the mandible with those of the maxilla, how each individual tooth is dependent not only upon its fellows mesially and distally but upon the opposing teeth and all the teeth collectively to maintain harmony, and then only is it possible to understand thoroughly any of the various types or deviations from the normal. From a study of skulls of past and present races normally the mesio-buccal cusp of the upper first molar occludes between and buccally to the mesio- and disto-buccal cusps of the lower first molar. The mesial incline of the upper canine occludes with the distal incline of the lower canine, the other teeth if regular being then normally related; it is quite necessary for the first molars and the canines to be correctly related, otherwise malocclusion and alteration of the facial lines must result.

Classification.—The classification of *malocclusion* as suggested by Dr. E. H. Angle[1] is based upon the variation from the harmonious relationship known as normal occlusion, three great classes being represented, the first having normal mesio-distal relation of the arches, the second having the lower arch distal to normal in its relation to the upper either unilaterally or bilaterally, and the third having the lower arch mesial to normal in relation to the upper either unilaterally or bilaterally. The great majority of cases of malocclusion belong to the first class, the second class comprising a small percentage, and the third a still smaller percentage of the various existing cases of malocclusion. In the first class the teeth may be in any possible position of malocclusion which would be consistent with a normal antero-posterior relationship between the arches of the teeth. For example, any of the incisors and canines may be in labial or lingual occlusion, the bicuspids or molars in buccal or lingual occlusion. There may be protrusion of the anterior part of the upper arch or retrusion of the anterior part of the lower arch without disturbing the normal antero-posterior relationship.

The treatment in all cases of malocclusion is therefore simply the placing in harmony of the inclined planes of the teeth and establishing of normal occlusion. The principle underlying this treatment, which is advocated in "orthodontia," is expansion of the arch as opposed to extraction and the consequent narrowing of the arch and alteration of the facial lines. Many people come under our observation with mutilated mouths and abnormal facial expressions that have been brought about by extraction of the teeth, often to prevent some developing form of malocclusion. The ideal to be kept in view is the attainment of normal occlusion which presupposes the full complement of teeth.

There are, briefly, at least three important reasons for the expansion of the dental arch. First, to permit malposed teeth to assume their correct alignment; second, to improve the facial lines; third, to endeavour to broaden the nasal chambers and so increase the capacity for nasal breathing. The latter is naturally a very important consideration, as it concerns the future health and welfare of the patient. Expansion of the dental arch to be most effective should be done as early in life as possible; gradual force exerted while the patient is young encourages the natural development of these parts. In treatment it is also necessary to rotate the teeth, move them labially or lingually, mesially or distally, any of which movements are most easily accomplished by means of the clamp band, expansion arch, and wire ligatures. As the ultimate success of the treatment naturally depends upon the ease of retention of the teeth in the corrected position—viz., in normal occlusion—it will readily be understood how essential it is to retain the full number of the teeth, since only by that means can the inclined planes of the teeth be placed in correct normal relationship which if accomplished will simplify to a very great extent the method and length of time of the retention. Extraction, therefore, should always be avoided if possible, as not only does it destroy the possibility of obtaining an ideal result but also renders more difficult the final retention.

We find that in the majority of the cases of malocclusion the arch is narrow, the teeth crowded together, overlapping, and malposed to a greater or less degree, and the forces which acted in bringing about this malformation are equally powerful in maintaining and exaggerating this condition when once it has been established. Orthodontia aims at placing every tooth in its normal position in relation with its fellows and those of the opposite arch and retaining them in that position until the muscles, alveolus, and tissues of the neighbouring region have accommodated themselves to the altered conditions. The means usually employed to bring about this result is a fixed appliance which is arranged as follows: clamp bands are secured to the first upper and lower molar teeth; these consist of a band with a horizontal tube on the buccal side and a nut and screw on the lingual side to tighten the band to the required size. The ends of an elastic wire arch, the expansion arch, are inserted into the buccal tubes and the arch is ligated to the teeth by means of fine wire ligatures, the expansion being brought about by the arch having an outward spring, while the ligatures can be occasionally tightened. The teeth may to the middle of the sternum, but the absence of cardiac murmurs and the failure to discover any morbid lesion on post-mortem examination sufficient to account for it rendered its explanation difficult without entering into the uncertain region of speculation. A certain degree of cardiac dilatation and neurasthenia, resulting from malnutrition of the heart muscle, may be adduced as a not improbable cause of this symptom. The severe pains so frequently complained of in the præcordial area in cases of acute anæmia have been thus explained by Burney Yeo[4] and there is no reason to doubt that the anæmia of scurvy, which is usually of a severe type, may give rise to similar symptoms, despite the inability to appreciate any definite physical lesion by means of the stethoscope.

---

[1] Treatment of Malocclusion of the Teeth, 1907.

The phenomenon of *pyrexia* in scurvy has apparently not been particularly emphasised in medical literature. In the cases under discussion, however, an elevation of temperature was the rule rather than the exception. In the milder forms of the disease the temperature for days ranged from 99° to 101° F., in the more severe it frequently rose to 103°, while some of those suffering from intercurrent affections died in a state of hyperpyrexia. There is reason to believe that, apart from the effects of the general vascular disturbance, the absorption of the products of extravasated blood was the efficient cause of continued pyrexia. Hæmorrhagic effusion into the tissues has given rise to fever in cases of simple fracture of the femur, the temperature in one case remaining high for ten days, as has been recorded by Volkman.[5] The experience of surgeons during the South African war confirms this fact, for in cases of bullet wounds of the chest the temperature often remained high long after the wounds had healed. This proved to be due to unabsorbed blood clot in the pleural cavity and, as a consequence of this observation, it is now practically an axiom of military surgery that aseptic hæmothorax may be an efficient cause of pyrexia.

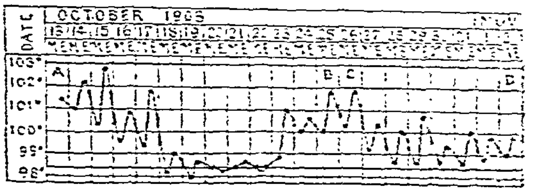
Blood examination.—The method here pursued was that elaborately described by Sir A. E. Wright, in which standardised dilutions of sulphuric acid are used.[6] The maximum value found by this method for the alkalinity of the normal serum is most simply expressed by the fraction $\frac{N}{25}$. This means, in simple language, that a serum which is exactly neutralised by an *equal* volume of a 25-fold diluted normal acid would correspond in alkalinity to a 25 fold diluted normal solution of alkali. Once only has the above result been obtained. In the case of 13 other normal persons the alkalinity varied between the values $\frac{N}{30}$ and $\frac{N}{45}$, while the average alkalinity of the blood has been placed at $\frac{N}{35}$. The blood in 22 of the cases referred to was examined by Lieutenant-Colonel Birt, who was at that time in charge of the Military Hospital Laboratory, Bloemfontein, and the result of his investigations was as follows. In two cases the measure of alkalinity of the blood serum was $\frac{N}{30}$, in six $\frac{N}{35}$, in eight $\frac{N}{40}$, in one $\frac{N}{45}$, in three $\frac{N}{50}$, in one $\frac{N}{60}$, and in one $\frac{N}{70}$. In other words, the alkalinity falls below $\frac{N}{45}$ in five only out of 22 cases; it is average normal, $\frac{N}{35}$, in six, still higher, $\frac{N}{30}$, in two; while the average for all the cases is equivalent to about $\frac{N}{42}$.

With regard to the results of post-mortem examination, one fact need only be emphasised—namely, the constant presence of ante-mortem thrombi in the heart and great blood-vessels.[7] These in some cases were so large as to add considerably to the weight of the heart, while in others they were found to have plugged up the aorta and pulmonary artery at their points of origin. This phenomenon was somewhat disconcerting, considering what prevailing theories might have led one to expect. The results of Lieutenant-Colonel Birt's examination certainly point to a diminished alkalinity of the blood; but the diminution is by no means so serious as the gravity of the disease would lead one to expect.

Sophie and Moraczenski[8] found the alkalinity of the blood reduced in anæmia and chlorosis, and one might legitimately infer that the results obtained from blood examination in the above-mentioned cases were sufficiently explained by the anæmia, often profound, which is always associated with scurvy. But a reference to the condition of the blood as found on post-mortem examination again adds to one's perplexity in view of authoritative statements as to the diminution of blood coagulability in this disease. In pneumonia and other debilitating diseases thrombi are frequently formed in the heart during the death-agony, presumably owing to the waning power of the ventricular systole, and it is obvious, from the results just stated, that the same thing happens in scurvy in even a more exaggerated form. Professor Stockman has stated that the blood in scurvy coagulates normally, and the facts just referred to are not unfavourable to his conclusion.[9]

Treatment.—The usual hospital diet for a native consisted of half a pound of mealie meal three times a day. To this was added for each scorbutic patient a daily allowance of four ounces of lime-juice and two ounces of sugar. Three months' experience of such a diet proved unsatisfactory—in fact, disastrous. Within that period nine kaffirs died and the survivors had made very little progress towards recovery. Calcium chloride, in doses of ten grammes thrice daily, was given, but in view of the increasing mortality its use was soon abandoned. At this stage it was thought advisable to reconsider the dietary, as the utmost freedom was allowed in the choice of fresh food and vegetables. Half a pound of fresh meat was added to the daily dietary of each patient; it was partly broiled and partly utilised as raw-meat juice. In addition to this each individual received ten ounces of fresh vegetables, four ounces of jam, and four ounces of fresh fruit, while a mixture consisting of citrate of potassium and infusion of calumba was given thrice daily. The good effects of this treatment soon became evident. In about ten days patients who had been too weak to stand when admitted to hospital began to walk, hæmorrhagic swellings gradually disappeared, and the fever abated. Further, of the 13 deaths referred to two only fall within this period, but they occurred at so early a stage of it that it may reasonably be inferred that the change in treatment was too late to benefit them.

In consequence of such good results it was decided to test the value of fresh meat alone as a remedy in scurvy. Accordingly, a kaffir boy (Maguta), who presented the signs and symptoms of the disease in a marked degree, was selected for this special diet. His gums were spongy, the last lower molar teeth were surrounded by tags of bleeding tissue, and the hard palate was covered with small petechiæ. He could hardly stand when admitted to hospital. On the fourth day after his admission, although his temperature registered 101° F., he was put on the diet already described. To this two pints of sterilised milk were added, as a "placebo." By the sixth day the temperature had fallen below normal and at this stage the quantity of fresh meat was increased to two pounds per diem. The temperature again rose slightly and remained high for a few days; but when the mouth and gums were examined on the twelfth day it was found that the tags of bleeding tissue had disappeared



A, Meat and raw-meat juice. B, Sponginess of gums almost disappeared. C, Bread, milk, and vegetables added. D, Potassium citrate mixture. The patient was discharged from hospital on Nov. 11th; from Nov. 2nd to that date his temperature varied between 98° and 99°, except that on the morning of Nov. 8th it fell to 97°. The patient was the Kaffir boy Maguta whose case is described above.

the operation; my interest was increased by reading a valuable contribution by Mr. Jonathan Hutchinson, jun.,[1] on Volvulus of the Entire Small Intestine and Ascending Colon. This communication was founded on a case which is in its leading features like the one which I have endeavoured to describe, but Mr. Hutchinson fortunately saved his patient; he also made his paper valuable by furnishing an analysis of nine other similar cases of volvulus. Mr. Harold W. Wilson has since published an account of a case of migration of the cæcum producing obstruction of the ascending colon which occurred in St. Bartholomew's Hospital in the practice of Mr. Harrison Cripps[2] which resembles my case in its main features.

This complication connected with the cæcum is worth the attention of surgeons, as descriptions of it are not to be found even in monographs dealing with intestinal obstruction. Its importance is obvious from the fact that the majority of the patients in whom it has occurred have died. Judging from a study of the recorded cases it would appear that the chief variations in the degree of the displacement depend upon the extent to which the twist or rotation involves the mesentery. For example, the extreme condition occurs in patients in whom the intestines, including the third part of the duodenum, the cæcum, and ascending colon, are attached to a common mesentery. When such an anatomical condition exists, and it is a recognised anomaly, the whole of the small intestines, the cæcum, and ascending colon may be concerned in the volvulus. In my patient the parts implicated included the terminal 12 inches of the ileum, the cæcum with the vermiform appendix, and half the ascending colon. The condition of the third portion of the duodenum was not noted either at the operation or post mortem. During the operation the absence of the cæcum from the right iliac fossa was detected as soon as the abdomen was opened, because it is with me a matter of routine in operations for intestinal obstruction to ascertain the condition of the cæcum as the primary step after exposing the abdominal viscera.

I think the fatal nature of this form of volvulus is mainly due to delay on the part of hospital patients in seeking advice. The signs are not so urgent as in acute obstruction of the small intestine, and when the patients are admitted the obstruction may not be absolute, for enemata bring away small quantities of flatus. Abdominal distension is not a marked feature. In the case under my own care the diagnosis seemed to lie for the first few hours between perforation of the appendix and intestinal obstruction; then the indications of obstruction prevailed. The signs of perforation were not counterfeit, for, as has already been mentioned, there were two holes in the wall of the cæcum. The man was gravely ill at the very hour of his admission.

NOTES ON SCURVY IN SOUTH AFRICA, 1902-1904.

By DUNCAN MACKENZIE MACRAE, M.A.,
M.B., CH.B. GLASG.,
LATE CIVIL SURGEON, SOUTH AFRICAN FIELD FORCE.

THE earliest information which emerges from the twilight of antiquity in regard to scurvy is perhaps that supplied to us by Pliny who states that a disease which was cured by eating a certain vegetable prevailed in the army of Germanicus. Thucydides, who has been styled "the greatest historian that ever lived," described the horrors of the plague at Athens (B.C. 430) in words of lurid fire; but, unfortunately, no such writer has left us a record of scurvy, as it existed among the ancients, although we may well believe that the conditions under which they often lived and waged war were favourable to outbreaks of the disease on a large scale. There is evidence, more or less reliable, that in mediæval times it frequently broke out in beleaguered towns and garrisons, but it is only when we approach the records of early maritime enterprise that we stumble upon anything like a definite description of its nature and occasional virulence. The sailors of Bartholomew Dias (1486), Vasco da Gama (1496), Raymond (1591), and Lancaster[1] (1601), in their early voyages round the South African promontory, suffered more or less from scurvy. The best accounts of it, however, are to be found in the narratives of such navigators as Jacques Cartier, Dampier, Anson, and Captain Cook. Lancaster and Captain Cook, in their longer voyages, proved the efficacy of lemon juice as a remedy in the disease and Dampier records with some enthusiasm the benefits resulting to his crews from a short stay on the island of Juan Fernandez (1683), where they were fed on vegetables and goats' flesh, "a regimen which," to use his own words, "proved very beneficial." Anson's[2] account, however, is less glowing, for when he landed his scorbutic sailors on the same island in 1739 he relates how, although many greatly benefited eventually, "the disease continued unabated for 20 days" and in some cases assumed an intractable form. The first clear and scientific record of scurvy is to be found in the writings of Lind (1797); and it is largely due to his insight and the efforts of Sir Gilbert Blane that the disease has been banished from the navy and mercantile marine.

It is not at present intended to do more than briefly to summarise and comment upon the phenomena of the disease as observed among the kaffirs during, and for some time after, the South African war. Through the courtesy of the officers of the Royal Army Medical Corps, the writer, while stationed at the Military Hospital (No. 8), Bloemfontein, during the years 1902–04, was permitted to take charge of all kaffirs admitted suffering from scurvy, and it is on the observations then made, in conjunction with Lieutenant-Colonel C. Birt, R.A.M.C., and Captain J. W. West, R.A.M.C., in regard to its symptoms, behaviour under treatment, and the condition of the blood on examination that the following remarks are based.

Two hundred natives suffering from scurvy were treated in No. 8 Hospital during the above-mentioned period, and of this number 13 died. But before describing the most striking symptoms, although the writer is unwilling to encumber this article with exhaustive references to the literature of the subject, it may be well to mention the several theories which have been at different times advanced in explanation of this disease. Garrod believed that it was due to a deficiency of potassium salts in the food. Ralfe ascribed it to the absence of vegetable acids, such as malates, citrates, and lactates, causing diminished alkalinity of the blood. Sir A. E. Wright describes it as "an acid intoxication which eventuates in a defect of blood coagulability" and some have supposed it to be due to a specific micro-organism. The most recent suggestion, due to Professor Torup of Christiania, is that the disease is a kind of ptomaine poisoning resulting from eating tainted meat. The experiences of Mr. Jackson and others in the Arctic regions, and the experiments of Dr. R. J. Harley in support of their observations—viz., that those living exclusively on fresh raw meat escaped the disease under the most trying circumstances, while those supplied with lime juice suffered from it—would seem to throw discredit on the time-honoured view that fresh vegetables and lime juice were efficient preventives against it.[3]

The pendulum of scientific thought was thus suddenly swung to the other extreme—a not uncommon error in the history of human speculation; but it must be admitted that the problem of the etiology of scurvy still remains unsolved.

Signs and symptoms.—These, in the main, conformed to the descriptions found in text-books. Petechial ecchymoses of the skin, hæmorrhagic swellings in the neighbourhood of joints (more especially the knee-joints), ulcers of the buccal cavity, and a brawny induration of the anterior aspect of the legs were the prevailing signs of the disease. Serious complications, such as hæmothorax and sero-sanguinolent effusions into the pericardial sac, were not uncommon and always terminated fatally; but the spongy condition of the gums, usually regarded as an infallible sign of scurvy, was by no means a constant characteristic in the cases under consideration, so that some difficulty was at times experienced in arriving at a correct diagnosis. It was absent even in some of the most serious cases admitted to hospital. A striking feature in the disease was the almost universal complaint of *pain in the chest*. This pain was usually referred

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF STRANGULATED MECKEL'S DIVERTICULUM IN A RIGHT INGUINAL HERNIA.

BY A. F. STOKES, M.B., CH.B.,

HOUSE SURGEON, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THE patient, aged three months, was admitted to the Hospital for Sick Children, Great Ormond-street, on May 16th, 1908. He had been breast-fed and was always a healthy baby except for occasional attacks of abdominal pain, during which the legs were drawn up and the stomach seemed full of "wind." There had been no attacks of vomiting, no diarrhœa, and no passage of blood or mucus by the bowel. A rupture had been first noticed two days before admission to hospital which could not be reduced by the practitioner who had attended the child. The lump had gradually got larger and the skin over it had become red. The baby had vomited once two days previously. He had always been constipated but the bowels opened naturally on the day of admission. Micturition was normal. The patient was a pale, feeble-looking child, with drawn face and sunken eyes. The heart and lungs were normal, the pulse was about 100, and the temperature was subnormal. There was a tense swelling in the right inguinal region, tightly gripped by the external ring and extending into the scrotum, where the testis was felt to be enlarged and hard below the tumour. Squeezing the testis caused no pain; the left testis was fully descended.

At the operation the right inguinal canal was cut down upon, the external oblique split up, and the sac, which was very œdematous, was exposed. On being opened it was found to contain a loop of small intestine adherent by filmy adhesions to the sac wall; there was very little fluid in the sac. At the upper part of the neck there was a strangulated club-shaped Meckel's diverticulum originating from a separate loop of gut and nipped at its base. The internal oblique was nicked so that the diverticulum and loop of gut might be delivered—there was a small perforation at the spot where it had been constricted. The base was clamped, tied off with silk, the diverticulum was removed, and the peritoneum was brought over the stump by purse-string suture. The testis, which was gangrenous, was removed. Radical cure was performed after Bassini's method.

With regard to the after-history of the case the child at first was rather collapsed, but on the next day he was doing well. Unfortunately, vomiting and diarrhœa began on May 18th, but this was checked by usual remedies. On the 20th vomiting began again and the child died in a few hours from exhaustion. No post-mortem examination was obtained.

I am indebted to Mr. H. Stansfield Collier, in whose ward the patient was, for permission to publish this case.

NOTE ON A CASE OF SUICIDAL CUT-THROAT.

BY A. BANKS RAFFLE, M.D. DURH.

THE following case is of interest as presenting many features that we usually look for in homicidal cases.

The patient, a miner, aged 54 years, after inflicting serious injuries on his wife and child, cut his own throat with a razor and died in eight minutes (roughly) from the time of committing the act. He was a man of violent temper who indulged intemperately in alcohol, but apparently he was sane. The wound was very severe, extending in a perfectly transverse direction across the neck to the border of the sterno-mastoid muscle which was slightly divided on either side, and it divided the thyro-hyoid membrane and severed both external carotid arteries just above their origin from the common carotid. The wound on section was bow-shaped, being deepest in the middle part and tapering at each end, extending down to the body of the vertebra at its deepest part. There were no wounds except the one mentioned.

The case is of interest, since the wound presented more of the features of a wound that was inflicted by another than a self-inflicted wound. The man's determination was remarkable; on being caught he levered the edge of the razor both upwards and downwards, attempting also to injure one of his captors.

Westoe, South Shields.

DERMOID CYST OVER THE MASTOID PROCESS.

BY P. MAYNARD HEATH, M.S. LOND., F.R.C.S. ENG.,

ASSISTANT SURGEON TO THE EVELINA HOSPITAL FOR SICK CHILDREN, SOUTHWARK BRIDGE-ROAD, S.E.

THE patient, a boy, aged four years, had suffered from a swelling behind the left ear since birth. It had gradually increased in size and at the time of examination was half an inch in diameter. The swelling was cystic and freely moveable under the skin and over the deeper structures. The cyst was removed and was found to be lined by a simple stratified epithelium and to be filled with cheesy material. There was no deficiency in the underlying bone or periosteum. The case is recorded as dermoid cysts in this situation seem to be somewhat uncommon.

ROYAL SOCIETY OF MEDICINE.

SURGICAL SECTION.

Reduction of an Old Subcoracoid Dislocation of the Humerus by Excavating the Glenoid Cavity through a Posterior Intermuscular Incision.—Cystic Tumour of the Suprarenal Body successfully Removed by Operation.—Compound Fracture of the Arm.—Ununited Fracture treated by Planting Small Fragments of Bone between the Ends.

A MEETING of this section was held on June 16th, Mr. J. WARRINGTON HAWARD, the President, being in the chair.

Mr. W. G. SPENCER read a paper on the Reduction of an Old Subcoracoid Dislocation of the Humerus by Excavating the Glenoid Cavity through a Posterior Intermuscular Incision. He said that the forcible reduction of old dislocations at the shoulder had been often described as a successful measure, but the use to which the patient could afterwards put the limb or whether he had thereby been predisposed to a recurring dislocation had generally been passed over without mention. The employment of forcible measures had frequently caused additional injury, many dying from rupture of the axillary artery. That method would only now be practised in a limited fashion. Some cases, for one reason and another, remained unreduced, the patients making what use they could of the mobility of the scapula. Kocher's method of reduction had been recently reviewed and defended by Bach.[1] Excision of the head of the humerus in order to regain mobility formed the subject of a paper by Sheild.[2] In the paper, and in the discussion which followed, a number of cases were mentioned and since then that operation had often been practised. Some form of anterior incision had been adopted. The operation was difficult because the operator had to cut freely through displaced and altered structures which could not be well identified; the circumflex nerve was always in danger of being injured, as were also the other axillary structures. There was left a wound cavity in which blood tended to collect and to break down. Although the result obtained might be good as regarded mobility there might be little strength in the arm. Lord Lister in his presidential address to the Hunterian Society in 1890 described two cases of bilateral dislocation for which he had performed arthrotomy. After freeing the head from its muscular attachments he reduced the dislocation by the aid of pulleys. Keetley[3] advocated arthrotomy and included a full history of the subject. Lister's method of arthrotomy, aided by extension by pulleys, left the and that nothing remained in the mouth indicative of scurvy beyond a few petechiæ on the hard palate. The temperature still remained elevated and the legs were slightly swollen and tender, but the patient could now stand with ease. Fresh vegetables were added to the meat diet and in two weeks' time the patient, having made a good recovery, was discharged from hospital. It may be added that the results obtained in many cases by substituting a liberal supply of fresh milk, bread, and vegetables for meat were also very satisfactory.

[3] THE LANCET, Jan. 23rd, 1904, p. 207.

Supposed causes.—If the exact causes of this outbreak of scurvy cannot be unequivocally determined something of importance at least may be gathered from a consideration of the circumstances attending and preceding its occurrence from facts observed by others and from the results of treatment. Most of the kaffirs who gravitated to Bloemfontein after the war had followed the fortunes of the British army for nearly three years previously, and during that time they had been served with the same rations as the British soldier —namely, preserved meat and vegetables. The food was good and consequently, in spite of many hardships, the kaffirs, who were on active service, remained healthy, while scurvy was not unknown among those located in refugee camps. After peace was declared, however, the conditions of service with the Government were reversed, the natives providing all their own food except the kiln-dried mealie which was issued as the Government ration.

Those who know the kaffir and his haphazard habits in regard to securing food will not readily infer that, in these circumstances, good meat was more than a precarious element in his daily diet. In any case these were the conditions, so far as ascertainable, under which the disease occurred in Bloemfontein, and it may be presumed that those cases found among natives not employed by the Government were in a measure contributed to by the conditions necessarily arising out of a state of war which cut them adrift from farms on which they were regularly employed and fed, and where the fresh South African grown mealie formed a more or less certain constituent of their daily fare. The use of the imported mealie has at different times been adduced in explanation of outbreaks of scurvy in the South African mines, and an outbreak in the Southern Bechuanaland Protectorate in 1903 followed upon the substitution of the American for the African grown mealie.

It may be legitimately inferred, however, from observations made by Dr. Donald M. Macrae, that the outbreak of scurvy in the prison of Gaberones, Bechuanaland, was contributed to by the exclusion of meat, except in the case of Europeans, from the prison dietary. Natives doing hard labour were fed on mealie meal thrice daily, but European prisoners were allowed one pound of fresh meat per diem in addition. Scurvy of a most intractable kind broke out among the natives, while the Europeans escaped the disease. The inclusion of fresh meat in the native dietary, however, has completely banished scurvy from the Gaberones prison. A casual examination and comparison made four years ago of the prison scale of rations in different parts of South Africa convinced the writer that no surprise ought to have been expressed at the existence of scurvy, occasional or otherwise, among native prisoners, except on the assumption that the average kaffir is superior to the common wants of nature. It may be presumed, however, that an improved dietary accounts for the absence in recent medical literature of any reference to prison scurvy in South Africa.

Finally, it has already been pointed out how the continued use of kiln-dried mealies in hospital, even with lime-juice and such fresh vegetables as were available, was followed by untoward results. And it has been remarked that the mortality in the native Military Hospital at Bloemfontein ceased shortly after fresh meat was added to the daily diet. Again, fresh meat, when used exclusively in the manner described in the case of the native boy referred to, was found to be a powerful antiscorbutic. So far, then, the evidence connecting the incidence of the disease with a deficiency of fresh vegetables is more or less direct, while that associating it with defective meat is less direct than inferential.

General remarks.—Although the explanations of scurvy hitherto given—from the etiological side—can at best be received only as graduated certainties, liable at any time to correction or revision, still the arguments advanced at different times in support of the prophylactic and curative remedies employed in the disease are based upon the practical experience of competent observers. When, in the domain of speculative or scientific thought, eminent men are divided in opinion they usually divide the truth between them. Whatever differences of opinion may exist in regard to the etiology of scurvy or the methods of treating the disease, it seems that one point has not been sufficiently emphasised on which all might well have agreed—namely, that in a disease which reduces the body to a condition of extreme debility the remedy which is best calculated to yield the maximum of energy in the minimum of time is that which ought in the first place to be applied. Specifics apart from this are valueless. The juice of fresh raw meat, owing to its stimulating and nutritive properties, is well suited to such a condition. And the same may be said of fresh milk, the albuminoid constituents of which supply the place of the rich animal food mentioned. Both are antiscorbutics, both supply energy, and both entail the minimum of strain upon the assimilative functions of the body.

It is a fact of clinical experience, supported by the authority of generations of observers, that the addition of fresh vegetables and lime-juice to an ordinary "general diet" cures the average case of scurvy. But since it has been recently observed that a certain constituent of what is called a "general diet" is itself a powerful antiscorbutic, doubt has arisen as to whether the virtues ascribed to the time-honoured specifics—fresh vegetables and lime-juice—have not often been largely reinforced by that component of the "general diet" to which specific qualities were not attributed in the past. It seems beyond doubt, however, that the elements necessary to maintain the equilibrium of bodily health belong to both fresh vegetables and animal food. Yet the facts of clinical experience have convinced the writer that the recent tendency to ascribe even the preponderance of merit in the treatment of scurvy to the use of fresh meat is not without considerable justification. In fresh raw meat or raw-meat juice the physician possesses a remedy which he may use even in severe cases of scurvy, in the invincible assurance that he will not be put to shame, but it is especially valuable in those cases which seem to linger on indefinitely under the ordinary methods of treatment.

It should not be forgotten, however, that the question as to the relative value of meat and vegetables in the treatment of scurvy is an old one, for this was a moot point among naval surgeons as early as 1797.[10] The eminent physician, Sir Thomas Watson,[11] used roast beef in the treatment of the disease and has spoken highly of its efficacy. And it may be gathered from the records of the early navigators that the Island of Juan Fernandez proved a paradise for their stricken crews, not merely on account of its richness in fresh fruits and vegetables but also because "it abounded in herds of wild goats," the flesh of which, as Dampier tells us, formed part of the dietary of his scorbutic sailors.

Scurvy is still met with in South Africa, notably in Johannesburg and its environs, and different opinions have prevailed as to its real nature. Some have spoken of it as associated with a form of beri-beri,[12] while others have regarded it as a new disease quite distinct from the classical type described in text-books. Quite recently Dr. N. MacVicar, of the Victoria Hospital, Lovedale, has in a careful and sensible article given his own impressions of the disease as found by him among the natives in his immediate vicinity and some of his observations, particularly those concerning pyrexia in scurvy, corroborate those which were made four years earlier in the military hospital at Bloemfontein.[1]

[12] Transvaal Medical Journal, June, 1906.

[13] South African Medical Record, April 25th, 1906, p. 1.

ROYAL PORTSMOUTH HOSPITAL.—At a meeting of the governors of this hospital held on June 19th a formal proposition authorising the sale of funded property to the amount of £4000 to meet the cost of a new out-patient department was about to be moved when the gratifying announcement was made that a donor who wished to remain anonymous would defray the entire cost of the new building. This splendid gift should stimulate all classes in Portsmouth and the neighbourhood to maintain the hospital in the highest efficiency and to promote its widest service.

false joint and the middle portion of the glenoid cavity, without disturbing the important origins of the biceps and triceps from the upper and lower borders of the rim. 3. At the operation an assistant could cause the deformity resulting from the dislocation to aid the surgeon; by means of the arm he could push the neck of the scapula towards the surgeon and hold it fixed whilst the glenoid cavity was being excavated. 4. The head of the humerus was replaced with its muscular insertions and its articular surface intact. It could then move freely in the excavated glenoid cavity. But it was not liable to become displaced again, for all the muscles were still attached yet had become somewhat shortened in the time which had elapsed after the accident. Hence passive and active movements could be begun early. If indeed the operation were to be adopted for a quite recent dislocation, whilst the rotators of the head were still stretched or perhaps partly torn, then it might be necessary to limit the movements of the shoulder until the muscles should have contracted up.—The PRESIDENT said that the value of the operation was in obviating the division of the important muscles round the shoulder-joint.—Mr. RUSHTON PARKER said that enough was not done in these cases to make surgeons acquainted with the amount of defect that might be tolerated without impairing the power of a working man to earn his living. He thought that the operation described by Mr. Spencer was deserving of recommendation.—Mr. T. H. KELLOCK gave the details of a similar case in which he had performed an operation like that described by Mr. Spencer, but he (Mr. Kellock) had used an anterior incision. He suggested that a posterior and an anterior incision would be the most satisfactory way of approaching the joint in these cases.—Mr. SPENCER replied.

Mr. ALBAN H. G. DORAN read a paper on a Cystic Tumour of the Suprarenal Body successfully removed by operation. He reviewed the records of 13 cases of cystic tumour of the suprarenal body, large enough to be of clinical and surgical interest, including one in his own practice of a woman aged 62 years who had been subject for ten years to attacks of pain after food, and recently to sharp pains referred to a firm oval tumour in the left *hypochondrium*. It was half hidden under the ribs but could be pushed downwards below them. There was resonance on percussion over part of its anterior surface. Diagnosis was uncertain. He operated, making the abdominal wound along the outer border of the left rectus. The peritoneum was incised externally to the descending colon and the tumour was enucleated with ease. Some large vessels running into its upper and inner part required ligature. The left kidney was seen lying internally to the tumour and mainly below it. No drainage was employed. The tumour was a thick-walled unilocular cyst, containing half a pint of bloody fluid. Much adrenal tissue was detected in its walls. It was an instance of the struma suprarenalis cystica hæmorrhagica of Henschen. Several other cysts of this class were included in the series, to which was added a doubtful case recorded by Lockwood. The minority were adenomatous or lymphomatous cysts. A history of injury existed in two out of the 13 cases; attacks of local pain were the rule; bronzing of the skin was noted in one case only (McCosh) and it disappeared after removal of the tumour. Incision and drainage had proved most unsatisfactory; the wall of a blood cyst was soft and in one instance tore itself away when sutured to the abdominal wound, with a fatal result. In another case the patient died, and it was afterwards found that the cyst could easily have been enucleated. This incomplete operation was adopted in a third case because the cyst was believed to be pancreatic so its base was not removed. The patient recovered. Complete removal of the cyst was the proper surgical treatment. Recovery followed respectively in Pawlik's, McCosh's, and his own (Mr. Doran's) cases, as well as in Lockwood's case, where the nature of the cyst was doubtful. The proximity of the aorta or vena cava should always be borne in mind. Six of the cases were mainly of clinical interest, not having been subjected to operation.—Mr. C. B. LOCKWOOD said that he had in 1898 exhibited a retroperitoneal cyst[3] supposed to have originated in remains of the Wolffian body and he had operated in two additional cases in which both the patients were young women, recovery following the operation in each case. Both the cysts were in the left side. One was the usual type of cyst, full of clear fluid and freely moveable. The other cyst was attached to the lower end of the left kidney and at its attachment some solid growth was found which proved to be adrenal tissue. Mr. Lockwood considered this case to supply a very important link in the chain of evidence which had led him to attribute the origin of these retroperitoneal cysts to remains of the Wolffian body which, as was well known, gave origin to the adrenal body and adrenal remains. These retroperitoneal cysts had fairly constant clinical characters. The patients were nearly always females. The tumour was on the left side, it was freely moveable, and was usually thought to be a moveable kidney. It caused continual pain and discomfort. In the four cases of which Mr. Lockwood had had experience the cysts were safely removed by incision into the abdomen through the outer edge of the left rectus abdominis, the cysts being exposed by dividing the descending meso-colon. In the case of the cyst attached to the kidney the kidney substance was incised and brought together with catgut.—Mr. DORAN replied.

Mr. RUSHTON PARKER read a paper on a case of very severe Compound Fracture of the Arm which he illustrated by photographs and lantern slides. The points to which he desired to draw attention were the slinging of the arm to the neck and the flexion of the elbow to a more or less acute angle. In a fracture of the lower fourth of the humerus on account of the invariable tendency to adduction of the condyles under the weight of the elbow a twist imparted to a metal splint hollowed to fit the limb effectually maintained the lower smaller fragment in line with the upper while controlling both.

Mr. PARKER also read a paper on Two Cases of Ununited Fracture treated by Planting Small Fragments of Bone between the Ends.

OPHTHALMOLOGICAL SOCIETY.

An Epidemic of Contagious Conjunctivitis Due to the Pneumococcus.—Hereditary Eye Disease.—Secondary Xerosis.—Lower Corneal Plaques.—Exhibition of Cases and Card Specimens.

A MEETING of this society was held on June 11th, Mr. R. MARCUS GUNN, the President, being in the chair.

Mr. P. E. H. ADAMS read a paper on an Epidemic of Contagious Conjunctivitis due to the Pneumococcus. He said that the epidemic occurred in the spring in a small school of 37 boys, 21 of whom were attacked. The eldest boy affected was 14 years of age, the youngest being nearly ten years old. All the smears taken except one showed numerous Gram-positive diplococci. Most of them were typically flame-shaped pneumococci with capsules, though a few of them were rounder in shape and in some the capsules were not evident. This agreed with the description given by Schmidt[1] of smears taken from cases of pneumococccal conjunctivitis. On blood agar the colonies were typical slow-growing pneumococci and there was no growth on agar. Only three of the cases were at all acute, most of them being subacute or quite mild. Four cases of relapse were reported. The condition found on examination was fairly constant—general congestion of the lower palpebral conjunctiva, with slight injection of the ocular conjunctiva, and in the acute cases a thin line of muco-pus in the folds of the conjunctiva of the lower lid. The upper lid showed slight enlargement of follicles at the angles, and a row of minute follicles along the everted edge. The whole epidemic lasted about five weeks and spread in spite of isolation. It agreed in almost every respect with previously reported outbreaks, the chief difference being the generally mild nature of the cases.

Mr. E. NETTLESHIP read notes of three cases of Hereditary Eye Diseases. Case 1 was that of a husband and wife who had senile cataract at an advanced age, and both were operated on with success. They had ten children, seven of whom had cataract in various degrees, two of these having had them "matured" and operated upon at a much earlier age than in their parents. There were also slight lenticular changes in the grandchildren of the original couple. The second family showed the occurrence of "Coppock" or discoid cataract, and lamellar cataracts of various sizes, and likewise of retinitis pigmentosa. Among about 250 persons Mr. Nettleship had been able to trace, belonging to the family, 32 with family cataract and 15 with retinitis pigmentosa. The sex incidence and mode of descent were shown to be different for the cataract and retinal disease shoulder with very limited mobility. After prolonged passive movement and massage the patient would generally not be able to raise his arm above the level of the shoulder. Subcutaneous division of bands and osteotomy of the neck of the humerus had not obtained any vogue. The method of obtaining reduction through a posterior intermuscular incision by excavating the glenoid cavity suggested itself to Mr. Spencer because it seemed an adaptation to the shoulder of the procedure previously employed at the hip. For a traumatic dorsal dislocation of the hip of five months' standing in a boy aged seven years he had made an anterior incision between muscles, and without injuring any important structure excised the obstructing capsule and the dense fibrous tissue filling the acetabulum. After making a well-marked cup the unaltered head of the bone was returned into place by manipulation without using any force. He afterwards showed the boy at a meeting of the Clinical Society of London with a good return of movement.[4] He could not find that he had been anticipated in the description of the operation which he had adopted on the shoulder, nor in putting forward the considerations which seemed to him to support the method. As to a posterior incision to expose the shoulder-joint Kocher in his "Operative Surgery" described cutting through the acromion and infraspinatus. He had followed the recommendation in the case of tuberculous disease in a child in which the glenoid cavity was the chief part affected and a caseous abscess was pointing behind. But that was a quite different operation. Indeed, all writers contemplated old dislocations of the shoulder from the front. The only illustration of a dissection from behind which he had met with was contained in a tract by Bonn in the library of the society. It was a drawing from a dissected post-mortem specimen and it showed in particular the mass of thickened capsule with calcareous plates resulting from the injury. Moreover, in old shoulder dislocations placed in museums they had usually been dissected from the front. He showed an exception to that from the Royal College of Surgeons Museum. It was a post-mortem specimen dissected by Flower and it exhibited the relations of the muscles, but much of the thickened capsule had been cut away as well as part of the deltoid, the infraspinatus, and the teres minor. The relation of the long head of the biceps and that of the triceps to the dislocation was the chief point to which he would draw attention in the specimen. The occasion for the employment of the operation was as follows. A weakly man, aged 53 years, had had ten years before a cerebral vascular lesion causing right hemiplegia and aphasia. From that he had so far recovered but his right side remained weak, and his speech was difficult to understand, though that was partly due to his being edentulous. In August, 1907, he was walking on the pavement when he slipped off the curb and fell into the gutter, hurting his left shoulder. He went at once to a medical man who, so he said, told him that there was nothing wrong with the shoulder. Three weeks later, on the advice of a friend, he attended the out-patient department of a general hospital; then he was anæsthetised and an attempt at reduction was made. He was then admitted to the hospital ward and two further attempts at reduction were tried, both under an anæsthetic. He was afterwards given to understand that nothing more could be done for him and he left the hospital. Two months later he went to Dr. S. G. Tippett of Staines who at once sent him into the Westminster Hospital under him (Mr. Spencer). His left arm could hardly be moved at all from the side on account of a subcoracoid dislocation by which the head of the humerus was firmly fixed to the scapula. There was extensive eczema in the axilla and around owing to the arm being kept to the side. The dislocation on the left side, along with the hemiparesis on the right, rendered him quite helpless. Thus an operation to free the left shoulder was particularly indicated, whatever objection might be made to it on account of the weakness of the patient and the probable state of his cerebral vessels. He operated on Nov. 13th, 1907, three and a half months from the time of the accident, after especial care had been devoted to preparing the armpit, owing to the eczema which had followed the adduction of the arm. The patient was laid on his right side and he (Mr. Spencer) stood behind him on the left; the dresser held the left arm as much raised as he could so that the posterior surface of the arm looked upwards and forwards and at the same time pushed the humerus towards the operator. This was a primary feature of the method; the glenoid cavity and neck of the scapula could be thus pushed towards the incision and held there fixed by making use of the head of the humerus in its displaced position underneath the coracoid process. A semilunar skin flap was turned upwards over the acromion by making a curved incision which commenced over the middle of the spine of the scapula and ended over the posterior fold of the axilla. Then the upper border of the latissimus dorsi was freed, retracted downwards, and the posterior border of the deltoid was retracted upwards. The next step was to raise by means of a raspatory the teres minor and infraspinatus from their origin near their tendons so as to explore the axillary border and a small triangular area of the dorsum and neck of the scapula. That led to a good view of the origin of the long head of the triceps from the lower edge of the glenoid cavity and the axillary border of the scapula. He then began to cut away piecemeal a tough mass of tissue representing the posterior part of the capsule and to chip away the posterior rim of the glenoid cavity until he had reached the origin of the long head of the biceps from the upper margin. He had then the long head of the triceps below and the long head of the biceps above, both well defined at their origin but uninjured. Between these two tendons was a mass of fibrous tissue and fat representing the capsule, and remains of blood clot, some of which had become altered into melon-seed bodies, in the former joint cavity. No actual joint cavity remained, but a section under the microscope of a piece which had been cut away showed synovial membrane and greatly thickened subsynovial tissue. The rest of the thickened capsule was later excised in small bits, progressively with the removal of bone chips from the middle of the glenoid cavity, until the anterior rim which had come to form the posterior margin of the false joint below the coracoid process had been removed. When that was done the head of the humerus was exposed. Thus a cup-shaped cavity had been excavated between the origin of the biceps above and the triceps below and all the altered capsule had been cut away. A manipulation of the humerus by Kocher's method then caused the head to be reduced into the excavation. This manipulation without using force had been tried before but it was only after the complete removal of the anterior rim of the glenoid cavity, including the posterior border of the false joint, that reduction readily occurred. That a false joint had formed was further shown by the escape from it of synovial fluid whilst none was found at the site of the true joint. After reduction the head of the bone could be well inspected: its cartilaginous surface was unaltered; its muscular attachments were uninjured. When extension was made on the arm the head of the bone was only pulled downwards just enough to allow of the fingers being inserted between the head of the acromion. When extension was relaxed the head came into contact with the acromion. That was due to muscles and ligaments having shortened. The head could not be pushed further back than the excavated glenoid cavity on account of the tenseness of the subscapularis. In the excavated cavity the head rotated easily and the arm could readily be carried into the vertical position. On removing the retractors the muscles returned into place and as the head of the bone now filled the deepest part no wound cavity remained, so the skin was sutured without a drain. He had expected to meet with the dorsalis scapular artery, but he did not cut far enough down the axillary border to wound it. The whole plan of the operation had kept him far away from the circumflex nerve and of course from the large axillary vessels and nerves. The wound healed well; before the sutures were removed the arm could be readily rotated. As soon as there was firm union massage, passive movement, and electrical excitation were adopted. The arm could be raised easily to the vertical and the patient slowly regained the use of the limb in a way which was quite satisfactory considering his general debility. That method of treating old shoulder dislocations appeared to have the following advantages:—1. The joint was exposed without dividing any important structure and the muscles which had been drawn aside fell back into place, so that no wound cavity was left in which blood clot could collect nor was drainage required. 2. Through the incision could be removed the impediments to reduction, viz., the altered joint capsule, and the bone *forming* the posterior rim of the further possibility that the coagulability of the blood might be altered by the action of the trophoblast which seemed to possess the power of extending along vessel walls without producing clotting. The complete embryo measured 1·9 millimetres by 0·87 millimetre by 0·64 millimetre; these measurements corresponded with those ascribed to embryos between the second and third weeks.—Sir A. R. Simpson, Dr. W. Fordyce, Dr. A. H. F. Barbour, Dr. F. W. N. Haultain, Dr. J. Haig Ferguson, and the President discussed the paper, and Mr. Wade replied.

UNITED SERVICES MEDICAL SOCIETY.—A meeting of the above society was held on June 11th, Inspector-General Sir Herbert M. Ellis, K.C.B., R.N., the President, being in the chair.—Lieutenant-Colonel H. E. Deane, R.A.M.C. (retired), read a paper entitled "A Plea for a More Detailed Study of the Soldier's Heart," and presented each member attending with a copy of a series of respiratory-pulse curves on which the paper was based. Having been obtained from soldiers, professional gymnasts, acrobats, and dancers, these were analysed, attention being given to the phenomena of pulsus paradoxus, extra systoles, and the results of strain. A diagram—taken by means of an ortho-radiographic machine—of the heart of a soldier who was holding his breath was exhibited and it showed a marked diminution of all the diameters of the heart. Reference was next made to cases of disordered action of the heart in soldiers. It was asked whether it was quite certain that the equipment had nothing to do with the subject. Investigation as to the circumstances in which the men broke down, a graphic record of the cardiac conditions, and a detailed examination of men after marching or after a field day were advocated. The instruments by which the tracings were obtained by Lieutenant-Colonel Deane were exhibited.—In the discussion which followed it was generally agreed that too much significance had hitherto been attached to the occurrence of extra systoles and it was stated that candidates for life insurance had been rejected or charged extra premiums and men invalided from the Services unnecessarily on their account. An example was given of a man being found doing heavy work as a luggage porter a few years after he had been invalided from the Marines. Seamen of the Royal Navy were not found to be specially subject to heart trouble but the Marines, whose conditions of life were similar to those of the soldier, suffered. It was stated that in soldiers it was not uncommon to find post mortem a certain amount of general hypertrophy of the heart.—Dr. Mackenzie, Colonel Beattie, R.A.M.C. (retired), Lieutenant-Colonel W. B. Leishman, R.A.M.C., and the President were among the speakers.—In his replies Lieutenant-Colonel Deane suggested clothing and the hustling to which the soldier is subjected as elements in the causation of the condition.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on June 5th, Mr. Richard Lake, the President, being in the chair.—Dr. Andrew Elliot opened a discussion on the Causes of Unconsciousness by a paper dealing with the causes of insensibility, and secondly with the general methods of investigation which would be found of use. He emphasised the necessity of a clear idea of the various possible causes of unconsciousness in order that none might be overlooked and suggested a tabulation of the possibilities based on a *memoria technica*. Referring to the examination of an individual case, he urged a systematic method of procedure by a scrutiny of the following points in succession: (1) the history, if obtainable, of the case; (2) the general condition of the patient and the depth of the coma present; (3) signs of injury, especially cranial fracture; (4) any peculiarity in the breath; (5) the condition of the tongue and mouth; (6) the pulse, temperature, and respiration; (7) local paralyses or rigidities; (8) the general sensation; (9) the reflexes; (10) the eyes (muscles, pupils, cornea, and fundus); (11) the urine; (12) the stomach contents; and lastly, if necessary, an examination of the cerebro-spinal fluid withdrawn by lumbar puncture.—Dr. A. E. Russell continued the discussion and commented on the unconsciousness of epilepsy, pointing out that in some cases convulsions might be so slight as to escape notice or even be absent. In some cases of hysterical attacks the diagnosis from epilepsy was not easy, especially in view of the frequent complete absence of knowledge by the patient of what had occurred during the attack; the possibility of some of these attacks being really the sequel of unrecognised petit-mal had also to be borne in mind. As regards apoplexy, in children embolism, and in young adults syphilitic endarteritis had to be considered, whilst in older adults thrombosis from cerebral arterio-sclerosis and cerebral hæmorrhage were the chief factors. Thrombosis was more common than was usually suspected. The chief points in coming to a diagnosis were: the presence of premonitory slight and transient attacks; the frequent mildness of onset and the presence of a low-pressure pulse and dilated heart in cerebral thrombosis, as compared with the more violent onset, the deeper and more prolonged unconsciousness and the high blood pressure and hypertrophied heart, so commonly found in cases of cerebral hæmorrhage. The importance of accuracy of diagnosis was obvious in view of the different methods of treatment required in the two classes. The condition of uræmia was also considered. Catalepsy was a rare phenomenon but did occasionally occur. The unconsciousness met with in men working in deep wells and the holds of ships was also referred to. Dr. J. S. Haldane had shown that this was due to absorption of oxygen from the air leaving an atmosphere composed in the main of nitrogen. The danger of this was that the patient did not as a rule recognise his danger owing to the absence of marked dyspnœa or discomfort, and unconsciousness occurred very suddenly.

Reviews and Notices of Books.

Nothnagel's Practice: Diseases of the Heart. By Professor TH. VON JÜRGENSEN, Professor L. VON SCHRÖTTER, and Professor L. KREHL. Edited with additions by GEORGE DOCK, M.D., Professor of Theory and Practice of Medicine and Clinical Medicine, University of Michigan, Ann Arbor. Authorised translation from the German under the editorial supervision of ALFRED STENGEL, M.D., Professor of Clinical Medicine in the University of Pennsylvania. London and Philadelphia: W. B. Saunders Company. 1908. Pp. 848. Price 21s.

THIS work forms one volume of Nothnagel's "Encyclopædia of Practical Medicine" which is now being translated into English. The editor, Dr. Dock, remarks in his preface that although several excellent works upon diseases of the heart have appeared within the last quarter of a century in Germany yet none of them have been translated into English. This is especially strange when it is considered that many important contributions have been made by observers in that country to the normal and pathological anatomy of the heart and circulatory system, the methods of diagnosis, the pharmacology of cardiac remedies, and the application of non-medicinal measures to the treatment of patients suffering from affections of the heart. The volume now before us is a large one, and in it we find, to quote Dr. Dock's words, "the sound learning and wide clinical experience of Professors von Jürgensen and von Schrötter and the deep and broad training in anatomy, physiology, and pathology, as well as the excellent clinical observations of Professor Krehl."

Matters of interest brought out since the original was published have been added in brackets. These include American and English contributions, so that by this means the work is brought well into line with recent observations, which naturally increases the value of the book as a work of reference.

The first section of the book is by Professor Jürgensen and deals with Insufficiency (Weakness) of the Heart. An interesting account is given of the symptomatology of this affection, in the course of which some remarks are made on the development of dropsy which are well worthy of attention. The observations of von Lesser, Grawitz, and others are carefully considered and criticised. There is no doubt that one of the chief conditions for the production of dropsy is slowing of the circulation. Wherever the slowing is greatest œdema develops most early. On the other hand, there are other factors at work which are not so well understood. It has been shown that cardiac insufficiency is attended more often by dilution than by concentration of the whole blood. It is probable respectively. The third case was that of a family containing colour-blind individuals. Mr. Nettleship had examined all the available members, and of 33 males 14 were found to be colour-blind, and of 36 females only one was affected, and she slightly. There were 40 others in the pedigree who were either dead or inaccessible.

Lieutenant-Colonel H. HERBERT, I.M.S. (retired), read a note on Secondary (Parenchymatous) Xerosis. He drew attention to the part played by pannus in the development of xerosis after trachoma, and pointed out that old pannus rendered the corneal surface insensitive. Hence with both corneæ covered with pannus the blinking movements of the lids tended to be imperfect, and thus to lead to exposure of the globe. This appeared to be an important factor in the dryness which followed, for in such cases xerosis of the cornea and conjunctiva was often very marked when the cicatricial degeneration of the conjunctiva was much less advanced than in other old trachomatous cases in which the eyes remained moist and the corneæ clear. The exposure of the cornea rendered it more opaque and insensitive, so that the blinking movements might amount to only very infrequent and slight twitches of the lids. Similarly inactive lids were seen in India in a few cases of severe primary (epithelial) xerosis. In these cases the exposed cornea became not only opaque but pigmented, like the degenerate conjunctiva. Here the primarily defective reflex action of the lids seemed to be attributable to malnutrition only. Another factor in the production of cicatricial xerosis was the reduced transudation of fluid from the palpebral conjunctiva. If the upper lid were everted in any case of ordinary acute conjunctivitis a free flow of watery fluid was readily demonstrable from the exposed conjunctiva. But a similar flow was not obtainable from a cirrhosed or cicatricial conjunctiva, however much inflammation might be present.

Lieutenant-Colonel HERBERT also read a paper on Lower Corneal Plaques. These, he said, were slightly raised, feebly vascular, grey patches with rough surfaces, close to the lower margin of the cornea. Their opacity varied with their thickness. They were often of curious shapes and were mostly multiple and binocular. They were not very uncommon in India and appeared to be due to slightly defective closure of the lids, together with more or less chronic conjunctivitis, trachomatous or otherwise.

Mr. J. PRIESTLEY SMITH showed a small instrument, consisting of a series of lenses aranged in a frame, for use with the shadow test. The feature of the apparatus was the close packing of the lenses, about 16 of them being contained in a linear foot, which enabled very rapid examinations to be made.

Mr. LESLIE J. PATON showed a case with Connective Tissue in front of the Optic Disc.

Dr. F. W. EDRIDGE-GREEN exhibited an improved Lantern for Testing Colour-perception. There was an arrangement consisting of three slides in a vertical column, each slide being fitted with variously coloured glasses which could be brought opposite an aperture with an iris diaphragm.

Mr. J. H. TOMLINSON showed a Nernst Lamp Projecting Lantern.

Mr. SYDNEY STEPHENSON showed a patient with a curious Congenital Anomaly of the Iris.

Mr. G. W. ROLL showed a patient with Sky-blue Sclerotics, and also one with Double Papillitis.

Mr. A. O. HUDSON showed a case of Thiersch Grafting.

Mr. G. COATS showed a case of Exudation in the Retina.

EDINBURGH OBSTETRICAL SOCIETY.—A meeting of this society was held on June 10th, Professor W. Stephenson, the President, being in the chair.—Sir A. R. Simpson gave an account of his visit to the Gynæcological and Medical Societies of Japan and exhibited albums presented to him by the members.—Mr. Henry Wade and Dr. B. P. Watson made a communication on the Anatomy and Histology of an Early Tubal Gestation, with lantern demonstration. The gestation was one probably between the second and third week, and a complete picture of the case was obtained as over 1900 sections were made of the affected part of the tube and the other pelvic organs were obtained in a fresh condition at the necropsy. The patient, aged 30 years, had been subject to gastric disorder. On the night prior to her death she had sent for her medical attendant for slight abdominal pain and diarrhœa. She informed him that she had had a normal menstrual period two or three weeks previously. On the next afternoon she became rapidly worse and died before arrangements could be made for operation. At the post-mortem examination the abdomen contained a large amount of dark fluid blood with large clots in the pelvis. At the uterine end of the right Fallopian tube there was an almond-shaped swelling measuring a little over one centimetre in its long axis and of a dark prune-juice colour. It was covered with glistening peritoneum except over a small area about the middle, which was of a lighter colour, and the peritoneum was more opaque and lustreless, and in its centre a minute perforation was present from which blood oozed on gentle pressure. The right ovary showed no abnormality, but the left was enlarged and cystic, and there was a small fibroma growing from the junction of the left ovary and ovarian ligament. The uterus was enlarged, soft, and somewhat boggy to the touch; on section its cavity was lined by a thick decidua. The swelling on the tube was found to be situated in the isthmus and bulged more towards the broad ligament attachment than to the upper surface. The swelling measured 1·3 centimetre in length, 1 centimetre in breadth, and 1 centimetre in thickness. The rest of the tube, including the fimbriated end, appeared quite normal. Transverse sections of the tube on the uterine side showed no abnormality in the fibrous and muscular tissue. The villous processes of the mucosa were more numerous and complicated than usual and joined across the lumen to produce a net-like appearance on section, and the epithelium on these processes was swollen and in many places desquamated. The capillaries were engorged with proliferation of the endothelial lining and accumulation round the vessels of cells mainly of the small lymphocyte type. No diverticulum of the tube was evident. If one or two sections had been examined it would have appeared that there was a double channel in the tube, but on tracing this through other sections it was found to be due to projection of connective tissue proliferation into the tube. Similar appearances would be produced by folding and twisting a rubber tube. There was evidence of recent catarrh in both tubes but it was slight in the non-pregnant tube and the appearances might be accounted for by a post-mortem change. On the right side—the pregnant side—it was distinctly present, especially on the uterine side. Sections through the middle of the gestation sac showed the ovum with its villi filling up the whole interior of the tube and no lumen was visible. At either extremity of the sac the lumen was intact and the ovum was seen extending not along the lumen but in the muscular coat of the tube; that is, the ovum was growing on the tube wall; probably it had previously become imbedded there. The villi of the ovum were seen to penetrate and to destroy by the advancing trophoblast the muscular wall of the periphery of the tube in different parts; this was greatest near to the point of rupture. There was a well-marked decidual lining in the uterine cavity, consisting of compact and spongy layers. The only other situation in which true decidual formation was found was in the villous processes of the mucous membrane of the pregnant tube on the uterine side of the gestation sac, and of the interstitial portion; but no membrane, only a cellular reaction. It was entirely absent in the tube of the other side, in the ovaries, and in the connective tissue of the broad ligament. In sections through the middle of the gestation sac the chorionic vesicle, covered with epiblast and containing the embryo in its amnion, was well seen. There was a reaction on the part of the maternal tissues by hyperæmia and œdema, with blood extravasation and fibrin formation; that was for protection of the maternal tissues against the invasion of the advancing trophoblast. In one place the wall of a blood sinus had been destroyed by the trophoblast causing a large hæmorrhage into the ovum bed in the thinned out wall of the tube. This had weakened the tube and possibly as the result of muscular contraction of the remainder of the tube wall, the peritoneal coat of the tube had ruptured and intraperitoneal hæmorrhage had resulted. According to the view of Mr. Wade and Dr. Watson the decidua must be looked upon not simply as a suitable bed in which the ovum can bury itself but as a barrier laid down to prevent the too great destructive action of the trophoblast. The absence of any distinct decidual membrane in the tube wall would on this theory readily explain the frequency of tubal rupture. The rupture was very small and opened into a comparatively small vessel. Spontaneous arrest of the bleeding might have been prevented by the failure of the weakened muscular coat to contract, and there was the bleeding to stimulation was an excessive one. It must be admitted that greater care is now being exercised by medical practitioners in prescribing alcohol for their patients, and there are few who would now cavil at the author's plea that the practitioner in ordering alcohol should regard it as a drug and not as a beverage, and should exercise an equal care in its administration with that taken in regard to other drugs. Doubtless in the past the indiscriminate ordering of stimulants to invalids may have led to subsequent intemperance. To recognise that this is a possibility is to admit the necessity for care in this respect.

The remainder of the book is devoted to a review of the treatment of inebriety. The various "patent cures" are discussed and the commercial aspects of most of them are exposed. The author points out the unsatisfactory nature of the evidence on which the reputed cures are based, the absence of data as to the duration of the cures, and the probability that most of the rapidly successful cases are examples of dipsomania or periodic intemperance, in which after the bout is over remorse leads to a temporary improvement. He also deprecates the use of powerful and poisonous drugs in such treatments. A chapter on the inebriates homes and reformatories constitutes an eloquent plea for the support of these institutions and for more prolonged treatment of those admitted to them. Some statistics prepared by Dr. R. W. Branthwaite, the inspector under the Inebriates Act, are quoted, showing the large proportion of those admitted to such institutions who show evidence of mental defects. It is admitted that in some of these the mental deficiency existed before the alcoholism supervened. The author also expresses the hope that more careful methods of selection will eventually prevail; for, as he expresses it, "imbeciles, epileptics, monomaniacs, and idiots, though alcohol made, are as much out of place in a home for inebriates as they are in the prison cell, to which they are committed again and again." In the last chapter the care of the individual inebriate at home under the supervision of the medical practitioner is outlined and the view is expressed that no sane inebriate need be regarded as incurable.

The book is well written in simple but forcible style. It constitutes an earnest endeavour to promote national temperance and to deal with the problem of inebriety.

How to Nurse the Patient: a Handbook on Nursing for the Use of those in Charge of the Sick. Edited by J. COWAN WILSON, M.B., C.M. Glasg., D.P.H. Camb. Glasgow and Edinburgh: William Hodge and Co. 1908. Pp. 324. Price 3*s.* 6*d.*

THIS handbook on nursing is the combined work of medical men and trained nurses. The training of a nurse at the present time is carried out with method and completeness. Not only are the technical details carefully explained and demonstrated but the probationer is encouraged to take an intelligent interest in her work by means of lectures delivered by medical men on elementary anatomy and physiology and on simple medical and surgical facts which may help her in times of emergency. At the same time, it is emphatically insisted on that these lectures are not intended to enable the nurse to usurp the place of the medical attendant in any circumstances.

These principles are fairly well carried out in the volume now before us. The plan followed throughout the book is to deal simply with methods of nursing, leaving the treatment of the disease to the practitioner in attendance. Description and treatment of the various diseases have only been touched on in so far as they are of practical use to the nurse. At the same time, special attention has been given to symptoms which might readily occur in the absence of the medical attendant and which are likely to cause suffering and alarm. Although in most cases the advice given is perfectly trustworthy, yet in some instances directions are given which we should like to see altered in future editions. For instance, under the head of "Hæmoptysis," the emergency treatment is antiquated and of a nature which should not be left to the discretion of a nurse. A subcutaneous injection of 1-100th of a grain of ergotinine is recommended. This drug is now not used in cases of hæmoptysis by the best authorities. Ergot raises the blood tension, which is precisely the reverse of what is required to enable arrest of hæmorrhage to take place. Further, it would be a doubtful plan to allow a nurse to administer "a full dose of solution of morphine or laudanum" on her own responsibility. On the other hand, under the heading of "Pain," valuable information is given as to the significance of the chief varieties of pain and the simple methods which may be adopted for the temporary relief of this symptom until medical assistance arrives. The use of opium is indicated but information is given as to certain conditions in which it should never be used, and in regard to the employment of injections of morphine the proper words are added, "with the permission of the medical attendant." We agree with the remark in the preface, "It is of more importance that the nurse should be able to relieve pain or sickness, and manage insomnia or a high temperature, &c., than make a correct diagnosis." Nevertheless, there are distinct limits to the methods which a nurse may employ on her own initiative. We are therefore glad to see under the heading of "Sleep and Insomnia" the warning, "The nurse should avoid the use of hypnotics to procure sleep." The general directions given for the management of surgical and medical cases are good and trustworthy and a nurse will obtain much knowledge and useful hints by a study of this book.

These are very many advertisements bound up with this work with regard to which the following explanation is given in the preface: "The object of the book being, at least in part, to assist the Cottage Hospital Fund, affords an explanation for the numerous advertisements which appear." Further we read: "...... the proceeds of the sale of the book should go to the building fund of Blantyre Cottage Hospital." Nevertheless, although the object in view is most praiseworthy, a more careful selection of the advertisements would have been desirable. There are at least two which could with advantage be eliminated.

We may add that the book contains not only directions as to nursing medical and surgical cases as ordinarily understood, but also the duties of the nurse when in charge of infectious and obstetric cases, and also some useful hints on the feeding of infants are included.

LIBRARY TABLE.

The Anæsthetic Technique for Operations on the Nose and Throat. By A. DE PRENDERVILLE, Senior Anæsthetist to the London Throat Hospital, &c. With 19 figures. London: H. J. Glashier. 1906. Pp. 87. Price 3*s.* 6*d.*—Mr. de Prenderville emphasises the two following points in preparing a patient for an operation on the throat and nose: a preliminary nasal toilet and a preliminary cleansing of the mouth and teeth, with the object of avoiding an undue flow of mucus early in the operation and of reducing the risk of sepsis and of vomiting. In selecting the anæsthetic the one to be chosen is as free as can be from danger and from causing local congestion. In discussing the posture of the patient, the administrator is shown how to place *himself* in case he should be required to act also as sole assistant; he is also advised when about to anæsthetise with nitrous oxide gas if a gag is employed instead of a prop—a procedure saving several seconds—that the gag should be opened wide to minimise the risk of injuring teeth when the masseters are rigid. Nitrous oxide is also said to be contra-indicated for children under that there is some change in the distribution of the red blood corpuscles and that they are more numerous wherever there is retardation in the blood current or stasis. From this it should follow that, if there is no increased formation of red blood corpuscles, the number must be less than normal in those parts of the body which are not affected by the stasis. Further, it would follow that the quantity of hæmoglobin in the circulation—that is, the quantity of oxygen supplied to the tissues—must decrease in proportion as the stasis, the temporary exclusion of red corpuscles from the pulmonary circulation, increases. Serious injury to the functional power of all the tissues of the body would necessarily follow. Following on these and similar arguments Professor Jürgensen arrives at the conclusion that the details of the processes producing dropsy are not known. Negatively it may be said that the phenomenon is due to more than a mere alteration of pressure or nutritional change in the vessel wall, making the latter more permeable for the blood. Again, the peculiar properties of the capillary walls come into play; their activity is dependent upon the vital activity and hence on the nutrition of the individual cells of which they are composed. The manner, as well as the degree, in which these are injured probably varies at times, but at present, as before said, very little is known about the matter.

The second section of the work (also written by Professor Jürgensen) is concerned with a description of Endocarditis. The etiology, morbid anatomy, symptoms, diagnosis, prognosis, and treatment are discussed at length. The author maintains that endocarditis is always part of a general infection the severity of which determines the clinical course. He considers that the endocardium is never affected alone but that the entire heart takes part in the morbid process. The work of the heart may be interfered with by insufficient closure of the diseased valves, or as the result of the narrowness of their orifices, and also in consequence of the loss of power in the heart muscle, following lesions which affect this structure directly and which arise either from inflammatory or degenerative processes. Professor Jürgensen does not think that it is correct to regard endocarditis as a separate entity but believes that "pancarditis" will be the diagnosis of the future. Professor Jürgensen is also responsible for the third section on Valvular Disease, which is considered with the same thoroughness of detail as the preceding sections.

The section on Diseases of the Myocardium and Nervous Diseases of the Heart is written by Professor L. Krehl of Greifswald. The remarks on the "general principles to be observed in the treatment of heart patients" are particularly interesting. He points out that all therapeutic directions must be adapted in every respect to the patient's individual circumstances and must take in every detail of his mode of life. A good physician, after carefully diagnosing the disease in a given case, adopts a line of action appropriate to the patient's circumstances and personality. To do so the entire body and all its various functions must be taken into consideration. It is only by proceeding on these lines that satisfactory results can be arrived at. Professor Krehl's remarks on "cardiac fear and cardiac pain" are also worthy of note. It is well to remember that apprehensiveness and irritability are characteristic symptoms of disordered cardiac action and may be present when such symptoms as dyspnœa are absent. Fear is very frequent not only in sclerosis of the coronary arteries but also in myocarditis and the various other forms of muscular affections of the heart.

The last section in the book, that on Diseases of the Pericardium, is by the late Professor Schrötter of Vienna. In discussing the treatment of pericarditis due attention is paid to the operation of paracentesis. The author considers that the indications for such a procedure are: (1) when a large exudate does not show any tendency to absorption after a prolonged observation and after due trial of the means usually employed, and when the patient is more and more markedly affected by the disease; and (2) the vital indication, when the patient is threatened with death as the result of severe dyspnœa. Professor Schrötter points out that the results hitherto obtained cannot be said to be uniform, and it is perfectly natural that they should differ according to the presence of one or another primary disease responsible for the endocarditis.

We have formed a high opinion of the work as a whole. The forms of treatment recommended are not always those generally adopted in this country. For instance, we do not consider that sufficient importance is attached to the use of vaso-dilators in cases of cardiac insufficiency in order to lessen the peripheral resistance which the heart has to overcome. But those portions of the various sections dealing with the etiology and symptomatology of the various affections are most thorough in detail and scientific discussion. Our readers will find the diseases of the heart considered in a manner which is largely new to English readers, and a vast amount of information may be gathered by a study of the observations of the three authors who have recorded their experiences and conclusions. As a work of reference it will prove of great value and we cordially recommend it to our readers.

Sidelights on Alcohol and its Action on the Human Organism. By "MEDICUS ABSTINENS." With illustrations. London: Church of England Temperance Society. 1907. Pp. vi.–189. *Price* 2*s.* 6*d.* net.

THERE are few questions which have been more obscured by the wiles of the special pleader and polemic than those involved in the use and abuse of alcohol. That indulgence in intoxicating beverages even to a degree short of the conditions of intemperance and inebriety is calculated to bring about morbid changes in the human body and to lead to mental and physical deterioration is a fact which is only too patent to every practitioner of medicine. At the same time the bigoted attitude assumed and the exaggerated statements made in the past by some of the extreme partisans or abolitionists have tended to alienate the sympathies of many earnest people who, believing that alcohol has its uses, are in favour of the strictest temperance, but not of total abstinence. It is therefore pleasing to find a book written from the temperance standpoint dealing with the question in so temperate and practical a manner as the one before us. It consists of a series of papers reprinted from the *Temperance Chronicle*, the journal of the Church of England Temperance Society. They are written by a medical practitioner who it appears is a surgeon to a hospital and is in active practice, and they are primarily intended for the lay public. The earlier chapters are devoted to a brief consideration of thirst and an exposition in simple and clear language of the elementary physiology of the fluid exchanges of the body and of metabolism in general. Afterwards the pharmacology and toxicology of alcohol are described with especial reference to the effects of alcohol on body temperature and on the arteries. The conditions of arterio-sclerosis and of chronic Bright's disease are discussed in two separate chapters and the important part played by the abuse of alcohol in their production is strongly emphasised.

An interesting chapter is entitled "Alcohol in the Hospital." The author shows by statistics the lessened expenditure on alcohol in hospitals during the last two decades. He refers to the part played by Dr. Todd in replacing the indiscriminate bleeding which was formerly the routine treatment in so many diseases by the administration of stimulants, and insists that the reaction from describes his ingenious methods of obtaining records by means of the excursion of light rays from small electric lamps fixed to the jaw and illustrates his remarks with tracings thus taken. The last paper on Rheumatism and Chorea in Childhood is contributed to the Therapeutical and Pharmacological Section by Dr. L. G. Guthrie, and the discussion following it, in which Dr. Cecil Wall and Dr. D. B. Lees are reported at length, affords, *inter alia*, an interesting contribution to the controversy regarding the utility and dosage of salicylates in rheumatism.

Guy's Hospital Gazette.—The number of May 30th contains the second part of an interesting article upon some Aspects of French Medicine, by Dr. A. F. Hertz, in which he criticises the French method of examination of the chest with its habitual disregard of the stethoscope and bestows warm praise on the neurological teaching in Paris, particularly in the clinic of Babinski, whose explanation of hysteria the author fully accepts, including the doctrine that the hemi-anæsthesia occurring in that condition is frequently, if not always, induced by the suggestion of the observer.

St. George's Hospital Gazette.—The chief contribution to the May issue is an interesting memoir of Henry Gray, the anatomist, who achieved the Fellowship of the Royal Society at the age of 25 years and died only nine years later after having produced the text-book which made him famous. The article contains good reproductions of his portrait and of a letter of sympathy concerning his death written by Sir Benjamin Brodie.

London Hospital Gazette.—The number for May contains an excellent study in natural history, entitled, "Some Facts about the Cuckoo," which is enriched by reproductions of photographs depicting phases in the young bird's life which "P. H. B." is very fortunate to have secured. They should certainly find their way into the pages of some future work on ornithology.

Broad Way (Westminster Hospital Gazette).—The chief contribution to the number for May is an article on Spinal Anæsthesia, by Dr. V. B. Orr. A humorous interlude from the out-patient department from the pen of "C. I. V." includes this remark of a lady to the physician in charge, "Last time I come up with me chest, but this time I've come up with me insides."

St. Bartholomew's Hospital Gazette.—The number for June contains an account of the shooting range in the basement of the new buildings. It was opened on May 4th by the late treasurer, Lord Ludlow, who secured a bull's-eye in firing the first shot. In the same number Mr. D'Arcy Power contributes an interesting paper upon Early Surgical Consultations, in which he tells of the forerunners of the staff gatherings which form so well-known a feature of the routine of this ancient hospital.

The Edinburgh Medical Journal.—In the June number of this journal Mr. W. H. Battle recounts the various operative procedures devised for the treatment of femoral hernia and describes his own method which has proved very successful. Mr. J. Hogarth Pringle writes on a method of operation in cases of melanotic tumours of the skin; the growth is freely excised and the incision prolonged in the course of the lymphatic vessels, the glands being also removed with the tumour in a continuous strip. Mr. James Sherren contributes an interesting article on chronic neuritis of the ulnar nerve, due to deformity at the elbow joint, usually cubitus valgus; and Dr. Charles H. Mellard writes sensibly on the rôle of suggestion, hypnotic and other, in treatment. Dr. Alexander Don describes an easy method of excising piles without the use of special apparatus, a cork being inserted into the anus and the mucous membrane fastened to it by pins.

The Dublin Journal of Medical Science.—Under the title of "Some Unusual Pulmonary Cases" Dr. T. Gillman Moorhead records instances of idiopathic pneumothorax, of acute suffocative pulmonary œdema, and of staphylococcic pneumonia with small abscesses in the lung, secondary to pyelonephritis. A presidential address delivered by Dr. W. R. Dawson before the Section of State Medicine in the Royal Academy of Medicine deals with the relations between alcohol and mental disease. The author is inclined to commend the use of atropine as an adjuvant in overcoming the craving for alcohol and regrets that trial of hypnotic suggestion is not more often made. Dr. A. B. Mitchell deals with duodenal ulcer and calls attention to the occurrence of dilatation of the stomach in many such cases and to the relief of pain that may occur on first taking food.

The Scottish Medical and Surgical Journal.—Cases of traumatic asphyxia due to forcible compression of the thorax are not common. An interesting instance is recorded in the June number of this periodical by Sir George T. Beatson. The patient, a miner who was crushed by a cage, made a rapid recovery, but some optic neuritis supervened and it was feared that he would lose his sight. In a clinical lecture on various conditions affecting the skin Mr. Jonathan Hutchinson states his view that urticaria pigmentosa originates in bug-bites, and reiterates his belief in the piscine origin of leprosy. Dr. Byrom Bramwell analyses a series of 76 cases of poliomyelitis anterior acuta, and Dr. R. Dods Brown gives a brief account of the psychoses associated with influenza.

The Birmingham Medical Review.—The first of the Ingleby lectures for 1908, delivered by Mr. Christopher Martin at the University of Birmingham, is published in the May issue of this review. This lecture, which will also be found in THE LANCET of June 6th, p. 1603, deals with the dangers of uterine myomas and ends with an expression of opinion that operative interference is called for in the presence of serious symptoms rather than the old advice to wait for the occurrence of the menopause. In the same number appears the second of Sir James Sawyer's Lumleian lectures on Maladies of the Heart; among other points he writes in favour of the solid wooden stethoscope for auscultation in some conditions. Mr. A. Alison Bradburne records four cases of lesions affecting the optic tract.

The Medical Chronicle.—In the June issue is published the first part of an interesting article entitled "Opsonic Methods," by Dr. G. E. Loveday and Mr. Albert Ramsbottom. It deals with inoculations of tuberculin and of staphylococcic vaccine, presumably controlled by determinations of the opsonic index, though this is only recorded at the beginning of each case, its subsequent fluctuation not being noted. Hence the title of the paper seems somewhat of a misnomer. The results in each instance are estimated by the physician or surgeon in charge of the case, not by the inoculator. Dr. A. A. Mumford records three cases of Protracted non-assimilation of fat in children associated with defect in the biliary pigment but without jaundice. The probable cause was pancreatic defect, improvement occurring after administration of pancreatic extract, and in one case a well-marked "pancreatic reaction" (Cammidge) being obtained in the urine.

SOUTH AFRICAN CIVIL SURGEONS.—The sixth annual dinner of this association will take place on Friday, July 24th, at 7.45 P.M., at the Imperial Restaurant, Regent-street, when the chair will be taken by Mr. A. A. Bowlby, C.M.G. The Right Hon. R. B. Haldane, Secretary of State for War, will be present. It is hoped that those who wish to attend the dinner will communicate as soon as possible with Mr. C. G. Watson, 44, Welbeck-street, W. The price of the dinner will be 10*s.* 6*d.*, exclusive of wine.

four years of age and in acute tonsillitis and peritonsillitis. Ether, chloroform, and chloride of ethyl narcoses are passed equally carefully under review, indeed the minute directions given for the last leave nothing to be desired. The upright sitting position is treated with great clearness and the way to avoid dangers is pointed out, and the correct way to meet untoward occurrences is described, as well as the usual sequence of events during and immediately following anæsthesia.

Wintering in Rome. By A. G. WELSFORD, M.D., B.C. Cantab., F.R.C.S. Eng., &c., and G. SANDISON BROCK, M.D., C.M. Edin., M.D. Rome, F.R.S. Edin., Physician to the British Embassy in Rome. Second edition. London: The Health Resorts Bureau. 1908.—This excellent manual, as was pointed out in these columns,[1] had one defect and that was its too brief account of the water-supply in which Rome still holds the superiority that she has maintained over her European sisters from the early Republican era. In this second edition that defect has been fully remedied, its editors having diligently availed themselves of the best sources of information on the subject, beginning with the classic, "Analisi Chimica delle Acque Potabili della Città di Roma," executed as far back as 1884 for the Town Council by Professor Francesco Mauro, Dr. Raffaello Nasini, and Dr. Augusto Piccini, under the superintendence of Italy's greatest chemist, the Senator Stanislao Cannizzaro. Other and later analyses of quite recent date have also been studied with intelligence and care, so that the English-speaking reader, when resident in Rome, may have no hesitation in acting on the assurance that with her supply of 51,000,000 gallons of water per diem ("a more liberal supply than is found in any other city"), represented mainly by the Acqua Vergine, "a remarkably pure and clear water, well aerated, entirely without odour, and moderately hard (12·8°), with a constant temperature of 59° F.," Rome is better off in respect of this primary condition of life than any rival health resort in the world. A reperusal of the sections dealing with food and wine, choice of dwelling, outdoor exercise, and the avoidance of risks as to climate confirms us in the opinion which we have already given, that this manual for the winter resident in Rome leaves little, if anything, to be desired.

Home Nursing and Hygiene. By FLORANCE HUFTON-WINDUST (Diplomée), late Senior Lecturer on Home Nursing, &c., for the Surrey County Council; late Hospital Sister and Superintendent of Nurses. London: A. and C. Black. 1908. Pp. 122. Price 1*s*. net.—This little manual is intended for people with no training in nursing who have to take charge of sick persons in their own homes. It contains a straightforward and clearly written summary of the elements of nursing and though, of course, it cannot claim to be original the book fulfils a decidedly useful purpose. The temptation to include a symptomatological summary of various diseases has not been resisted but it has been kept within narrow limits, so that its readers are not likely to rely on it as a "family doctor" to the exclusion of proper medical advice. It is a pity that the section on "palpitation" follows immediately on the prominent heading "heart disease," as this conjunction may cause unnecessary alarm to nervous individuals suffering from functional heart trouble. But, speaking generally, the book appears to us to carry out well its purpose of instruction in the principles of home nursing.

A Text-book of Diseases of the Nose and Throat. By D. B. KYLE, Professor of Laryngology and Rhinology, Jefferson Medical College. With 219 illustrations, 26 in colour. Fourth edition, thoroughly revised and enlarged. London and Philadelphia: W. B. Saunders Company. 1907. Pp. 797. Price 18*s*. net.—Professor Kyle has immensely improved on his previous editions and amongst the points of merit in the book may be mentioned the very good reproductions of photographs of various microscopical preparations of pathological specimens. The descriptions of the various diseases are in the majority of instances extremely good, and were it not for Professor Kyle's great desire to prove that the sulpho-cyanides when present in saliva are capable of working so many ills in nasal diseases the work would take a higher position. A great many of the operations described are extremely good, though there is practically no mention of Killian's operation on the frontal sinus, which we consider to be a grave omission. No doubt there is throughout the work too great a tendency to subdivision. With these exceptions Professor Kyle's book, which has already made for itself a position in rhino-laryngological literature, will now occupy a somewhat higher place on account of the greater completeness of his treatment of the subject.

The City of London Directory, 1908. London: W. H. and L. Collingridge. Pp. 1202. Price 12*s*. 6*d*.—The edition for 1908 of this directory is the thirty-eighth. The editor states that works of reference are generally published at the close of the year, but the issue of the "City Directory" is intentionally delayed to enable him to take cognisance of the numerous changes that always occur in the first three months. The section concerned with the local life of London gives a full list of members of the corporation, arranged alphabetically and also according to the wards which they represent; a list of the committees, a valuable feature which it is claimed will be found in no other annual; and a list of the members of the London County Council and of the committees, the Directory being the only work of reference that gives this very useful information. The City Companies' section summarises the history of each guild and gives a list of the 9000 liverymen. There are the usual alphabetical street and trade sections and a carefully corrected map in colours of the City of London.

JOURNALS AND MAGAZINES.

Proceedings of the Royal Society of Medicine for May.—In the Clinical Section is an excellent paper upon Fatal Lymphocythæmia in Early Life, by Dr. J. Graham Forbes and Dr. F. S. Langmead, which contains a full study of 12 fatal cases of the disease and is illustrated with coloured plates of the affected organs. To the Electro-Therapeutic Section Dr. E. R. Morton contributes a paper on the Electrical Treatment of Atonic Conditions of the Digestive System, and the Epidemiological Section is occupied with an exhaustive report by Dr. J. F. R. Seheult on the Epidemic of Small-pox of Irregular Type in Trinidad from 1902 to 1904, an epidemic which caused so much trouble in its diagnosis. The paper is illustrated from photographs showing the skin lesions observed with startling realism. The Laryngological Section is devoted chiefly to reports of cases. In the Obstetrical and Gynæcological Section the pathology of ante-natal death is considered in a Case of Intra-uterine Death of the Fœtus occurring in Six Consecutive Pregnancies, with Observations upon the Importance of the Examination of the Fœtal Tissues for the Presence of the Spirochæta Pallida, in which Dr. H. Williamson and Dr. E. L. Holland support Schaudinn's claims concerning the specific nature of that organism in the causation of syphilis and the value of Levaditi's method in demonstrating it. The paper is followed by reports of cases by Dr. Herbert R. Spencer, Mr. Alban Doran, Dr. H. Macnaughton-Jones, and Dr. Kedarnath Das, whilst Dr. C. P. Longridge contributes a note on the Creatinin Excretion in Lying-in Women. The Odontological Section contains a Contribution to the Study of the Movements of the Mandible, by Dr. N. G. Bennett, in which he them or by secreting antidotal bodies? If certain fixed cells can, as seems proved, ingest bacteria, can they do so *proprio motu*, or do they need the stimulus or assistance of some substance present in the serum? Many are the questions awaiting solution: "multitudes, multitudes in the valley of decision." It is only by careful observation of clinical phenomena, conjoined with the arduous labour of research and experiment on the part of the laboratory worker, that the problems can be elucidated, and we must be grateful to all alike—to the clinician and the pathologist, to the critic and to the theorist—for aid in the great work that still lies before us.

[1] THE LANCET, April 27th, 1907, p. 1166.

The Lessons of Insanity.

THE application of the spirit and methods of the inductive sciences to the study of mind, which has been brought about very largely through the influence that psychiatry has exercised on normal psychology, has somewhat lessened the interest taken in the subjective symptoms of insanity. The hallucinations and delusions of the insane do not nowadays receive the same share of attention, are not recorded with the same detail, or analysed with the same minuteness as was customary when the principles of a purely introspective psychology were predominant. But though the eager investigation of the objective side of mind seems thus in some sort to have relegated the psychical facts to a less important place than the physiological facts which go with them or with which they go, these psychical facts are, of course, as essential to the positive psychologist as ever they were to the spiritualistic philosopher. Even the most strenuous believer in the superiority of the physiological standpoint in the investigation of the morbid mind must needs accept some part of his data from the subjective testimony of his patient: however clearly it be shown that a given hallucination is connected with a definite lesion of the cortex, or that a given emotional state is related to a definite condition of visceral disorder, the proof of the existence of these mental processes can only be furnished through the consciousness of the individual who perceives the hallucination or feels the emotion. On this account the psychical phenomena in insanity have necessarily as much importance for the materialist as they have for the spiritualist, and therefore the full and accurate recording of such phenomena is a matter which must be of equal moment to both. From this point of view a very special interest attaches to the accounts of their morbid imaginings which patients are sometimes able to give when they have recovered from their insane state. In many ways such autobiographical records are of higher value than the necessarily fragmentary and often deceptive descriptions of mental symptoms which are obtained in the course of the attack in response to the physician's queries; for the suggestive influence of the question, which so largely vitiates the accuracy even of sane testimony, is naturally far greater when exercised on the diseased mind where the questioner by some merely fortuitous intonation or turn of phrase may be all unconsciously awakening a whole train of new ideas or may be giving confirmation strong as Holy Writ to some fantastic product of the delirious mind. Of course, the retrospective view which the sane man takes of his insane thoughts has its own special chances of error, but these are different in kind, and for the most part so much less serious that they are more than outweighed by the peculiar advantages which belong to spontaneous testimony. Unfortunately the human documents of this sort which bear sufficient internal evidence of sincerity as to merit credence are comparatively few, and it therefore behoves us to welcome with gratitude any addition to their scanty number.

Such an addition, and one of no mean value, has been made by Mr. C. W. BEERS in the autobiography which he has recently published under the title, "A Mind that Found Itself."[1] The volume, which appears with a commendatory letter from Professor WILLIAM JAMES, relates the experiences of the author in the course of an attack of insanity which befell him when 24 years of age and which lasted through some three years, being characterised during the first two years by a condition of melancholic and persecutory delirium and during the third year by a state of sub-maniacal exaltation. As a contribution to our knowledge of the working of the insane mind the most valuable portion of the book is that which describes the feelings and ideas of the writer during the phase of depression. It is not, indeed, too much to say that the literature of insanity contains no more graphic and lucid account of the way in which the mind under the overmastering sway of a morbid emotional state interprets every impression in accordance with the delirious train of thought which that emotional state has begotten. This is, of course, no novel observation in the clinical history of insanity, but Mr. BEERS has delineated the process in his own mind so minutely and so vividly that his description will be something of a revelation even to those whom daily converse with the insane has familiarised with the strange subtlety of the distorted judgment in assimilating impressions to a dominant mood. The only fault to be found with this most fascinating picture of the insane mind from within is that the author has not sufficiently separated the record of his experiences from the statement of the inferences regarding matters both of theory and of practice to which these experiences have led him. The work would have gained, at all events in dramatic effect, if the unfolding of the series of delirious conceptions had not been too frequently interrupted by psychological comment and by criticisms of medical and administrative methods which, though in many cases just and valuable, might well have been relegated to another part of the volume. This intrusion of secondary questions is still more evident in the writer's account of his maniacal phase and detracts very much from its value—a fact which is the more regrettable because the literature of psychiatry is sadly lacking in records of the subjective side of states of emotional exaltation.

Passing now from the purely psychological aspect of Mr. BEERS's book to his strictures on present methods of treating the insane, we may note with pardonable gratification that the point on which he lays most stress is the enormous value of that principle of "no restraint" which has so long been an honourable tradition of alienist practice in this country. In commending this principle as the first condition for the rational treatment of the insane,

THE LANCET.

LONDON: SATURDAY, JUNE 27, 1908.

The Defensive Arrangements of the Body.

OF all the problems of pathology none is more fascinating than that presented by the phenomena of immunity and resistance to infective diseases; indeed, this subject alone embraces a large portion of the field of modern medicine. The advances in knowledge in this direction which have taken place within the last few years are remarkable and hope has been continually aroused that at last we were on the point of discovering a mode of treatment which would enable us once for all to meet our parasitic invaders on something like equal terms, and which would ultimately abolish from the category of human ills many of our most virulent scourges. The success attending the use of diphtherial antitoxin led us to hope that similar antidotes might be prepared for all other microbial diseases. The discoveries which arose out of PFEIFFER'S observations on the fate of cholera organisms in immunised animals suggested another great mode of defence which might be exploited therapeutically. And most recently of all the successes obtained with vaccines consisting of dead bacteria, controlled by estimations of the opsonic content of the serum, have led sanguine experimenters to anticipate the inauguration of a medical millennium when the methods of the surgeon and the physician would alike be relegated to the lumber room, leaving a free hand to the scientific procedures of the beneficent inoculator. Yet as the wave of enthusiasm excited by each new discovery has passed away we have been reluctantly obliged to confess that, while definite gains have in every case accrued, we are yet only a little nearer to the goal of complete knowledge, for the field of employment of the new remedies is sadly limited after all. There are more things in heaven and earth than are yet dreamt of in our pathology, and it is at least probable that we have so far only touched the fringe of the great problem of immunity, the most important factors in which have still to be discovered.

The thoughtful address delivered by Professor W. WATSON CHEYNE before the Society for the Study of Disease in Children, which appears on another page, calls attention to a number of peculiar phenomena in the defensive arrangements of the body which are not satisfactorily explained on any of the existing theories. Why are children more susceptible to certain infections than adults, and less so to others? Why are certain tissues prone in early years to suffer from the attacks of particular germs, while in later life other parts of the body are more often the seat of the disease? The pneumococcus seems on the whole more able to establish itself in children than in adults: it attacks not only the lungs but serous membranes and joints. Yet pneumonia is more fatal in adults, especially in those over 40 years of age, than in the young. The gonococcus is also specially virulent for children, yet it does not in them produce the articular troubles from which older persons may suffer, although joint disease due to other germs is notoriously common in the young. The reason for these differences is quite obscure. The tendency of the skin of children to be the seat of abscesses and of impetigo, while boils are rare at this period of life, may perhaps be explained by the delicacy of the outer epidermis; but can the tendency of ringworm to die out spontaneously after puberty be similarly explained? The latter event seems rather to point to an alteration in the chemical environment of the fungus which stops its further growth. Yet ringworm of the body is not unknown in adults. But if children are more liable to most infections than their elders, the latter have compensating troubles. In them the processes of repair are less active and the power of recovery is less. Acute illnesses are thrown off with difficulty; slighter maladies tend to become chronic rather than to disappear. In the skin slight irritation may give rise to most rebellious eczema which persists in spite of remedies which in youth act on it like charms. In the joints trifling injuries too often set up permanent lesions which result in serious crippling. What is this mysterious recuperative force which we can recognise but not identify? It can hardly be the same as the tendency to growth, though to some extent it may coincide with it, for it is in rapidly growing parts that some infectious agents especially tend to establish themselves—witness the suppurative lesions of the epiphysial cartilages in children. Is it in some way dependent on the influence of the nervous system? The similarity between some chronic senile changes in joints and the acuter lesions described by CHARCOT might seem to support such a view, and Professor CHEYNE points to the interesting researches of Mr. G. L. CHEATLE on the limitation of certain diseases to areas supplied by particular nerves as additional evidence of such an influence. The part played by mental states and emotions in modifying the course of diseases is also beyond doubt. Yet of the nature of this nervous influence we know nothing.

As to the exact mechanism which is brought into play in the defence of the body against infective germs we have already alluded to the antitoxic and bactericidal agencies which are involved. The fluids of the body and the leucocytes are now proved to possess properties which aid us in our fight with bacterial invaders, and we know that they act not only separately but as necessary allies in the process of phagocytosis. But behind these agencies there is the great body of tissue cells, and Professor CHEYNE states his opinion that "the essential resisting power of a part as regards local infection lies in the tissue cells rather than in the adventitious leucocytes which come into it subsequently." That this dictum is true it seems impossible to doubt, for how else can we explain the curious features of localisation of certain infections in particular tissues and organs? The muscles are seldom affected by tuberculosis, the lungs almost invariably when the disease is at all generalised. Yet both parts are bathed by the same blood stream and are thus in contact with the same serum and the same phagocytes. Of this cellular resistance, again, we know practically nothing. Is it a mere passive power of withstanding bacterial toxins, or do the cells actively combat the germs by destroying maxillæ. The effect on the bones is seen in two regions—namely, in that of the premaxillæ and the developing molars. In nasal obstruction the function of the nose is in abeyance, the muscles of the nostrils being functionless; the result of this is a marked arrest in the growth of the premaxillary portion which shows itself in crowding of the deciduous incisors and subsequent crowding of the permanent incisors. The effect on the growth of the permanent molars is due to the lack of expansion of the antrum. Dr. A. KEITH has shown that growth of the maxilla and the expansion of the antrum are closely related. It therefore follows that anything that interferes with the orderly expansion of the antrum must exercise a prejudicial effect on the growth of the part of the maxilla containing the developing molars. This interference is marked in nasal obstruction, with the result that there is a lack of growth of the posterior part of the bone and a corresponding crowding of the molars. So marked is this that the first permanent molars will in erupting produce absorption of the posterior part of the second deciduous molar and so occupy an abnormal position in relation to the lower teeth. A further point to be remembered is that the growth of the mandible is correlated with that of the maxilla, and as Mr. J. G. TURNER has shown the arrangement of the teeth in the arch is mainly due to the growth of the bone. These facts are sufficient to show that in considering the cause of any abnormal arrangement of the teeth the relation of the body of the bone to the tooth must be considered and a classification should be based on etiological lines. This point seems to us to be ignored by those who consider that occlusion is the fundamental principle of the treatment of irregular teeth, while a weakness of those who follow the system of treatment advocated by Mr. HIGHTON in the classification of their cases must be noticed. The first molar is chosen as the key to occlusion, and there might be something to be said for this if it could be shown that the position of this tooth to the rest of the bone was constant; but it is not, and only too often we find that though the molars are in *correct occlusion* they are displaced forward in both jaws owing to interruption with growth. In brief, the condition seen in the majority of cases is a crowding of teeth due to want of growth of bone; the normal relationship between teeth and jaws does not exist.

Nor are we satisfied that the method of treatment advocated under the name of "orthodontia" effects its purpose, while we think that the purpose is based *upon errors in conception*. In the operation, which consists in making the teeth assume a larger arch by means of various mechanical contrivances, the crowns are mainly affected, the roots of the teeth still retaining their former crowded position. It seems to us that this treatment, though often alluded to as quite modern, was introduced at least 25 years ago and was much practised with results which to a great extent might have been anticipated—namely, a relapse of the teeth to their former position, in addition to after-results on the soft tissues of the prolonged use of mechanical contrivances which the treatment by expansion necessitates. The paper by Mr. COLYER, although not covering the whole question of the treatment of irregular teeth by extraction, is sufficient to show the results that can be obtained in the treatment of prominent teeth by extraction, a method which would appear more rational inasmuch as it is founded on the relation of the teeth to the bone. That timely interference by the extraction of teeth will reduce the amount of mechanical treatment to the minimum seems to be recognised generally, and that permanent results ensue is not challenged. This being so, the uncertainties of the other treatment would seem to condemn it. The claims made that extraction of the teeth for irregularity tends to abnormal facial expressions cannot be substantiated and from an æsthetic point of view treatment by intelligent extraction gives excellent results. Thousands of patients testify to this by their countenances when looked at and by their jaws when these are examined. As far as the treatment of irregularities of the teeth is concerned, having regard for the well-being of the organism, extraction carried out intelligently is to be preferred to methods necessitating the prolonged use of mechanical contrivances. A functionally healthy mouth is more likely to be obtained the less the teeth are interfered with by mechanical means.

Annotations.

"Ne quid nimis."

THE ROYAL COLLEGE OF SURGEONS IN IRELAND AND THE UNIVERSITIES BILL.

THE Prime Minister, having been approached on the subject, consented last week to receive a deputation consisting of the following Members of Parliament who desired to represent to him the claims of the Royal College of Surgeons in Ireland to a grant from Government to help to maintain the medical school of the College, which, as our readers have already learned from our columns, will be placed at a serious disadvantage by the State-aided competition about to be set up by the new medical school in connexion with the new university in Dublin: Right Hon. Sir Edward Carson, Right Hon. James H. Campbell, Mr. S. H. Butcher, Sir William Collins, Mr. Cecil Harmsworth, Dr. A. E. W. Hazel, Sir Joseph Leese, K.C., Right Hon. Walter Long, Mr. Ramsay Macdonald, Sir Philip Magnus, Mr. J. C. O'Donnell, Mr. R. W. Perks, Mr. H H. Raphael, Mr. Duncan Schwann, Sir Albert Spicer, Bart., Sir John Batty Tuke, and Sir George White. Mr. Asquith received the deputation at the House of Commons on June 16th. Sir Edward Carson introduced the Members who were accompanied by the President of the College, Mr. John Lentaigne, the Vice President, Mr. R. H. Woods, and the ex-President, Sir Henry Swanzy. The President stated the grounds upon which the Council of the College rests its claim. Mr. Butcher, Sir William Collins, Sir John Batty Tuke, Sir Albert Spicer, Sir Edward Carson, the Vice-President, and Sir Henry Swanzy also spoke. Mr. Asquith replied in sympathetic terms with a promise to give the matter the fullest consideration, and it is to be hoped that he will be as good as his word. Prime Ministers, when they consent to receive a deputation, can hardly dismiss their petitioners with other than friendly promises, but the matter of the Royal College of Surgeons in Ireland is urgent. On Friday, during the discussion of the Irish Universities Bill in Standing Committee, Mr. Birrell intimated his intention of leaving the relations of the Royal College of Surgeons in Ireland with the new university in Dublin—if any were established—to be dealt with by the senate of the new university, on the ground that the College was not desirous of affiliation so much as of a Government grant. This may be so; but we trust that the

Mr. BEERS rightly emphasises its connexion with a larger truth which, though it is accepted as a commonplace, has yet to find its full recognition in practice—the truth, namely, that psychiatry is a part of medicine and that its progress in the future depends on its sharing in the vivifying movement of general medical science. And here we may note as a striking and significant fact that the conclusions to which his subjective view of insanity thus led this singularly acute and observant patient are precisely the same that have been recently urged on the attention of the public by the alienist physician whose name is most intimately associated in this country with the advocacy of objective methods in the study of mind. Dr. HENRY MAUDSLEY has told us that one of the chief motives which have prompted his generous offer to endow a hospital for mental diseases in London is the desire "to break down the unfortunate isolation from general medical knowledge and research in which the study and treatment of insanity remains." It is assuredly eloquent of much that the patient who has seen insanity from within and the psychiatrist whose life has been devoted to studying it from without should thus be at one in the belief that the treatment of the insane will be effectual and humane in proportion as it is guided and inspired by the same principles that have guided and inspired the application of medical science to ordinary physical disease. And if psychiatry thus stands to gain by being brought into closer touch with general medicine, it is no less certaint that medical culture must profit by the training which a scientific study of diseased mind is well fitted to impart. The value of that training and the aid which it gives to the apprehension of the vital issues in the biological and bio-social problems of gravest moment to humanity have been amply shown in the writings of workers in this branch of medicine. To quote a specific example it would suffice to glance through the pages of the modest volume which has just appeared from the pen of the distinguished physician to whom we have referred above.[2] It would be hard to name a more temperate and lucid criticism of the theories that agitate the world of biology than that which Dr. MAUDSLEY has compressed into his brief essay on "Heredity, Variation, and Genius"; while as an example of what the philosophic physician can contribute to the analysis of æsthetic quality and psychological characterisation in literary art the study on "Shakespeare Testimonied in his own Bringingsforth" is entirely admirable. If we may assume that these writings are in some degree the results of the discipline of psychiatry we shall augur well of its wider influence in medical education.

The Correction of Irregularities of the Teeth.

IN the present issue we publish two articles, one by Mr H. C. HIGHTON and the other by Mr. J. F. COLYER, bearing on the treatment of abnormal positions of children's teeth. The subject is of great interest to us all, and especially to the general practitioner, inasmuch as he is often consulted by parents in such cases, while the public has begun to find out that when more than one opinion has been sought totally divergent methods of treatment may be suggested. The last 30 years have seen a great increase in the number of individuals presenting a crowded condition of the teeth and attention has been concentrated on remedy of the deformity, with the result that a method of treatment has been adopted in some schools which appears to many observers to be to a great extent empirical. Within the last decade a theory has sprung up that the fundamental principle underlying the correction of irregular teeth is an understanding of the normal occlusion of the teeth. These views are set forth with clearness and in detail by Mr. HIGHTON in his article, where it will be noticed that the classification of the various deformed arches and jaws centres around the position of the first molar tooth. Normally, the maxillary molar should occlude with the posterior two-thirds of the mandibular tooth, the outer cusps of the upper tooth overlapping those of the lower. Three classes of malocclusion, to use Mr. HIGHTON'S term, are recognised—the first in which the position of the molars is normal, the second in which the maxillary tooth is occluding too far forward, and the third in which the mandibular tooth is occluding too far forward. By far the larger number of cases of irregularity met with belong to the first class. No consideration is taken in the classification of the position assumed by the irregular teeth, whether protruding, rotated, instanding, and so on. The treatment aims at the restoration of normal occlusion, and the principle underlying it is the "expansion of the arch," though how far the arch is really expanded will be seen to be doubtful.

In order to criticise this method of treatment it is necessary to consider briefly some elementary facts connected with the development and the growth of the jaws. If the skull of a child about the age of four years be examined it will be noticed that the developing permanent teeth are situated in the substance of the bone in an irregular manner. In the maxilla the permanent incisors are posterior to the deciduous teeth, the lateral incisors being as a rule in a plane posterior to that of the central. The premolars are embraced by the roots of the deciduous molars and the canine tooth lies high up in the nasal process in a plane external to the other teeth. The first permanent molar is situated in the tuberosity of the bone, with the occluding surface looking outwards and backwards, and above this tooth is the second molar with its occluding surface looking still more backwards and outwards. A somewhat similar crowded arrangement exists in the mandible. In other words, the growth of the teeth precedes the growth of the jaw, and in order that the teeth when erupted may be arranged in a normal manner it is necessary that orderly growth of the jaw should continue up to adult life. If this orderly growth does not take place, then we find that the teeth appear in the arch in an irregular manner. There would seem to be two main factors on which the growth of the jaws is dependent—viz., the proper carrying out of the function of mastication and nasal respiration. Much importance is placed by many on the former, but it is probable that on the lack of nasal respiration we must look for the main factor that retards the proper growth of the jaws, and the earlier the advent of nasal obstruction the greater will be the interference with the growth of the suddenly increase in glycosuria and symptoms of coma may follow. The oatmeal may be taken as a thin soup or gruel, or it may be made more palatable by making it into masses like meat balls or sausage cakes and frying them until brown on the outside. An explanation of the value of the diet is not easy. The 250 grammes of oatmeal contain about 150 grammes of starch. It is well known that a too rigid exclusion of carbohydrates may lead to acidosis and coma. Possibly the starch of the oatmeal may furnish the oxygen molecule that is needed for the process of oxidation by which oxybutyric acid is converted into diacetic acid, acetone, and finally into water and carbonic acid. Perhaps one kind of starch, such as oatmeal starch, is better tolerated than another. In some of the cases under the oatmeal diet the substitution of another carbohydrate, such as cane sugar or wheat starch, increases the glycosuria. When Dr. Herrick began to try von Noorden's treatment he was very sceptical. He doubted whether the stomach would tolerate from 20 to 50 monotonous and far from tempting meals. He was unable to understand the disappearance of sugar from the urine when such large amounts of starch were given and the statement that severe cases were benefited while mild cases might be made worse seemed paradoxical. But the good results astonished him. The following is an example. A man, aged 37 years, had neuralgic pains in the back and a small ischio-rectal abscess. He had not lost weight or noticed polyuria, but for several years he had drunk water freely and was subject to boils. The urine in the 24 hours amounted to 1800 cubic centimetres and contained 108 grammes of sugar. Under the ordinary diabetic diet with two slices of bread daily the sugar fell to 98 grammes. Under the oatmeal diet the sugar in ten days fell to 1·5 grammes. Meat and vegetables were added and in a few days the sugar disappeared. In the severe form of diabetes of the young the results were gratifying. In the last 12 months Dr. Herrick has seen four cases of typical diabetes in girls under the age of 17 years. Some improvement took place under a strict diabetic diet, but there remained much thirst, polyuria, and glycosuria, and the patients seemed likely to go the usual way of the youthful diabetic. In each case the response to the oatmeal diet was prompt and in three the glycosuria disappeared for a time.

HOLIDAY PRECAUTIONS.

THE season is with us when people begin to discuss the question of where to go for a holiday and great railway and steam shipping companies are making a point of the special inducements which they are able to offer to the public in the way of health resorts and trips. There are guides and pamphlets innumerable and so much are the convenience and comfort of the would-be traveller studied that even a list of farmhouse lodgings, apartments, board and residence, and so on, is published and sent to him gratis with the view of relieving him at any rate of some of the anxiety which the choice of a holiday entails. He is informed where good golfing, fishing, shooting, and bathing may be had; he is further instructed as to the accommodation which a given house offers and as to the distance from station and other particulars, all of which, of course, are interesting enough and of more or less moment. Of the greatest moment, however, are the questions relating to the sanitary condition of such places and the fitness and adequacy of the water-supply for drinking purposes. Yet these questions are seldom faced until the premises are decided upon—until, in fact, they come to be occupied. At all events it is only occasionally if at all that any reference is made in the lists of lodging-houses to matters concerning water-supply and the general sanitary arrangements of the houses offered as tempting temporary homes for the person seeking holiday. In the absence of any trustworthy information on these heads he may be plunging himself and his family into a veritable death-trap. It must not be forgotten that, as a rule, the sanitary conditions of our cities and towns are satisfactory and the water-supply abundant and pure, conditions which often enough are hard to secure in the remote seaside or country village. Further, the mysterious immunity conferred upon the inhabitant who perhaps has all his life been drinking impure water is not enjoyed by the visitor. Instances are not wanting of enteric fever breaking out amongst soldiers on the march through drinking typhoid-infected water and yet the same water had been consumed by the natives for years without any harm resulting. The boy who lives over the insanitary stable is often healthy enough, but this method of living suddenly introduced to a person used to a carefully guarded sanitary environment might prove to be a serious menace to his health. People sometimes come back from their holiday with a septic throat and often the explanation of its origin is found in the defective sanitary conditions of the lodgings which they occupied. It is a pity that some scheme cannot be introduced by which a guarantee so far as that is humanly possible could be supplied to the effect that the boarding-houses, apartments, and so forth, in seaside and country places are in good sanitary condition and that the water-supply above all is free from suspicion. As it is, money is often wasted and the health prejudiced by a holiday spent under insanitary conditions, to negative which no amount of good sea or country air can suffice.

THE CUTANEOUS REACTION TO TUBERCULIN IN CHILDREN.

Von Pirquet recently described a reaction characteristic of tuberculosis which is obtained on scarifying the skin and inoculating a minute quantity of tuberculin. The site of inoculation becomes red and swollen and within 24 hours a small papule develops. In healthy subjects even a slight reaction is exceptional. Subsequently Calmette described a reaction obtained on instilling tuberculin into the conjunctiva which in consequence of its simplicity and trustworthiness eclipsed the cutaneous reaction and in a remarkably short time became popular throughout the world. But later experience showed that the conjunctival reaction is sometimes followed by severe conjunctivitis and ulceration of the cornea. At the meeting of the Société Médicale des Hôpitaux of Paris on May 15th M. J. Comby read an important paper on the cutaneous reaction in children. He extolled this reaction and claimed for it the advantage over Calmette's reaction of complete innocuousness. He ascribed its want of popularity to the fact that its method of use (the number of scarifications of the skin, their depth, and the dose of the tuberculin) had not been laid down definitely. He has elaborated a method which has the advantages of complete innocuousness, ease of execution, and certainty in diagnostic indication. He uses the 1 per cent. solution of tuberculin of the Pasteur Institute, which is also used for the oculo-reaction. Instead of scarifications, which are a little painful and to which patients object, he makes three pricks with the vaccine lancet in the deltoid region, telling the patient that he is going to vaccinate him. On the next day and on the day after that he observes the result. If there is no reaction only traces of the pricks can be seen—three small black spots without surrounding redness. If the reaction is positive, after 24 hours, perhaps a little later, there is a more or less intense redness around the pricks. This is followed by papules which last from eight to ten days. Several degrees of reaction can be distinguished: (1) slight redness, simple erythema; (2) red papules, papular erythema; (3) red papules with vesicles; (4) red papules with bullæ; and (5) red papules with central eschar and a ring of vesicles resembling

College will not be left stranded between the two courses and subjected thereby to cruel rivalry. If no grant comes because the senate may later devise some satisfactory scheme of affiliation, and if no plan of affiliation materialises because it is understood that the College would prefer a grant, the position of the College will be a very *difficult one. Why need either the Government* or Mr. Birrell, as spokesman for the Irish Universities Bill, remain longer silent?

LABORATORY TECHNIQUE AS A CAUSE OF FAILURE IN THE SEARCH FOR THE BACILLUS TYPHOSUS.

NEGATIVE results so often attend the search for the *specific bacillus typhosus even when there is no doubt that* the water-supply is the *fons et origo mali* that any suggestion which is likely to remove this reproach from bacteriological methods should be of the utmost value. In a paper recently sent to us by Dr. D. Rivas, bacteriologist to the laboratories of the Department of Health of the Commonwealth of Pennsylvania, University of Pennsylvania, Philadelphia, he *records an occasion* when he *chanced to compare* the general count of bacteria per cubic centimetre in the same water on plain neutral agar and litmus lactose agar with the result that he found that the litmus agar exerted a very decided restraining action on the growth of bacteria in water in general. At the present time litmus lactose agar culture medium is generally used as a differentiating agent, the bacillus coli producing a pink colouring and the bacillus typhosus a violet or blue colouration. The Parietti solution (hydrochloric acid and phenol) used in many laboratories is subject to criticism also. In the experiments in some *instances no colonies grew on litmus* lactose agar plates, while *from 100 to 1200 were present on plain agar.* In a closer study of these results it was suspected that such restraining action was common only to a certain kind of bacteria of no importance in the bacteriological examination of water from a sanitary point of view, as stated by the advocates of this medium. In extensive experiments with 24 and 48 hours old bouillon cultures of bacillus typhosus and bacillus coli, diluted in sterile water, made simultaneously on plain and lactose litmus agar, it was found that in general the number removed by litmus agar was about 34 *per cent. for bacillus typhosus* and about 30 per cent. *for* bacillus coli. The next question was whether the litmus could be more detrimental to a certain form of bacillus typhosus and bacillus coli—that is, whether it would be possible that in the life-cycle of this organism there might exist a certain age, the very young or the very old form, at which they were more *sensitive* to the litmus; and with this point in mind another series of experiments was made with bacillus typhosus and bacillus coli after two, three, four, six, 12, 24, and 48 hours, as well as after *five*, ten, 15, and 20 days and after one month's incubation at 37° C. and also at room temperature of bouillon cultures exposed to diffuse daylight. It was found that the removal by the litmus after from one to five days was 60 per cent. for bacillus coli and 65 per cent. for bacillus typhosus, from 10 to 15 days it was about 80 per cent. *for bacillus coli* and 90 per cent. for bacillus typhosus, and from 15 to 20 days or one month of incubation it was 95 per cent. removal for bacillus typhosus. Further, one to *five* days old cultures showed *from one* to eight bacillus coli and ten to 350 bacillus typhosus colonies per cubic centimetre on plain agar and none on litmus agar; from *five to* ten days there were samples which showed from 10 to 18 bacillus coli and eight to 560 bacillus typhosus colonies per cubic centimetre on plain agar and none on litmus agar; from 10 to 15 days samples gave as many as 6000 bacillus typhosus colonies per cubic centimetre on plain agar and none on litmus agar. And *finally, from 15 days* to one month old cultures there were samples giving from 4 to 20,000 bacillus typhosus colonies on plain agar and none on litmus agar. The addition of 1 to 2 per cent. Parietti's solution and the amount of litmus tincture added to the medium were in direct proportion to its germicidal action on both organisms. Ordinary temperatures and exposure to diffuse daylight were more detrimental *to* bacillus *coli* and bacillus typhosus cultures. Von Drigalski and Conradi and Endo and other methods also have been investigated and they have *shown the same* germicidal action as litmus and Parietti's solution. These experiments show, Dr. Rivas thinks, in the most positive manner the inaccuracy of our present technique and methods in the bacteriological examination of water and also show the gradual degeneration of bacillus typhosus and the detrimental action of litmus and Parietti's solution upon the culture as it grows older. Such experiments demonstrate possibly the cause of failure in the detection of this organism in water. If such degeneration of bacillus *typhosus takes places under favourable* conditions for its life, there is good reason to believe that it will be greater in water; and the negative results *which usually accompany a search for the bacillus typhosus* in water supplied to a community where an epidemic of enteric fever has just broken out may, in the light of these results, be due to the fact that the organism is present at such a phase of its life cycle that it easily yields to the detrimental effect of litmus and Parietti's solution. This degenerated phase may, of course, be *due to the biological* processes in water. From the above results Dr. Rivas concludes not only that the present methods are at fault but also that by using litmus and Parietti's solution or the von Drigalski *or* Endo medium *it* would seem as if the work carried out under the most exact technique was devised to arrive at a negative result. This is especially the case for *bacillus typhosus. No doubt as a means* of differentiation all the above media are of more or less importance, but their value as to the isolation of this micro-organism from *water he believes to be most uncertain.*

OATMEAL DIET IN THE TREATMENT OF DIABETES.

IN 1903 von Noorden *advocated in certain cases* of diabetes a *diet* consisting daily of from 250 grammes of oatmeal, from 250 to 300 grammes of butter, and 100 grammes of some vegetable albumin. For the last six to eight eggs, or the whites of eggs, may be substituted. The oatmeal is cooked thoroughly in water for about *two hours* and *the butter* and *eggs are* well stirred in when the oatmeal is nearly cooked. Salt is added to suit the taste. This method of treatment has received *little notice*, but in the *Journal of the American Medical Association* of March 14th Dr. James B. Herrick has reported some remarkable cases in which it appeared to be valuable. Von Noorden claims *that in many cases of severe* diabetes, especially those in which the ordinary strict diet fails to rid the urine of sugar and when the persistence of acetone *bodies in the urine and other symptoms cause* fear that coma is impending, this *diet* will remarkably diminish the glycosuria and will cause the acetone bodies to disappear. *Further, an increased* tolerance for carbohydrates develops and an amount of starch which before would have increased the thirst and saccharine polyuria is now taken with benefit. He does not claim that the milder *forms of* diabetes are benefited; indeed, they may be made worse. In the severe cases, too, the diet *sometimes fails, so* that *selection* of cases is necessary. The diet is to be maintained *for one* or two weeks and then the ordinary diabetic diet—*i.e.*, a proteid and fat diet with *sufficient carbohydrate to prevent* acidosis—*is to* be resumed gradually. *If it is* resumed in the territories belonging more directly to the Crown but also in those of the ruling chiefs of the native States, in which the erection of female hospitals has been encouraged, and advice has been given and lady doctors have been provided on request by the chiefs to the head committee. The natives of India evidently believe in the art of healing as taught by English medical men and women. But the benefits bestowed through the knowledge of our English medical science are not the only good results; through the influence of the female medical practitioners employed the rigid rules of seclusion as regards Indian females are gradually becoming relaxed, the lifelong seclusion of married women is no longer so strictly enforced, and under the improved state of affairs some of the highest Indian ladies are now receiving even male visitors. What a blessing this breaking down of the deadening seclusion must be to these people who have hitherto been practically prisoners in their own homes. Dr. D. N. P. Datta pleaded eloquently at the annual meeting of the friends and supporters of the North India School of Medicine for Christian Women at Ludhiana for the greater liberty of the native women of India, so that they might enjoy the same blessings as their enlightened European sisters. He spoke of newly married girls who during their first year of married life had longed and yearned for the old outdoor life with its sight of birds, flowers, plants, and the expanse of the hillside. This intense longing, however, consequent on the customs hitherto existing in India had become gradually deadened but this deadening was much to be deplored. Happily under the beneficent influence of the Countess of Dufferin's humane association a brighter future seems about to arise.

THE AMBULANCE SERVICE AT THE JUBILEE PAGEANT IN VIENNA.

THE great Jubilee pageant which took place before the Austrian Emperor in Vienna on June 11th in celebration of the Jubilee of his accession to the throne was the occasion of much thought and elaborate organisation on the part of those in charge of its details. No fewer than 12,000 persons in costumes and armour representing every phase of the national history, with 4000 horses, filed past the Emperor, and more than half a million of his subjects shared the spectacle with their venerable monarch. But the complete enjoyment of the great gala day depended on less conspicuous workers than those who marched in the procession and the arrangements for the public comfort and safety were the cause of no less anxiety to the responsible officials than was the pageant to its marshals. This anxiety was intensified by the fact that when 80,000 school children had paid their duty to the Emperor a few weeks previously there had been such a lamentable lack of drinking water and lavatory accommodation as to cause considerable suffering to many of them. Since that time the weather had been hot and dry and the probability of many cases of sudden illness occurring was made all the greater by the fact that a large number of the sightseers, of whom not more than a quarter could find seats in the tribunes, were to be in their places for nine hours from 6 o'clock in the morning on each side of a route nearly 10 miles in length. In spite of this the physical requirements of that huge assembly were met with complete success. Public lavatories were erected every few hundred yards all along the line and an abundant supply of fresh cool water was available at all points. The Vienna Rettungsgesellschaft (Street Ambulance Corps) provided 20 stations, with 216 medical men in attendance, but amongst the whole concourse only 350 casualties needed treatment, most of which were slight attacks of fainting, with a few cases of heat-stroke and minor accidents. We are informed that the excellence of the arrangements evoked universal gratitude from the Viennese public, and indeed it may serve as an object-lesson outside Austria showing the extent to which the public depends upon an organised medical service for the prime necessities of its well-being.

"THE OLDEST INSTITUTION FOR TREATING SICK CHILDREN."

A LARGE circle of the medical profession will learn with sympathy that Sir Samuel Wilks has been laid up by a serious operation for the second time within a few years. We are very pleased to have had evidence of his convalescence in a letter which he has written to us concerning the first children's hospital in defence of the claims of the Royal Waterloo Hospital for Children and Women to the honour of that title. He says: "I was physician there in the fifties and had a few cribs there. When I saw out-patients and there was a child too ill to be taken home (perhaps with pneumonia) I recommended admission, and if there was an empty bed I took it in. Of course, the cots were few, as were the women's beds in so small a place, but children were taken in." The letter which called forth this reply from Sir Samuel Wilks was from the secretary of the Hospital for Sick Children in Great Ormond-street and was published in our issue of June 13th, p. 1716. It stated that "The treatment which the Royal Waterloo Hospital afforded before 1852 ...... and for many years after that date, was dispensary treatment only." It will be seen that Sir Samuel Wilks's statement controverts the last statement. The interest in medical affairs which has led the veteran physician to champion the claims of his old hospital will surprise none who are aware of the enthusiasm and energy which he still displays in the progress of his art, and especially in the defence of medical research. We take this opportunity of expressing our hope that he may be restored speedily to complete health and may long remain a pillar of the society lately inaugurated to promote the great cause which he has so much at heart.

THE SITUATION OF DERMOID CYSTS.

A DERMOID cyst is caused by the inclusion of a portion of the skin at some part of the body where a cleft exists during development and closes later. Thus they are found in the lines of any of the embryonic fissures of the face; especially do they occur at the outer end of the orbital fissure, but they are also found in the lines between the fronto-nasal process and the maxillary processes and in the oral fissure. Dermoids may also be found in the middle line of the trunk anteriorly where the somatopleures close, and posteriorly where the dorsal folds meet. In the labium also and in the scrotum dermoids may be found, and it is probable that all those cysts which have been described as dermoids of the testis are really dermoids of the scrotum. The cysts which have been described as dermoids of the ovary are in all probability teratomata, that is to say, suppressed fœtuses. A distinction has been drawn between the dermoids just described, which have been called somewhat barbarously "sequestration dermoids," and those dermoids which arise in connexion with canals which exist in the fœtus but normally disappear before birth; these dermoids are called tubulo-dermoids. The distinction is practically useless and it results mainly from a want of recognition of the fact that cysts of two kinds may arise in connexion with developmental canals. In one variety the cyst is a true dermoid, exactly similar to those developing in the sites of the facial clefts; its walls are formed of skin and it may contain hairs. In the other form the cyst is derived from a survival of a part of the canal itself; the walls are formed of a stratified epithelium without hair follicles or sweat glands, and hairs are not found in the contents. The diagnosis of anthrax, papulo-necrotic erythema. The last three, and especially the last two, forms are very rare. None of the reactions are serious or produce adenopathy or fever. Complete recovery takes place in one or two weeks. This reaction is applicable at all ages and in all forms of tuberculosis. In the immense majority of cases the cutaneous reaction, like the ocular reaction, is positive only in tuberculous children and is negative in those free from the disease. However, in cases of subacute infection (*granulie*) and in cases of advanced pulmonary tuberculosis the cutaneous reaction, like the ocular, may be negative. Sometimes the cutaneous reaction is negative in a patient who is very ill but becomes positive when he improves (when the temperature falls, strength is regained, and the pulmonary focus dries up) Conversely, when the reaction is positive while the child is fairly well it becomes negative when he becomes ill. The negative reaction in advanced tuberculosis is not an important drawback of the method. The important point is to recognise tuberculosis in its initial stage when the reaction is of service.

THE STATUES ON THE NEW BUILDING OF THE BRITISH MEDICAL ASSOCIATION.

IT is sincerely to be hoped that the authorities of the British Medical Association will turn a deaf ear to the suggestion that the simple and forcible figures which adorn the Strand façade of the new buildings of the Association ought to be removed. They are good and dignified sculpture, they are suitable to the building, and could only offend the sort of nasty-minded person whom it is useful in the cause of morality to offend and to keep on offending; and if the Association at the bidding of an ignorant outcry removes them it will not improve its reputation with the medical profession for pluck, for decency, or for knowledge of art. Some of the critics of these statues, fearing to be called pruriently prudish, say that they object to the statues not because they are naked but because they are ugly! In the name of common sense is a nude less harmful to public morals when made to be alluring? The outcry against these figures is so silly that there must be some reason behind it.

PERSISTENT HÆMATURIA FROM VARICOSE VEINS OF A RENAL PAPILLA.

IN the *Boston Medical and Surgical Journal* of May 21st Dr. W. F. Whitney has reported a case of hæmaturia due to a very rare cause—varicose veins of a renal papilla. A middle-aged man was admitted into the Massachusetts General Hospital with a history of repeated attacks of hæmaturia for a considerable period. Careful examination failed to reveal the cause. Cystoscopy showed bloody urine issuing from one of the ureters. The corresponding kidney was removed. After removal it appeared to be somewhat pale but otherwise normal. However, on closer inspection the tips of one or two of the papillæ were observed to be reddened and a little spongy. They were cut out at once, hardened, and stained. On microscopic examination the venules at the tip of the papilla were seen to be dilated irregularly to twice or thrice their normal size and to be covered on their free surface with a fine film of connective tissue and a single layer of epithelium. Here and there they projected as varicose knuckles above the surface. The conditions were such that the slightest violence must have caused rupture and extravasation of blood. In many cases the lumen of the vessels was filled with finely granular detritus and occasional blood corpuscles. That hæmorrhage must have taken place here was borne out by the fact that the straight tubules contained blood corpuscles. The condition described was adequate to account for frequent and severe hæmorrhage, for an insignificant lesion will produce severe epistaxis. In this connexion it is interesting that there is an abundant vascular plexus at the apex of the normal papilla and that the vessels are separated from the surface only by a thin layer of tissue. After studying this case Dr. Whitney's attention was called to a series of cases reported by Mr. E. Hurry Fenwick under the title of "Painless Hæmaturia of Angioma or Capillary Nævus of a Renal Papilla." Dr. Whitney regards his own case as belonging to this class but considers that the condition is one of varicose venules rather than of angioma or nævus. The following is one of Mr. Fenwick's cases. A girl, aged 18 years, had suffered for five years from intermittent hæmaturia. Astringents had no effect. Bacteriological and microscopical examination showed no evidence of the nature of the disease. On one occasion dark blood was seen issuing in jets from the left ureter. As the patient became very anæmic the kidney was explored and brought out on the loin. It was healthy to sight and touch. On incising the pelvis what appeared to be a villous tumour of a papilla was seen with the electric light. A tuft of vessels surrounded the apex of a papilla. With a Volkmann's spoon the papilla and half of the pyramid were cut out. The vessels of the mucous membrane covering the papilla were markedly varicose. Mr. J. H. Targett examined the specimen and reported that there was no evidence of growth but that there was congestion of vessels with extravasation of blood and increase of the cellular stroma. The hæmaturia ceased.

THE NATIONAL ASSOCIATION FOR SUPPLYING FEMALE AID FOR THE WOMEN OF INDIA.

THE Viceroyalty of the late Earl of Dufferin was *certainly* one of the most beneficial events that our great Eastern Dependency ever experienced. But not only did the Viceroy insure by his wise statesmanship a calmful rest to the somewhat troubled waters that were existing when he took up the reins of office but he was well seconded by the able counsels of his wife. Through her instrumentality the School for the Training of Christian Indian Women as Medical Missionaries was established to work in connexion with all Protestant missionary societies. The purpose of this school was to enable them to obtain a Government diploma in medicine, surgery, and obstetrics; in it they were to be trained as nurses, compounders, and midwives, whilst at the same time they were to labour in evangelistic work amongst their patients. That such trained women were necessary was at once evident when we consider that the Indian woman is jealously guarded from the eyes of Europeans. For instance, a medical man would be expected to make a diagnosis by feeling the pulse of a patient's hand thrust through a hole in a purdah. Only female doctors having entrance to Mussulman and Hindu homes would have opportunities for carrying enlightenment on religious subjects to mothers dominated by beliefs, creeds, and superstitions some of which were cruel and most of which were grotesque. To set aside these ancient superstitions was a work of enormous magnitude when we consider the innate conservatism of the Indian people, and the only hope of doing so was by the founding of a school such as the Countess of Dufferin originated. Each succeeding year since its inception has shown increasingly gratifying results. The last report, for instance, for the year 1907 demonstrates that at the Memorial Hospital of the school situated at Ludhiana there were 1188 in-patients, 16,517 out-patients, and a total of attendances of 52,374, or more than 1000 a week. The total operations were 583. There are 100 beds and at the present moment 43 students are undergoing training. In addition, however, to the hospital at Ludhiana the report shows the great work that has been accomplished by the numerous Dufferin hospitals throughout the length and breadth of India, not only the use of decomposed preparations. Dr. Biberfeld tested a preparation consisting of three parts of the dextrorotatory modification and one part of the lævorotatory on the kymograph and found that it was equal in activity to synthetic suprarenin. Further interest is lent to the controversy by an article by Dr. Arthur R. Cushny[2] supporting Professor Dixon. He took the natural base, the synthetic base, and the base referred to by Dr. Biberfeld, and found by experiments on dogs that their relative strengths bore the relation 4:2:1. Hence the dextro modification would appear to be inert as regards effect on the blood pressure, and the synthetic base, consisting of equal parts of the optical isomerides, has only one-half the power of the natural substance. Dr. Cushny denies that Professor's Dixon's solutions were decomposed and suggests that Dr. Biberfeld's divergent results may be explained by his unfortunate choice of the rabbit, as this animal rapidly acquires a tolerance for the drug.

INDIAN MEDICAL SERVICE: THE ANNUAL DINNER.

THE annual dinner of the Indian Medical Service was held on Thursday, June 18th, at the Gaiety Restaurant, Surgeon-General A. M. Branfoot, C.I.E., being in the chair. The principal guest was Lord Morley of Blackburn, Secretary of State for India. The following members of the Service were present:—*Surgeon-Generals*: G. Bainbridge, W. R. Browne, C.I.E., J. Cleghorn, C.S.I., A. Eteson, C.B., J. P. Greany, G. Hay, L. D. Spencer, C.B., and P. W. Sutherland. *Colonels*: S. H. Browne, C.I.E., C. W. Carr-Calthrop, W. E. Cates, D. E. Hughes, C. H. Joubert de la Ferté, W. G. King, C.I.E., M. D. Moriarty, W. O'Hara, P. A. Weir, T. J. H. Wilkins, and W. A. S. Wynne. *Lieutenant-Colonels*: C. Adams, R. Bonstead, E. H. Brown, Sir R. Havelock Charles, K.C.V.O., W. Coates, R. Davis, H. P. Dimmock, A. Duncan, T. E. Dyson, W. H. W. Elliot, L. G. Fischer, P. J. Freyer, W. Gray, B. B. Grayfoot, H. N. V. Harington, P. Hehir, H. Hendley, R. A. K. Holmes, E. R. Johnson, Sir A. S. Lethbridge, K.C.S.I., A. W. D. Leahy, S. Little, J. Lloyd Jones, C. G. W. Lowdell, D. P. MacDonald, F. P. Maynard, J. Moorhead, T. H. Pope, K. Prasad, J. Reid, F. C. Reeves, T. G. Skardon, G. S. Thomson, W. H. Thornhill, J. F. Tuohy, G. Waters, W. R. Woolbert, and F. W. Wright. *Majors*: A. R. S. Anderson, H. S. Caldwell, A. Gwyther, P. B. Haig, J. G. Hulbert, J. Jackson, C. H. James, E. A. R. Newman, F. R. Ozzard, W. J. Prideaux, and H. Smith. *Captains*: W. R. Battye, H. M. Brown, J. K. S. Fleming, R. B. B. Foster, R. W. Knox, J. M. D. Megaw, W. O'S. Murphy, A. E. H. Pinch, J. N. Walker, E. L. Ward, and J. J. Urwin. The other guests present were Sir R. Douglas Powell, Bart., K.C.V.O., President of the Royal College of Physicians of London; Sir Thomas Barlow, Bart., K.C.V.O.; Sir William S. Church, Bart., K.C.B., President of the Royal Society of Medicine; Lieutenant-General Sir O'Moore Creagh, V.C., K.C.B.; Colonel D. Wardrop, Commandant, Royal Army Medical College, Millbank; Mr. Austin Low; the Editor of the *British Medical Journal*; and Dr. S. Squire Sprigge. As usual at this pleasant dinner there were no speeches, Lord Morley merely acknowledging the obvious pleasure of the diners at his presence by a few words. A selection of songs rendered with grace and spirit by Miss Clara Evelyn well deserved the warm appreciation that was expressed by the diners.

THE Earl of Crewe will unveil the statue of Her Majesty Queen Alexandra at the London Hospital on Friday, July 10th, at 4 P.M., on the occasion of the prize distribution to the students and probationers of the Medical College.

WE much regret to announce the death at the early age of 38 years of Dr. Bertram Abrahams, assistant physician to the Westminster Hospital.

THE RELATIONSHIP OF THE SO-CALLED FAMILY DISEASES TO A PREMATURE PHYSIOLOGICAL SENESCENCE LOCALISED TO CERTAIN ORGANIC SYSTEMS,

AND CONSIDERED WITH SPECIAL REFERENCE TO THE NERVOUS SYSTEM.[1]

BY F. RAYMOND, M.D.,

MEMBER OF THE PARIS ACADEMY OF MEDICINE; PROFESSOR OF CLINIC OF NERVOUS DISEASES IN THE FACULTY OF MEDICINE; PHYSICIAN TO "LA SALPÊTRIÈRE"; PRESIDENT OF THE FRENCH SECTION OF THE "ENTENTE CORDIALE MÉDICALE."

[Dr. Raymond, after paying a graceful tribute to the address delivered on Feb. 18th last in the theatre of the Faculty of Medicine of the University of Paris by Sir Dyce Duckworth, President of the English section of the "Entente Cordiale Médicale," proceeded to lecture, in French, upon the family diseases of the nervous system and the part played by heredity in these diseases. He said:]

The so-called family diseases are most interesting. They form a class of very peculiar maladies, a nosological group as important from its particular characters as from the considerable development it is deservedly attaining in pathology. Whether you consider their anatomy or their pathological physiology, their symptoms or their course, they stand out with such strong and personal features that they cannot be mistaken for any other disease. No trauma, *no infection, no intoxication, no diathesis gives rise to them.* From beginning to end they follow an inevitable course, as inevitable as the "Fatum" of the Ancients. To become the victims of these diseases the subjects have only to be born of the same parents and reach the age marked out by Fate. Family diseases, unlike so many others, are not the expression of a struggle waged by the system against a morbific agent (and the word struggle implies possible victory). They are the consequence of the original constitution of certain *nerve tracts or cells* and *so they* have sometimes been called "Evolution Diseases." As a matter of fact, they can hardly be termed "Diseases," for they are really *organic types abnormal from their very origin.*

I purposely say "family diseases" and not "hereditary diseases." The latter term includes too many complaints and, moreover, pathological heredity is one with normal heredity: it is present in all sick persons—I was about to say in all men. We all know its enormous influence on the development of nervous diseases; its characteristic feature is its great dissimilarity. Moreover, an efficient morbific cause is always found working with it. Not so with the family diseases; they are exclusively created by the parents, by the ancestors, and they develop quite apart from any external influence. Clinically it is easy to realise the absence of any external influence when we see several brothers and sisters who have lived in widely different conditions developing at the same age one same disease which is inevitable and progressive and due to pathological changes which are not those of defence or inflammation. Are these diseases always, strictly speaking, "family diseases," that is to say, are they always repeated in several members of the same family? By no means. They are often met with as isolated cases, and it is by their own symptoms that they can be recognised.

Another general remark which must not be overlooked in connexion with these diseases is that the different clinical types which constitute them are not found to be identically the same in all cases. It seems as if each family had its own way of working out the same family disease, just as if the fact of developing in different families caused each dermoid cysts is generally easy, though they may on the one hand be confused with teratomata and on the other with sebaceous cysts. The distinction in doubtful cases will depend on the nature of the sac wall and of the contents. In the present issue of THE LANCET is printed an account by Mr. P. Maynard Heath of a dermoid occurring behind the ear, a somewhat rare situation.

---

[1] An address delivered before the Royal College of Physicians of London on June 22nd, 1908.

THE EYES OF EPILEPTICS.

THE results of some observations made upon the eyes of epileptics between the attacks, undertaken by Dr. A. Rodiet of the St. Yon Asylum, Dr. P. Pansier of Montpellier, and M. F. Cans of the Asylum of Mondevergues, have been published in recent numbers of the *Recueil d'Ophtalmologie*. These observers, who have had large opportunities of investigation, find that slight dilatation of the pupil may be noticed during the period of depression that follows the paroxysm, and that whilst the ordinary reflex phenomena take place their character is often disturbed, as, for example, by hippus and by paradoxal reflex. In addition injection of the conjunctiva accompanied by anæsthesia or hyperæsthesia may be observed which is not only very well marked during the phase of clonic spasms but remains for some time after. The fundus of the eyes presents a certain degree of hyperæmia which lasts for an hour or two if the case is slight, but if severe may persist for 12 hours. In the intervals of the attacks the papilla is pale and the retinal vessels are small, probably indicating general anæmia. In epileptics of old standing, or presenting very serious attacks, neuritic troubles or grey optic atrophy may be seen. Not infrequently, if the state of conjunctival and temporary retinal congestion recurs at short intervals, a permanent condition of hyperæmia is induced, so that with pallor of the papilla there is great passive congestion of the retinal vessels. Occasionally the choroid and retina show well-marked pigmentation highly suggestive of hereditary syphilis. There may also be irregular contraction of the field of vision not amounting to hemianopia especially noticeable just after the fits.

INJURY TO VEGETATION AND CATTLE DUE TO SMELTER WASTES.

THE United States Department of Agriculture has recently issued a bulletin[1] by Mr. J. K. Haywood dealing with the injury that is sustained by vegetable and animal life in the vicinity of copper smelting works, owing to the smelter wastes. The investigation, which was conducted at Anaconda, Montana, is of interest to sanitary officials as well as to agriculturists. The principal waste products are sulphur dioxide, with a little sulphur trioxide, arsenic, copper, lead, and zinc. Experiments are recorded showing the injurious action of sulphur fumes on vegetable life. The arsenic is given off in the fumes of the smelter in a volatile form and is deposited upon the surrounding lands and crops where cattle are reared. A comparatively large amount of copper in suspension, and to a less degree in solution, is found in the "tailings" from the water concentrations and in the drainings from the "dump heaps," which eventually pollute adjacent streams. Finely-divided particles of flue dust, containing sufficient quantities of copper, lead, and zinc to injure vegetation, were found in the atmosphere at considerable distances from the smelters. It was found that the vegetation around a smelter was greatly injured by the sulphurous gases to distances extending 20 miles north, eight miles south, six miles east, and 15 miles west, and less severe injury probably extended for a considerable distance beyond these limits. Arsenic was found in quantities sufficiently large to poison cattle in samples of forage crops gathered at varying distances up to ten miles from the smelter and in samples of the soil collected at a distance of eight miles. These results are of great importance to medical officers of health and sanitary boards, as conditions which injuriously affect vegetable life and cattle are prejudicial also to man, not only by the pollution of streams and the air but by introducing a danger of epidemic arsenical poisoning through the agency of cattle fed on contaminated pastures and dry forage.

THE CORONERS' SOCIETY.

THE annual banquet of the Coroners' Society of England and Wales was held at the Holborn Restaurant on June 18th. The chair was taken by the President of the society, Mr. Isaac Bradley, J.P., coroner for Birmingham. The banquet, which was well attended by members of the society and guests, was very successful. After the usual loyal toast had been proposed by the chairman, that of "Imperial and Local Government" was proposed by Mr. Christophers, coroner for Warwickshire, and responded to by Mr. J. T. Middlemore, M.P. for the Northern Division of Birmingham, on behalf of Imperial government, and by Mr. R. A. Robinson, chairman of the London County Council, on behalf of local government. The toast of "The Coroners' Society" was proposed by Mr. C. E. Troup, C.B., of the Home Office, who referred to the work of the society and the valuable character of its reports. The reply was made by the chairman in an eloquent speech, delivered in admirable style, referring to the duties and responsibilities and anxieties of the coroner's office. The health of the guests was proposed by Mr. Troutbeck, coroner for Westminster, and responded to by Mr. George Crisp Whiteley, President of the Society of Justices' Clerks, and by Mr. W. W. Kelland, the chairman of the Middlesex county council. The toast of "The Officers of the Society" was proposed by Mr. C. L. Rothera, coroner for Nottingham, who referred to the excellent work of the honorary secretary, Mr. Walter Schröder, and the honorary treasurer, Mr. G. Perceval Wyatt. Mr. Schröder responded and alluded to the help which he obtained from the members of the council. During the evening a pleasing entertainment was provided under the direction of Mr. Arthur Winter.

SYNTHETIC SUPRARENIN.

Dr. F. Stolz, the originator of synthetic suprarenin, in the *Pharmaceutical Journal* of May 16th takes exception to Professor W. E. Dixon's conclusion[1] that the synthetic substance is less active than the natural suprarenin. He states that the results of investigations by a large number of clinicians and pharmacologists have furnished proof that the synthetic article is the more active. Dr. Hans Meyer of the Pharmacological Institute, Vienna, showed that both substances are identical in their influence on blood pressure and vascular contraction, in their anæmic and mydriatic action, and in the production of diuresis and glycosuria. He quotes the statement of Dr. Barhem of Bonn University that "synthetic suprarenin is not inferior to the natural in practice," and states that these conclusions have been confirmed by Dr. Hans Hoffmann of Leipsic, Professor Braun of Zwickau, and many others. In the same number of the *Pharmaceutical Journal* Dr. J. Biberfeld of the Pharmacological Institute, Breslau, publishes recent confirmatory experiments on rabbits showing similar results from both substances in raising the blood pressure. He combats the suggestion of Professor Dixon that the lævo-rotatory portion alone of the synthetic suprarenin is active, whilst the dextro-rotatory portion is wholly inactive, and attributes Professor Dixon's results to

[1] Bulletin No. 113, Bureau of Chemistry, United States Department of Agriculture, pp. 40, 1908.

[1] THE LANCET, May 23rd, 1908, p. 1502.

The *course* of the disease is the most important point. The onset is slow and insidious, so that it is impossible to state accurately at which moment the trouble has begun. The course is always progressive. There is never any retrocession; never does a symptom fade or disappear when once it has appeared. Sometimes the course is hastened under the influence of certain causes (nearly always toxic or infectious). But the rule is an imperceptible and continuous progression, running on very slowly and very smoothly till the complete disappearance of the affected system. The disease may not necessarily prove fatal, the affected system may not be indispensable to life, or else its function may be carried on by another system so that death will not come about without the interference of some other disease. Death is not, therefore, the direct, immediate, and fatal outcome of family diseases proper.

It now remains for us to see how the family diseases develop—what is their pathogeny? What place should they occupy in a classification of diseases? The problem is not only of a speculative interest; it has also a great practical bearing.

When describing the inevitable course of family diseases I made no reservation, the patient is doomed from the very instant of his conception as soon as spermatozoon and ovum have united. Now this we can prevent by forbidding marriage to those individuals who bear an hereditary stigma. We must never forget that a physician must try to *prevent* at least as much as *cure.* Moreover, prevention is easier than cure. From the standpoint of prevention it may be therefore of the highest practical importance to know the circumstances which give rise to family diseases.

In the first place we must inquire into the etiological factors such as we find them in the detailed reports on which has been built the history of these diseases. Unfortunately, at the present time we can trace but their outline. The problem may, however, be somewhat simplified by the following considerations which it seems to me have not sufficiently engaged the attention of observers hitherto.

The perfect development of a germ supposes in the first place the existence in that germ of its own attributes. In the human species the germ arises from the union of the spermatozoon with the ovum, and these must necessarily possess certain qualities for the germ to be able to develop. Further conditions are also necessary; thus a favourable medium is particularly indispensable, for one cannot separate the germ from the medium in which it is about to develop.

In relation to family nervous diseases the plain facts are as follows. An organic system—the nervous system—comes into life, develops itself, performs its functions, then fades away, dies, and disappears at a far earlier period than the other systems of the body; we see it atrophy, lose its functions, and undergo sclerotic changes long before the death of the individual. The mechanism of this isolated and premature disappearance of an organic system is rather obscure. Is there in each cell a certain dose of energy which gradually gets exhausted until it entirely disappears? This is a somewhat vague and philosophical conception. At any rate, it is no explanation to us physicians so long as the word energy does not apply to something tangible and well defined. Is there, on the contrary, a poisoning of the nerve cells through some modification in their medium—as, for example, the formation of a special cytolysin? Again, are the sclerotic changes brought about by an accumulation of waste products the results of cell activity?

This last hypothesis is rather tempting, for it enables us to understand why it is that the onset of the disease takes place at about the same age in the several members of a same family—that is to say, in individuals whose cells have the same chemical characters and the same medium. We can understand, then, that fibrous degeneration appears at the same moment in the members of one family just like fermentation of yeast cells stops in a given medium at the end of a certain time always the same for the same kind of yeast, whereas by altering the medium the period of senescence of the yeast is changed. Now the patients in question represent the same primary germ, the same maternal medium, and most likely the same individual medium.

As an example of the duration and family character of an organ or function nothing could be more striking and instructive than the result of some careful observations I have just made at the Salpêtrière on the duration of genital life in certain families. I have found 12 families who have been able to give me accurate information as to the time when menstruation appeared and ceased either in the mother and daughter, or in several sisters, or at the same time in the mother and in several daughters. The duration of genital life as characterised by menstruation is very variable. We have found it to last from 21 to 42 years with all the intermediate figures. In those 12 families the duration has proved the same in mother and daughter with a possible difference of one year.

Let us now return to the family diseases of the nervous system and their pathogeny. The nerve cell naturally takes its share of the qualities of the primary germ cell resulting from the union of the spermatozoon with the ovum. Now one or other or both of those cells may undergo some influence which may modify their normal characters simply because the father and mother suffer from a pathological disturbance of their tissues and body fluids. Now I insist on the fact that up to the very time of conception the modifications of the parent cells may have a very decided influence on the daughter-call, the germ. To bring about a change in the spermatozoon or ovum it is not necessary for the father or mother to suffer from the slow and prolonged action of a chronic disease; remember the baneful consequences when conception takes place when one of the genitors is in a condition of drunkenness. Apart, however, from inebriety—which may affect several members of the same family—we can imagine similar results arising from the use of other exciting poisons such as cantharides or even from any other exciting cause. It has been said that suggestion may cause certain disturbances in the development of the fœtus, a great mental shock or even the memory of such a shock may perturb the parent cell. Now if we consider the action of drugs have we not good reason to be struck with the truly magical effects of mercurial treatment on syphilitics before conception? Take a syphilitic man. He marries but conceives no children, or else his wife cannot bring to term a single pregnancy. We give a few grains of mercury and conception takes place, the child is born at term, and his development is normal. In view of this fact is it not wonderful that in our daily life there should be such a uniformity of our inner medium that spermatozoa and ova are only exceptionally modified and deviated from the normal type. We are bound to realise that the variations of our inner medium are of the slightest and we may remark also that by the union of the two cells of opposite sexes there takes place as it were a levelling of defects so that the average type of the species is maintained. Here, again, pathology inforces its laws. It is necessary that the pathological peculiarities of the germs which go to form the embryo be of a different kind so as to neutralise each other. If the peculiarities are of the same nature—synergetic—they will add themselves or even multiply and the new being will be not of the normal but of a pathological type.

However great the influence of synergy or opposition of parental defects or stigmata this influence is reduced to nought when the stigmata of one parent are marked enough to remain predominant. One parent may in that case unite with different partners and reproduce every time the same pathological type. And so in a careful etiological inquiry, in case of a second marriage, we are led to examine whether the children born of the second union present the same morbid peculiarities as those born of the first.

This is not all. After the union of the spermatozoon with the ovum the evolution of the future being is far from settled. The new germ cell arising from the fusion of the two parental cells must now multiply. This is only possible under special conditions of nutrition, temperature, and surroundings. If the conditions differ too widely from what they should be the cell will perish and will give rise to no living being. If the conditions are moderately different a new being will come into existence but it will be an abnormal one. In man, of course, the maternal medium is necessary for the development of the ovum. Anything that may perturb the maternal medium may therefore exercise an effect on the developing ovum. It is, therefore, impossible to exaggerate the necessity of placing the mother in as healthy conditions as possible.

Now it so happens that pregnancy exercises a marked disturbing influence on the organic functions. This influence on the organic functions may differ in intensity and in nature. Here, again, is a subject for important researches to be made amongst mothers who have borne children suffering from family diseases. The child being born will now develop in the outer medium; it will have to withstand external influences, such as defective airing or clothing, and, morbid type to receive a somewhat different stamp. And thus it is that the classification of family nervous diseases is difficult. Every year, as it were, new diseases spring into existence because authors describe too often as a special disease what is in reality a peculiar form of disease already well recognised.

[Dr. Raymond illustrated this point by considering progressive muscular atrophy, which, after being described by Duchesne of Boulogne as a single disease, was differentiated by subsequent observers into several varieties, until the unity of its myelopathic and myopathic types was again proclaimed by himself (Dr. Raymond), his opinion being confirmed by the description of an intermediate family type of the disease by Werdnigg and Hoffman. He proceeded:]

We have, then, a series of well-defined syndromes, some of which constitute obviously family diseases, others that we consider as such by reason of their clinical similarity with the members of the first group. The two groups unite to form one class which bears the name of progressive muscular atrophy.

The same demonstration could be made in regard to other varieties of family diseases, especially the group of "Hereditary Ataxias." In my lectures on Friedreich's disease I have demonstrated the existence of hybrid forms of hereditary ataxia. These forms have so increased in number that the pure type which was first described is now the exception rather than the rule. As a matter of fact, there is no well marked boundary between the two extreme types of hereditary ataxia—the spinal form and the cerebellar form. Friedreich's disease and the cerebellar heredo-ataxia of Pierre Marie, with the intermediate types, have as a common feature the changes in the cerebellar system both in its afferent and efferent paths, and in my lectures of 1905 I proposed the following classification:—

A.—A *spinal form*, with loss of reflexes, scoliosis, and club-foot added to the common syndrome. This would be the *Friedreich type*.

B.—A *cerebellar form*, with atrophy of the optic nerves, vertigo, mental disturbances, added to the common syndrome forming the *Marie type*.

C.—A *bulbar form*, with vomiting, dyspnœa, and cardiac arrhythmia.

D.—A *bulbo pontine form* characterised by auditory disturbances.

E.—A *generalised form*, as in Menzel's case.

These are all different types, but they are all linked together by the *common cerebellar syndrome.* This same common link has been found in those types described by Pauly and Nonne, by Lorrain, and which are intermediate between family ataxia and the spastic paraplegia of Strümpell. It also appears in the recent cases published by Mademoiselle Pesker in her Thesis and where the cerebellar syndrome is associated at the same time with symptoms of mental failing with spastic paraplegia, the anatomical basis of this condition being well-marked hypoplasia of the whole cerebro-spinal axis without sclerosis. In all these cases disease is the direct outcome of heredity, and this fact should be borne in mind when attempting a nosological classification.

Family diseases can, however, be considered from a higher and more general standpoint. I use the word *general* advisedly, for this question is by no means confined to the nervous system.

I have no intention of making a lengthy digression in the domain of general medical pathology. I may be allowed, however, to recall the excellent work that has been done of late years on family diseases of the digestive system (merycismus, periodical vomiting), of the liver and bile ducts (as, for example, family cholæmia, so well described by Gilbert and Lereboullet), of the kidney (Charrin and Delamarre, Castaigne and Rathery), of the circulatory apparatus, of the skin, the organs of sense, the blood (hæmophilia), the bones (achondroplasia, cleido-cranial dysostosis, &c.).

It is most important to recognise accurately the family character of a disease, whatever be the disease and its localisation. By this I mean that we should not give the name of "family diseases" indiscriminately to all congenital or hereditary diseases. Thus we separate from the group of family diseases those maladies where heredity manifests itself by the transmission of some infection, such as syphilis or tuberculosis. Several children born of a syphilitic father may be afflicted with the symptoms of hereditary syphilis without our considering this in the least as a "family disease." If, however, the children exhibit dystrophic stigmata the distinction is more difficult. These remarks about syphilis apply equally well to tuberculosis, diabetes, gout, intoxications such as lead-poisoning, or alcoholism.

It becomes very difficult to apply the qualification of family disease when in a family heredity creates a *locus minoris resistentiæ*, which is to be found in all its members. It is in this sense that Gilbert and Lereboullet understand the family character of cholæmia. In the patients to whom the authors' description applies there is a special predisposition to infection; hence at the first opportunity a morbid condition arises in the bile-ducts.

I fully recognise the analogy between the pathogeny of those diseases and that of the family diseases as I understand them. But we must bear in mind that in those conditions described by Gilbert and Lereboullet the disease is not fatal; it does not develop at the same age in all the members of the same family; finally, it depends necessarily on the intervention of some external agent, microbe, poison, or toxin. Now all these characters are essentially different from those ascribed to family diseases proper. Under this heading I place only those diseases which affect in an identical form several children in the same generation, which make their appearance at the same age in all of them, and which originate without the intervention of any morbific agent whether extrinsic or intrinsic.

Of the three fundamental characters just mentioned the first two may be wanting, as there are isolated and aberrant cases; these are all the more difficult to identify that the most remarkable peculiarity of family diseases is a great variableness in the symptoms. We must not expect to find the same type everywhere, each family has its own. Even the best known of these diseases—as, for example, Friedreich's hereditary ataxia—does not always appear with the same features. The absence of all known efficient cause is therefore the principal character of family diseases. Nevertheless, the morbid anatomy, the symptoms, the course, are sufficiently peculiar to identify the *nervous* family diseases, the only ones I have in view here.

The *morbid anatomy* is characterised not by localised degeneration to one or other of the fibre groups or cell masses but by strict localisation to one or several systems. No inflammatory products are found, whether nodular or in streaks and extending to the several tissues of the one same region. Macroscopically, we simply notice the disappearance of certain parts which constitute, as we know, one functional whole. Microscopically, we only meet with simple atrophy of the nobler elements with hypertrophy of the interstitial tissue. In some cases this hypertrophy is limited to the replacement tissue; in other cases, such as pseudo-hypertrophic myopathy or in the interstitial neuritis of Déjerine and Sottaz, it reaches an abnormal development. But in all those cases one very important fact is noticed and that is the absence of any inflammatory reaction. The system has not to repulse an attack from the outer world or from the depths of its own being. There is no trace of a struggle and therefore no evidence of defence. The lesion consists simply in the disappearance of a system of cells or fibres which dissolve, as it were, without leaving a trace. Connective tissue growth then occurs and takes the place of the cellular system that has disappeared, but this is only to fill the void. This process, therefore, is very different from that which modern conceptions ascribe to diseases. These are likened to a real battle with its hand-to-hand struggles, its defenders and assailants gallantly fighting against one another and destroying one another amid much havoc. Again, the process is very different from the less boisterous but none the less earnest attack of poisons or toxins, causing our cells to decay and modifying our body fluids. Nor can it be compared to the traumatic changes such as are found in the neighbourhood of a tumour or of a hæmorrhagic area, nor to the massive necrosis of ischæmia, whether due to an embolus or to arterial stenosis.

The *symptoms* of the family nervous diseases depend entirely on the physiological functions of the tracts or cells that are doomed and are disappearing gradually. Any part of the neuro-muscular system may be involved. We must remember, however, that even when the morbid changes are well limited the functional disturbances point nevertheless to an involvement of the whole neuro-muscular system. The proof of this is in the frequency of the mental syndrome. The sphincters, however, remain as a rule untouched until the very last period of the disease.

boxes and instruments the extension of this practice cannot be regarded as anything in excess of what is urgently demanded in the interest of the public. As these places are under the control of the Postmaster-General local authorities have no jurisdiction; it is therefore incumbent on the Post Office to see that they are properly constructed, regularly and frequently inspected, disinfected, and kept thoroughly clean.

THE RESEARCH DEFENCE SOCIETY.

THE inaugural meeting of the Research Defence Society was held at 20, Hanover-square, London, on June 19th, the President of the society, Lord Cromer, being in the chair. The report of the committee stated that the members of the society already numbered over 1300.

Lord CROMER then delivered the following address: When I was invited to become the President of the Research Defence Society I experienced a feeling of some surprise. Most of my life has been passed in endeavouring to steer a straight course through the bewildering shoals and quicksands of Oriental administration and diplomacy. Work of this sort, though it may, perhaps, under a somewhat strained interpretation of the word be designated as an art, can scarcely be said to rise to the dignity of a science. I suggested, therefore, that the choice of a president of higher scientific attainments than myself would be preferable. I was then informed that the absence of scientific knowledge, which I regarded as a disqualification, was, in the eyes of the promoters of this society, my principal merit. On reflection, I understood that this view was not quite so paradoxical as might at first sight appear. The men of science wished to show that they had the support of those who could lay no claim to special scientific knowledge. The humane men who are constantly accused of wanton cruelty to animals wished to show that they enjoyed the sympathy of those who had taken an active part in the prevention of that cruelty. From the latter point of view I could, I am proud to say, lay claim to some qualification, for no part of my Egyptian work interested me more than the long, and I may add fairly successful, campaign against cruelty to animals in that country, which was undertaken by the society of which I was for many years President. Gentlemen, I do not merely hold that there is nothing inconsistent between an absolute detestation of wanton cruelty to animals and approval of experiments on living creatures having for their object the relief of suffering to both human beings and dumb animals. I go further than this: I maintain that the one attitude is the necessary consequence and corollary of the other, and that if the necessity of the experiments may, as I hold, be justified by any good and sufficient reasons, their execution should be, so far as is possible, watched and controlled by a body of men who would shrink with horror from anything indicating indifference or callousness to the wanton infliction of pain. If I thought that the charge of indifference or callousness could be justified the case would be very different. I do not hesitate to say that the Research Defence Society would then have to look out for another President. It is because I am convinced that the charge cannot be justified that I am here. What are the main grounds on which vivisection can be defended? They are twofold. In the first place it has to be shown that experiments on living animals have already produced invaluable results and may produce results still more invaluable. In the second place it has to be shown that the experiments are conducted in such a manner as to minimise, if not altogether to obviate, suffering of any kind. I hold that both of these propositions can be proved up to the hilt. There are, I am aware, a certain number of persons who think that it is not under any circumstances justifiable to destroy animal life. With those who hold this extreme view we must, I fear, agree to differ. The full application of their theory would, as it appears to me, carry us to some very strange and practically impossible conclusions. I will not attempt to argue this point. I need only say that the civilised world in general is not prepared to accept this view. But with others who do not go to these lengths the case is different. Of these I should like to say that I respect their motives and although I am not always able to accept the accuracy of their facts or to concur in their conclusions, I fully sympathise with the objects which they have in view. It is on this account that I will not reply in any unfriendly spirit to the various communications, many of them couched in somewhat violent and unreasonable language, that I have recently received on this subject. Now, first, as to the utility of vivisection I must of course leave the detailed examination of this question to those possessed of special knowledge, but it requires no special knowledge to be convinced that well-nigh every advance in medical science since Harvey discovered the circulation has been, directly or indirectly, the result of experiments on living animals. Let me give one or two instances. One of the greatest discoveries of modern times is that the transmission of malaria is effected by mosquitoes. In the words of a very eminent authority, this discovery "is going to make the tropics habitable." I have myself seen enough to enable me to judge of the enormous value of this discovery. Fever has almost entirely disappeared from the town of Ismailia on the Suez Canal, which was at one time becoming well-nigh uninhabitable owing to the prevalence of this disease. It will, I know, be said that this discovery was not due to vivisection; but listen to what so high an authority as Professor W. Osler, the Regius professor of medicine at Oxford, says on this point. He was asked by the Royal Commission now sitting whether the discovery would have been made had it not been for previous experiments on animals. "Never," was the reply. "The men who made these investigations spent their lives in the laboratories and their whole work has been based on experimentation on animals." Malta fever, as to which I need not give the details, is another case in point. Experiments on monkeys led to the discovery of the cause of the disease. As to the actual saving of life, the advantages which have been obtained by vivisection can be proved to demonstration. Take the case of diphtheria, which has given rise to much discussion. The figures, if they are fairly used, are conclusive. The percentage of fatal cases in the Metropolitan Asylums Board's Hospitals has sunk from 28 in the period which preceded the introduction of the antitoxin treatment to 2·8. Similar facts might be adduced as regards rabies. Need I dwell on the argument that no cure for cancer has yet been discovered? Scarcely. I am not aware that it was ever held to be a reproach to Sir Charles Wheatstone, the father of modern telegraphy, that he failed to anticipate the discovery of Marconi. It is safe to predict that if ever a cure for cancer is found the discovery will be due not to observation, but to the experimental method. I now turn to the other branch of the question, I mean the methods adopted in conducting the experiments. Several causes have contributed to lead to much misapprehension on this subject. In the first place, some isolated case is often taken and presented to the public with a variety of harrowing and revolting details. As regards these isolated cases I have to observe that in the first place the facts have to be accepted with the utmost reserve. On examination they very frequently turn out to be either greatly exaggerated or wholly imaginary. In the second place, it is an old and well-recognised maxim that hard cases make bad law. Of course, I fully recognise that if even in a single case wanton cruelty could be shown, the subject is one which calls for careful inquiry, with a view, if possible, to preventing the occurrence of any such event in the future; but I must demur to the conclusion that a few exceptional and perhaps accidental cases are sufficient to condemn a whole system which, as I have already stated, can be proved to be productive of the utmost good to the human race and to animals in general. Then a very large number of these cases which are constantly presented to the public appear, so far as I can understand, to have occurred in somewhat a remote past, and I daresay that in the past some real cases of cruelty may be cited. But we now have to deal not with the history of vivisection, but with the operation of the system since the Act of 1876 was passed. Then, a great deal of misapprehension exists as to the extent to which vivisection is carried on. According to the last figures I have seen, which come down to the end of the year 1907, about 73,000 experiments were made in that year. But of these no less than 96½ per cent. were inoculations, hypodermic injections, and so on—that is to say, they did not involve operations of any kind, and, in a large majority of cases, were altogether painless. In the remaining 3½ per cent. the operation was always carried on under anæsthetics. The testimony of Professor G. D. Thane, the Government Inspector, is conclusive on this latter point. In his evidence before the Royal Commission he said that animals were always effectively anæsthetised. I should like also to draw above all, faulty nourishment, and we all know what extraordinary food is given sometimes to children in certain classes of society.

An inquiry into the causes of family diseases is a most difficult enterprise, for it must go carefully into the circumstances that may have modified the health of the parents before they conceived; it must include the question of opposition or synergy of hereditary taints; it must find out the possible disturbances of the maternal medium during pregnancy; it must examine the hygiene of the children, &c. All those points must be minutely investigated if we are to get at the truth. When all those causes have been brought to light we must go still deeper into the subject. We must try to find out why a given part of the system is attacked in preference to another, why in one case the muscles are involved, in another the posterior or the lateral columns of the cord, in another the cerebellum, in another the optic nerves. Then another problem remains to be solved: Why do the cells disappear at a certain age and not at another?

If we consider the nervous system we see that despite all the precautions taken by nature to place the nerve cells beyond the action of any traumatic or toxic influence they are still very fragile, for they feel the action of a few whiffs of chloroform, or a glass of alcohol, of a few centigrammes of morphine, of a few milligrammes of strychnine, or of prussic acid. Nothing is to prevent us from thinking that in the course of development there are thrown into the circulation of the individual, at certain periods of his life, substances that are very toxic to his nerve cells, as, for example, those cytolysins the existence of which we are just beginning to suspect. I am alluding now to the most powerful of the internal secretions, as, for example, those that are connected with the development of the genital system; the influence of these is such that puberty or castration brings about a veritable revolution in the system. Now, is it not chiefly at the time of puberty that the family diseases of the nervous system become manifest? Whether they be brought about in this way or by other means, heredity governs their etiology.

In my lectures on Heredity (1894) I have shown that family diseases represent veritable degeneration-stigmata in the race. Sachs, comparing between them all the family nervous diseases and considering them as caused by an arrest in the development of the centres (brain or cord) in one of their constituent parts, has defended the same opinion. That is why I think that for the purposes of a general classification these diseases should be grouped under the following heading: "Premature Physiological Senescence of Certain Organic Systems." On one hand one often sees, as I have already remarked, isolated and aberrant cases of these family diseases; on the other hand there are certain diseases which we never meet as family diseases or exceptionally so; such are "myelopathy," amyotrophic lateral sclerosis, &c.

This physiological senescence is quite independent of any external factor; its date of onset varies with different subjects. It may be premature; that is, it may manifest itself at a period of life which is not that of normal senescence of the individual. I do not think this process is limited to the large group of family diseases of the nervous system nor even to that of family and hereditary diseases considered as a whole. I am convinced that this is a very far-reaching process which deserves to be placed on a par with intoxication and infection, the two factors which nowadays govern medical pathology.

Duclaux has rightly said of heredity that it is the great force which governs the world. To us physicians morbid heredity should be as a breviary always open in front of us to instruct us with all possible certainty as to the prospects of a given case as regards its evolution, its termination, its possible consequences for the individual or for his descendants.

In this the country of Darwin who has worked out with such sagacity the laws of normal heredity (and those of morbid heredity are the same), I need not insist on this fact that the stigmata or defects of the parents or of the ancestors are transmitted, weakened or strengthened, to the descendants. This pathological heredity, however, is not necessarily fatal. By proper measures we can prevent its consequences all the more effectively that we have penetrated more deeply in the intimate process of degeneration especially in its relationship with internal glandular secretions and with general nutrition.

Meanwhile we should be fully impressed and we should impress others with the principle that to prevent diseases due to degeneration we must only allow marriage between fit individuals who seek in marriage not wealth, but health. Physicians should never tire of repeating and spreading this truth. We must teach it to all, rich and poor, and never will compulsory education be applied to a more important subject.

[Dr. Raymond concluded his address with a commemoration of many distinguished men who have worked in the field of English neurology.]

THE PUBLIC TELEPHONE CALL OFFICE AS A FACTOR IN THE SPREAD OF DISEASE.

By Francis J. Allan, M.D. Edin., D.P.H. Cantab.,
Medical Officer of Health of the City of Westminster.

Under the above heading there appeared in The Lancet of July 27th, 1907 (p. 240), an annotation, in the course of which the two following sentences occur:—

> The telephone call station may be described, in fact, as a bacteriological box in which pathogenic and other organisms are carefully nursed.
>
> Caller after caller thus either may infect or receive infection so long as no steps are taken to purify the air within the station.

More recently, in The Lancet of March 14th, 1908, a correspondent supplied a number of specific instances of dirty call-boxes and instruments in London and many parts of the country. In two instances the mouthpieces were described as "dripping condensation from the breath of previous users," while the disgusting smell of certain of the call-boxes was such that your correspondent promptly left and went elsewhere.

The experience of all users of public telephones will doubtless be in agreement with that of your correspondent. One can scarcely picture a more suitable place for harbouring organisms of all kinds than a dark telephone call box with its stagnant air and dirty floor, the dust of which is brought in from the street and stirred up and inhaled by each fresh caller. There is, moreover, the risk that organisms of a pathogenic character may be left behind by persons suffering from such complaints as diphtheria, influenza, or consumption. In order to test the correctness of this assumption Professor Klein has been engaged in the examination of swabs taken from the mouthpieces of transmitters in public call boxes and has been good enough to hand me the results of his inquiry. In five of the six mouthpieces tested the results obtained were negative as regards tubercle, but the examination of the sixth swab revealed the presence of typical tubercle bacilli. Professor Klein's report is as follows:—

> Telephone No. —, P.O. Central. This swab had attached to it a mass of whitish-grey viscid substance. When examined in stained films it showed a number of acid fast bacilli in shape and size like tubercle bacilli. Two guinea-pigs were injected with this material—Guinea-pig A peritoneally, Guinea-pig B subcutaneously. A was killed after 23 days, and on post-mortem examination two tubercles were found in omentum; spleen enlarged, with several tubercles; liver showed a few white dots. Film specimens made of the tubercles of the omentum and of the spleen showed typical tubercle bacilli. B was killed after 27 days. P.M.—The inguinal glands much enlarged, caseous, and purulent; spleen enlarged with numerous tubercle bacilli. Result—typical tubercle.

"Thus the note of warning which you gave in the annotation to which I have already referred was fully justified." As these call-boxes are at present constructed and situated it is difficult to imagine how in the absence of regular disinfection and cleansing they can be anything but breeding grounds for germs. No doubt it is difficult to construct call-boxes which shall be efficiently ventilated and at the same time prevent outside sounds penetrating and conversation being overheard but it ought not to be an insuperable difficulty. The other condition which you mention that the boxes should be kept bacterially clean presents no difficulty. Soap and water are always available while the thorough spraying of the box and the instrument with an approved disinfectant solution once a day might be carried out with very little labour and at a trifling expense. I am given to understand that by arrangement with the Post Office the whole of the London Stock Exchange telephones, some 40 or 50 in number, are sprayed daily with a disinfectant.

In view of the infective condition of many of the public

METROPOLITAN HOSPITAL SUNDAY FUND.

THE following are some of the principal amounts received at the Mansion House, or notified directly to us as having been collected, on behalf of the Metropolitan Hospital Sunday Fund up to Tuesday evening last, when the sum paid in exceeded £10,000.

MEDICINE AND THE LAW.

Delusions not Affecting Testamentary Capacity.

Mr. Justice Bargrave Deane recently gave judgment in an action respecting the validity of a will made by Mrs. M. Govett, a lady who died in July, 1907, in her 84th year, the case being interesting on account of the clearness with which the issue was raised and as illustrating the distinction between delusions which affect the validity of a will and those which do not. The testatrix made a will in 1906 under which a nephew was made residuary legatee and which he propounded. There was no question of her testamentary capacity before Easter, 1904, and before that date, in 1900, she had made another will in favour of other relatives who put it forward, asking to have the one made in 1906 set aside. They alleged that when the second will was made Mrs. Govett was suffering from delusions, among which were the following: that people were constantly robbing her; that she saw thousands of little birds with long tails clinging to the trees in her garden; also hundreds of cats; that the illness of a neighbour had been caused by an octopus looking in at the window; that she saw curious figures come from behind a picture and various other strange animals in the garden. There was evidence that at about Easter, 1904, she had suffered from a cold and bronchitis, and also had had at that time a slight paralytic stroke, after which she was not in the same health as before, becoming gradually worse until her death. His lordship in giving judgment said that the probate court did not regard a mere delusion which did not affect the testamentary dispositions of the person suffering from it in the same light as one with regard to an individual who might be prejudiced by it in the will. There were many people in the world suffering from delusions which were not testamentary delusions and the line to be drawn between delusions and beliefs which would not be so-called was a very thin one. Some people believed things absolutely which others declared to be utter nonsense and it was necessary therefore to look carefully at the nature of the delusions alleged in any case such as that before him. In commenting on the alleged delusions of Mrs. Govett he mentioned that the eyesight of the testatrix had been said to have failed her and stated that he did not consider the delusions as described before him to be testamentary delusions. He also referred to evidence given by six nurses who at various times had attended the deceased, two of whom had had experience of mental cases, and all of whom had given evidence in favour of her testamentary capacity. These had laughed at the idea of delusions, and had used the expression that the deceased used to "fancy" this or that which he regarded as a more appropriate manner of defining her mental condition than the use of the word delusion. He also referred to evidence given by the nurses to the effect that the testatrix used to know of her own accord when the time came for paying them and used to pay them herself, insisting upon a receipt when doing so. He pronounced accordingly for the will of 1906, being of opinion that the allegation that at that time the deceased was not of testamentary capacity had not been established. He considered, however, that the question had been quite properly raised and allowed the unsuccessful parties their costs.

Evidence as to Ability to Work.

It was recently held by the Supreme Court of Nebraska (Young v. Beveridge) that the ability of a person to perform manual labour is not a matter so exclusively within the domain of medical testimony that lay witnesses, who are acquainted with the injured workman and who have opportunities of observing his ability, cannot give evidence with reference thereto. This ruling is of importance in claims under workmen's compensation legislation. The rule is said to be that the actual condition of a person's health must be established by skilled medical witnesses, but that the apparent physical condition of any person where that fact is an issue may be proved by other witnesses who have had occasion to observe such condition.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on June 18th, Mr. HENRY MORRIS, the President, being in the chair.

A report was received from the Board of Examiners in Anatomy and Physiology for the Fellowship stating that at the recent examination 114 candidates presented themselves and of these 43 passed.

A report was received from the Court of Examiners respecting candidates found qualified for the Diploma of Fellow; it stated that of the 63 candidates who presented themselves 22 were successful, three of whom had not yet attained the age of 25 years. It was resolved to issue attention to the evidence of Professor E. H. Starling, who is not only an eminent scientist, but also, I believe—though I have not the pleasure of his personal acquaintance—a man noted for his extreme sensitiveness as regards the infliction of pain to animals. Speaking before the Royal Commission he said: "Though I have been engaged in the experimental pursuit of physiology for the last 17 years, on no occasion have I ever seen pain inflicted in any experiment on a dog or cat, or, I might add, a rabbit, in a physiological laboratory in this country, and my testimony would be borne out by that of anyone engaged in experimental work in this country." It would be easy to dilate at greater length upon this subject, but I think I have said enough. Broadly speaking, I maintain that the small amount of pain and suffering caused by experiments on living animals is a price which may justifiably be paid for the enormous amount of pain and suffering which is prevented or relieved. Before many months are over I trust Lord Selby's Commission will have reported. The composition of that Commission must of necessity carry great weight with all of us. I cannot, of course, anticipate what the Commissioners will say. Whatever they may report they will give all of us who are interested in this subject an opportunity of revising our opinions by the light of the very careful inquiry which they have conducted. They may show that further restrictions are required in the interests of humanity or, on the other hand, they may show that some relaxation of restriction is necessary in the interests of science. In the meanwhile, I may conclude by saying that I esteem it a privilege to be the President of this society and to be thus closely connected with a number of very distinguished and humane men who in the interests of science and in their persistent endeavours to relieve the sufferings of humanity have exposed themselves to a great deal of very unjust obloquy.

Sir THOMAS BARLOW proposed the following motion:—

> That the Research Defence Society be and is hereby constituted to make generally known the facts about experiments on animals in this country and the regulations under which they are conducted; the immense importance of such experiments to the welfare of mankind; and the great saving of human life and health which is already due to them.

He said that as a member of the rank and file of the practising part of the medical profession he was glad of the opportunity of showing absolute sympathy with those who devoted their lives to research, and he wished to express appreciation for the invaluable help which the practising part of the medical profession derived from their brethren who performed experiments from whom they received power and strength in their work. The society had determined to come right down into the open and to put everything on the table so as to let the British public know the kind of work done, the care that was being taken, the kinds of experiments being made and their bearing on practical medicine and surgery. The society did not exist for the promotion of vivisection, it did not put forward any panacea for all the ills the world was heir to, but it had been founded for the purpose of showing to the public the true relation between experiments on animals and the scientific study of disease. The society wished to insist on the public appreciating the proper place that was taken by experimental study and investigation and its work would be to make people understand things in their true relations and see exactly what the bearings of experimental investigation were on the whole science of medicine and surgery. The history of medicine as a healing art contained much that was humbling. Advances had often been due to "happy flukes" and until recent times medicine had been to a great extent empirical, being even now overladen with useless and even dangerous empiricism. Those encumbrances could only be removed by the scientific study of the natural history of man and of the natural history of disease. He showed how the gradual acquisition of knowledge had helped forward the progress of medicine in regard to the study and treatment of fevers and he quoted it as an example of the fact that knowledge comes step by step and the immediate application of it was not always obvious. Amongst the many benefits which Mr. Joseph Chamberlain conferred when at the Colonial Office was his work in tackling the great problem of tropical disease. It was impossible for anyone who felt the solemnity of the facts he had submitted to the meeting to do anything that would hinder the progress of experimental investigation which that society had been formed to defend.

Lord ROBERT CECIL, who seconded the motion, said that he desired to ask their opponents what was the fundamental basis of their opposition to the cause defended by the society. It would, he thought, be conceded by almost everyone that for adequate cause it was lawful to take the life of animals other than man but so far as he could ascertain the contention of their opponents was that pain must not be inflicted upon animals for the benefit of human beings. If that was their case, what were the consequences in which they were landed? All sport must be instantly condemned together with the riding and driving of horses, including even the beating of disobedient dogs. On what possible grounds, too, could the imprisonment for life of animals in the Zoological Gardens be defended? It had been clearly shown that many of the most valuable of pain-saving discoveries owed their existence to vivisection, but he argued that the cause of the society did not rest on that ground. He maintained that if there was even a reasonable probability that experiments on living animals conduced to the saving of human life and the diminution of human pain then they were abundantly justified. Animals were not on the same plane as human beings and if the treating of animals with kindness involved the treatment of human beings with unkindness those who upheld such a method were guilty of a grave dereliction from morality.

The motion was put to the meeting and carried unanimously.

Mr. WALTER H. LONG, M.P., then proposed the following motion:—

> It shall be among the objects of the society to establish branch societies, and to take such steps as the committee may from time to time think advisable in the interests of science.

He said that in the course of his official life he had worked in two Government departments with which the work of the society was connected. He did not regret but was proud of what he had been able to do in those two departments in furthering the great cause of science and in helping the work of lessening suffering in the lower animals and of prolonging life and of preventing diseases by methods derived from discoveries which had brought such unspeakable relief to the human race. He described how rabies had been stamped out while he was at the head of the Local Government Board and declared that that Board would never have embarked on that enterprise had it not been for the knowledge of the experts employed in experimental investigation on whose advice it was able to rely.

Dr. C. J. MARTIN, Director of the Lister Institute, in seconding the motion, which was unanimously agreed to, stated that the progress in the study of cancer was not realised by the public, and he observed that it was not generally known that one out of every eight women or 11 men who reached the age of 35 years was, according to the Registrar-General's Return for 1905 and 1906, fated to die from cancer.

Mr. H. T. BUTLIN moved a cordial vote of thanks to the chairman and in the course of his remarks refuted the allegation that those who were engaged in experimental research became callous in consequence of the experiments which they had performed.

The Hon. SYDNEY HOLLAND, who seconded the vote of thanks, declared that though they were not all researchers, nevertheless they were all searchers after truth.

Lord CROMER, in acknowledging the vote of thanks, referred to the energetic manner in which the society had been organised under the able direction of Mr. Stephen Paget.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary Comitia was held on June 18th, Sir R. DOUGLAS POWELL, Bart., K.C.V.O., the President, being in the chair.

The following announcements were made in reference to the lectures to be delivered before the College:—

The Gulstonian lectures for 1909 would be delivered by Dr. A. E. Russell; the Lumleian lectures by Dr. Norman Moore; the FitzPatrick lectures by Sir T. Clifford Allbutt; the Oliver-Sharpey lectures by Professor C. Scott Sherrington (Liverpool); and the Croonian lectures for 1910 by Dr. Arthur Gamgee.

A discussion then ensued on a matter which was declared to be *secreta collegii*.

The PRESIDENT dissolved the Comitia.

make it a common practice to apply as out-patients of St. Thomas's Hospital, and procure, by false representations, pills containing the sulphate of quinine, which, on their return, they retail with considerable profit, as the '*Thomas's Hospital Pills*,' to their aguish neighbours, amongst whom they are in great request. This extensive and disgraceful fraud (he adds), I conceive, deserves some inquiry on the part of the medical officers of the hospital, who have been most shamefully imposed upon, to the injury of the institution, and many medical practitioners."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9402 births and 3622 deaths were registered during the week ending June 20th. The annual rate of mortality in these towns, which had declined in the seven preceding weeks from 15·7 to 11·8 per 1000, further fell to 11·6 in the week under notice. During the first 12 weeks of the current quarter the annual death-rate in these towns averaged 14·0 per 1000, and in London during the same period it did not exceed 13·5. The lowest annual death-rates in the 76 towns during the week under notice were 5·0 in Barrow-in-Furness, 5·1 in Devonport, 5·6 in Hornsey, and 6·6 in Stockport; the rates in the other towns ranged upwards to 16·3 in Salford, 18·2 in Wolverhampton, 18·6 in Wigan, and 20·5 in Oldham. The death-rate in London during the week did not exceed 10·8. The 3622 deaths in the 76 towns during the week showed a further decline of 56 from the numbers returned in recent weeks, and included 299 which were referred to the principal epidemic diseases, against 355 and 324 in the two previous weeks; of these 299 deaths, 86 resulted from measles, 68 from whooping-cough, 64 from diarrhœa, 35 from diphtheria, 31 from scarlet fever, and 15 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases last week were equal to a mean annual rate of 1·0 per 1000 in the 76 towns, against 1·1 and 1·0 in the two preceding weeks; the rate from these diseases in London did not exceed 0·8 per 1000. No death from any of these epidemic diseases was registered last week in Halifax, St. Helens, York, Willesden, Leyton, or in nine other smaller towns; the annual death-rates from these diseases ranged upwards, however, to 2·5 in Wolverhampton and in Norwich, 2·8 in Salford, and 3·1 in Aston Manor. The fatal cases of measles in the 76 towns, which had been 84 and 89 in the two previous weeks, declined again to 86 in the week under notice, but caused death-rates of 1·1 per 1000 in Swansea and 1·5 in West Ham. The deaths from whooping-cough also declined last week to 68 from 103 and 100 in the two preceding weeks; the death-rate from this disease did not reach 1·0 per 1000 in any of the 76 towns. The fatal cases of diarrhœa, which had been 68 and 63 in the two previous weeks, were 64 last week; they included 20 in London, seven in Manchester and Salford, and four in Liverpool. The 35 deaths from diphtheria exceeded the number in the previous week by three, and included five in Bristol, three in Manchester and Salford, and two in Wolverhampton. The 31 fatal cases of scarlet fever also showed an increase and caused death-rates equal to 1·1 in Swansea and 1·2 in Aston Manor. Three of the 15 deaths from "fever" occurred in Norwich and were equal to a rate of 1·3 per 1000. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had declined in the seven preceding weeks from 2938 to 2600, had further fallen to 2565 on June 20th; 310 new cases were admitted to these hospitals during the week under notice, against 291 and 289 in the two preceding weeks. The deaths in London referred to pneumonia and to other diseases of the respiratory organs, which had steadily declined in the eight preceding weeks from 201 to 128, further fell to 115 in the week under notice, and were 34 below the corrected number in the corresponding week of the five years 1903-07. Eight deaths were directly referred to influenza during the week in London, against but two in the previous week. The causes of 35, or 1·0 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were again duly certified in London, Leeds, West Ham, Bradford, Newcastle-upon-Tyne, Hull, and in 51 smaller towns; ten uncertified causes of death were, however, registered last week in Liverpool, four in Birmingham, and three in Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 15·5, 14·3, and 13·2 per 1000 in the three preceding weeks, rose again to 14·7 in the week ending June 20th. During the first 12 weeks of the current quarter the annual death-rate in these eight towns averaged 16·6 per 1000, and exceeded by no less than 2·6 the mean rate during the same period in the 76 large English towns. Among the eight Scotch towns the death-rate during the week under notice ranged from 10·0 and 11·0 in Aberdeen and Paisley, to 16·0 in Glasgow and 16·7 in Greenock. The 517 deaths in the eight towns showed an increase of 53 upon the number in the previous week, and included 51 which were referred to the principal epidemic diseases, against 30 and 42 in the two preceding weeks; of these 51 deaths, 20 resulted from whooping-cough, 13 from measles, ten from diarrhœa, five from "fever," two from scarlet fever, and one from diphtheria, but not one from small-pox. These 51 deaths were equal to an annual rate of 1·4 per 1000, the mean rate from the same diseases in the 76 English towns during the same week being 1·0. The 20 fatal cases of whooping-cough showed an increase of nine upon the number in the previous week, and included 11 in Glasgow, four in Edinburgh, three in Dundee, and two in Paisley. The deaths from measles, which had been five and ten in the two preceding weeks, further rose to 1·3 in the week under notice, of which nine occurred in Glasgow and two in Leith. The ten deaths attributed to diarrhœa were fewer by two than the number in the previous week; eight were returned in Glasgow. The deaths referred to "fever" in the eight towns, which had been but three and two in the two preceding weeks, rose to five last week, all of which occurred in Glasgow; four were certified as cerebro-spinal meningitis and one as enteric fever. The fatal cases of scarlet fever and of diphtheria were fewer than in any recent week. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 85, 75, and 51 in the three preceding weeks, rose again to 73 in the week under notice, but were 13 below the number returned in these towns in the corresponding week of last year. The causes of 25, or 4·8 per cent., of the deaths registered in the eight towns during the week were not stated or not certified; in the 76 English towns during the same week the proportion of uncertified causes of death did not exceed 1·0 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 15·9, 16·5, and 19·2 per 1000 in the three preceding weeks, declined again to 16·5 in the week ending June 20th. During the first 12 weeks of the current quarter the death-rate in Dublin averaged 20·7 per 1000; the mean rate during the same period did not exceed 13·5 in London and 15·5 in Edinburgh. The 125 deaths of Dublin residents registered during the week under notice showed a decline of 20 from the number returned in the previous week, and included 14 which were referred to the principal epidemic diseases, against but nine and six in the two preceding weeks. These 14 deaths were equal to an annual rate of 1·9 per 1000, the rate during the week from the same causes being only 0·8 in London and 0·9 in Edinburgh. Of the 14 deaths from these epidemic diseases in Dublin, five resulted from measles, four from diarrhœa, three from whooping-cough, and two from diphtheria, but not one from scarlet fever, "fever," or small-pox. The fatal cases of measles, diarrhœa, and whooping-cough all showed an increase upon the low numbers returned in recent weeks. The 125 deaths from all causes in the city during the week included 21 of infants under one year of age and 28 of persons aged upwards of 60 years; both these numbers showed a decline from the numbers in the previous week. One inquest case and two deaths from violence were registered, and 49, or 39·2 per cent., of the deaths occurred in public institutions. The causes of five, or 4·0 per cent., of the deaths registered during the week were not certified. The causes of all the 990 deaths registered in diplomas of Fellowship to the remaining 19 successful candidates.

In accordance with a report from the Court of Examiners it was resolved to recognise the *Dreadnought* Hospital, Greenwich, for the additional year of surgical hospital practice required in the case of candidates for the Fellowship who are not Members of the College, and it was also resolved to place Laval University, Quebec, McGill University, Montreal, and the Italian Royal Universities on the list of Universities the degrees of which are accepted as qualifying for admission to the Final Examination for the diploma of Fellow.

It was resolved to issue diplomas of the Licence in Dental Surgery to four successful candidates.

In response to an invitation from the Pharmacopœia Committee of the General Medical Council it was resolved to send certain suggestions for the new pharmacopœia recommended by the special committee.

The following examiners were appointed:—Elementary Biology: James P. Hill and Thomas W. Shore. For the Conjoint Examining Board: Anatomy, W. H. Clayton-Greene, Arthur Robinson, and William Wright; and Physiology, Bertram L. Abrahams and J. Beresford Leathes. For the First Fellowship Examination: Anatomy, W. McAdam Eccles, Frederick G. Parsons, Arthur Thomson, and A. H. Young; and Physiology, T. G. Brodie, G. A. Buckmaster, C. F. Myers-Ward, and W. H. Thompson. For the Conjoint Examining Board: Midwifery, H. J. M. Playfair, W. R. Pollock, J. H. Targett, and W. W. H. Tate. For the Diploma in Public Health: Part I., H. R. D. Spitta; and Part II., H. T. Bulstrode. Mr. W. F. Haslam was re-elected a member of the Court of Examiners.

A letter was read from the President reporting the proceedings of the General Medical Council at its recent session. The best thanks of the Council were given to the President.

A letter addressed to the President was read from the Director-General of the Survey Department of the Egyptian Government asking that facilities might be given to Dr. G. Elliot Smith and Dr. Wood Jones of the Cairo Medical School to carry out in the Museum of the College an examination of a collection of material found in the course of excavations made in the Nile Valley and representing the varied races of people who inhabited Nubia in ancient times, together with their pathology and the results of their surgery, and stating that the Egyptian Government would offer to the Museum of the College the collection of material sent over for the purpose of this comparative study.

The PRESIDENT stated that he had informed the Director-General of the Egyptian Survey Department that facilities would be given to Dr. Elliot Smith and Dr. Wood Jones to carry out their investigations and that he felt sure the Council would gladly accept the handsome offer of the Egyptian Government.

It was resolved to inform the Egyptian Goverment that the Council would regard the collection of specimens as a most valuable addition to the Museum and would accept it with grateful thanks.

The PRESIDENT reported that he had undertaken to place a room at the College at the disposal of the authorities of the Imperial Cancer Research Fund for their annual meeting on July 14th, when the Duke of Bedford will be in the chair.

A committee was appointed to report on the answers received from the Fellows and Members regarding the admission of women to examination for the diplomas of the College.

A letter was read from Mr. Reginald J. E. Hanson, honorary secretary of "Lord Roberts's Boys" (City of London Schoolboys' Shooting Club), inclosing an account of two years' experimental work in physical training and stating that an expression from the College of an opinion on the great national value of a uniform and universal system of cadet training throughout the Empire would at this critical juncture be of great value to the national defence scheme. The President and Vice-Presidents were requested to draw up a reply.

A letter was read from Mr. J. W. Batterham, F.R.C.S., reporting that Mr. Thomas Lambert Hinton, who became a Member of the College in the year 1833, died at St. Leonards-on-Sea on June 14th at the advanced age of 100 years and 45 days.

The PRESIDENT reported that a meeting of Fellows would be held at the College on July 2nd for the election of four Fellows into the Council.

A committee was appointed to combine with any committee which might be appointed by the Royal College of Physicians of London for the same purpose to consider and draft a scheme which, if approved by the Colleges, should be submitted to the Senate of the University of London with the object of establishing a system of conjoint examination for the degrees of M.B. and B.S., and the diplomas of L.R.C.P. Lond. and M.R.C.S. Eng.

A suggestion was considered regarding the possibility of giving a reception at the College to the French medical practitioners who propose to visit this country from June 30th to July 2nd after the congress at Lille. Owing to the proposed arrangements of the visit and official engagements at the College it was found impossible to arrange a formal reception but facilities are to be given to the delegates for viewing the Museum and other parts of the College buildings.

LYNN THOMAS AND SKYRME FUND.

THE following subscriptions have been received between June 13th and 19th by Mr. William Sheen, M.S. Lond., F.R.C.S. Eng. (2, St. Andrew's-crescent, Cardiff), honorary secretary to the fund.

Subscriber of Two Guineas.

Sir Stephen Mackenzie, Dorking.

Subscribers of Two Pounds.

Burnley Division of British Medical Association, per James Gardner

Subscribers of One Guinea.

D. Arthur Davies, Swansea.
J. J. Macan, Cheam, Surrey.
John Myles, Dolgelly.
J. Herbert Simpson, Rugby.

Subscribers of Half-a-Guinea.

James Allan, Leeds.
G. MacLellan Blair, London.
Frank Savery, Ealing.

Subscriber of Ten Shillings.

Alfred Bethell, Lambourn, Berks.

Subscribers of Five Shillings.

H. A. Browning, Surgeon, R.N.
W. Joberns, Wolverhampton.

Subscriber of Half-a-Crown.

C. Smith, Leeds.

Looking Back.

FROM

THE LANCET, *SATURDAY*, June 26th, 1830.

BEDFORD AND NORTHAMPTON INFIRMARIES.—*A Bedfordshire Surgeon* complains, that to add to the many other disadvantages under which the members of the profession in his neighbourhood labour, "the house-surgeons of the Northampton and Bedford Infirmaries have of late taken to vaccinate gratuitously all persons who have thought proper to apply to them. The example was first set at the former hospital, and is now followed by the latter. It is no unusual circumstance (he adds) to see wagon-loads of children sent from the different parishes to be vaccinated at the infirmary, the whole parish not subscribing perhaps more than 2*l.* per annum to the institution. To such an extent is this practice adopted, that Mr. Marsh, house-surgeon to the Northampton Infirmary, in the course of a few months, vaccinated no less than 10,000 individuals, for which the liberal directors of the institution, with the Marquis of Northampton at their head, voted *him* the handsome present of 5*l.* from the funds of the hospital! These glaring injuries to the profession ought to be stopped; while young men are compelled to submit to all the drudgery of the dispensary, it is really hard that the more advanced practitioners, viz. the physicians and surgeons of these institutions, should do everything to prevent their obtaining honourable modes of living." If an excuse can be found for indiscriminate gratuitous practice in any branch of the medical profession, it certainly is offered in disseminating the protecting principle of the vaccine virus against the horrid ravages of the small-pox.

FRAUDS ON ST. THOMAS'S HOSPITAL.—*Mr. Dewhurst* informs us, that there are many persons residing in the neighbourhood of *Plumstead, in Kent,* "who

London during the week were duly certified, while in Edinburgh the proportion of uncertified causes of death was 7·0 per cent.

VITAL STATISTICS OF LONDON DURING MAY, 1908.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·2 per 1000 of the population, estimated at 4,795,757 persons in the middle of the year; in the three preceding months the rates were 7·8, 6·8, and 6·1 per 1000 respectively. The lowest rates last month were recorded in Kensington, Hammersmith, Chelsea, Stoke Newington, and Finsbury; and the highest rates in Hackney, Bethnal Green, Stepney, Poplar, and Deptford. A slight increase in the prevalence of scarlet fever was recorded last month; among the various metropolitan boroughs this disease was proportionally most prevalent in Hackney, Bethnal Green, Stepney, Poplar, and Deptford. The Metropolitan Asylums hospitals contained 2707 scarlet fever patients at the end of last month, against 3591, 3150, and 2868 at the end of the three preceding months; the weekly admissions averaged 342, against 410, 336, and 319 in the three preceding months. Diphtheria was less prevalent in May than in any previous month of this year; the greatest proportional prevalence of this disease was recorded last month in the City of London, Bethnal Green, Wandsworth, Lewisham, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums hospitals, which had been 1184, 1081, and 872 at the end of the three preceding months, had further declined to 804 at the end of last month; the weekly admissions averaged 105, against 149, 131, and 107 in the three preceding months. The prevalence of enteric fever also was less than that recorded in any other recent month; among the several boroughs the greatest proportional prevalence of this disease last month was recorded in Westminster, Finsbury, Shoreditch, Stepney, Bermondsey, and Wandsworth. There were 45 enteric fever patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 79, 73, and 45 at the end of the three preceding months; the weekly admissions averaged seven, against ten, ten, and seven in the three preceding months. Erysipelas was proportionally most prevalent in Shoreditch, Bethnal Green, Stepney, Bermondsey, Battersea, and Deptford. The 14 cases of puerperal fever notified during the month included three in St. Marylebone, two in Hampstead, and two in Poplar. Of the ten cases notified as cerebro-spinal meningitis two belonged to Bethnal Green, two to Lambeth, and one to each of six other boroughs.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending May 30th the deaths of 4486 persons belonging to London were registered, equal to an annual rate of 12·2 per 1000; in the three preceding months the rates were 17·4, 16·1, and 14·9 per 1000. The death-rates last month in the several boroughs ranged from 8·4 in Stoke Newington, 9·1 in Hampstead, 9·2 in Lewisham, 9·3 in Wandsworth, and 10·3 in Camberwell, to 14·1 in Shoreditch and in Stepney, 14·7 in Finsbury, 14·9 in Bermondsey, 15·4 in Southwark, and 15·6 in Poplar. The 4486 deaths from all causes included 332 which were referred to the principal infectious diseases; of these, 132 resulted from measles, 35 from scarlet fever, 31 from diphtheria, 85 from whooping-cough, six from enteric fever, and 43 from diarrhœa, but not any from small-pox, from typhus fever, or from ill-defined pyrexia. No death from any of these diseases was registered last month in the City of London; among the metropolitan boroughs they caused the lowest death-rates in Paddington, Chelsea, St. Marylebone, Hampstead, and Islington; and the highest rates in Hackney, Finsbury, Stepney, Poplar, Southwark, Lambeth, and Battersea. The 132 deaths from measles were 103 fewer than the corrected average number in the corresponding periods of the five preceding years; the greatest proportional mortality from this disease last month was recorded in Hackney, Finsbury, Shoreditch, Stepney, Poplar, and Battersea. The 35 fatal cases of scarlet fever showed no appreciable variation from the average number; this disease was proportionally most fatal in Fulham, Poplar, Bermondsey, Lambeth, and Camberwell. The 31 deaths from diphtheria were 14 below the corrected average; among the metropolitan boroughs the highest death-rates from this disease were recorded in Paddington, Hackney, Stepney, Poplar, Southwark, Bermondsey, and Lewisham. The 85 fatal cases of whooping-cough showed a decline of 70 from the average number in the corresponding periods of the five preceding years; whooping-cough was proportionally most fatal last month in Hackney, Stepney, Poplar, Southwark, Lambeth, and Battersea. The six deaths from enteric fever were equal to only half the average number; of these six deaths, two belonged to St. Pancras and one each to Hackney, Poplar, Southwark, and Deptford. The 43 fatal cases of diarrhœa were 26 below the corrected average number; this disease showed the greatest proportional fatality in Hammersmith, Hackney, Stepney, Poplar, Battersea, and Lewisham. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was 39·6 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 86 per 1000. No death at this age was registered in the City of London; among the metropolitan boroughs the lowest rates of infant mortality were recorded in Chelsea, St. Marylebone, Stoke Newington, Holborn, Finsbury, and Lewisham; and the highest rates in Kensington, Fulham, Stepney, Poplar, Bermondsey, Battersea, and Deptford.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

Captain William K. Steele to be Major (dated April 6th, 1908).

Colonel M. W. Kerin has been appointed Administrative Medical Officer at Tidworth, vice Colonel W. J. R. Rainsford, C.I.E., appointed to Plymouth.

THE TERRITORIAL FORCE.

Nursing Service.

The Army Council has decided to establish an Advisory Council which will frame rules for the admission of nurses into a nursing service for the general hospitals of the Territorial Force and make recommendations for the administration of the service and for the appointments of matrons and sisters. Her Majesty has become President of the Nursing Service and has approved of the appointment of the Duchess of Montrose as Vice-President. The council will consist of Surgeon-General Sir Alfred Keogh, K.C.B., K.H.P., Director-General, Army Medical Service (chairman), and the following members: The Duchess of Montrose (Vice-President), the Countess of Derby, the Countess of Jersey, the Lady Grenfell, the Lady Helen Munro Ferguson, Miss Haldane, Miss Cox-Davies, matron, Royal Free Hospital; Miss Hamilton, matron, St. Thomas's Hospital; Miss Hughes, Queen's Jubilee Institute; Miss McCall Anderson, matron, St. George's Hospital; Miss Ray, matron, King's College Hospital; Miss Vernet, Middlesex Hospital; Miss Sidney Browne, R.R.C., late matron-in-chief, Q.A.I.M.N.S. (secretary).

Sanitary Company for R.A.M.C. (2nd London Division).

At a meeting held on Thursday, June 18th, at the offices of the Metropolitan Asylums Board of the medical officers of the hospitals of the Board it was resolved, if possible, to raise a sanitary company of the Royal Army Medical Corps for the 2nd London Division.

The 4th County of London General Hospital.

Colonel Atwood Thorne, V.D., is organising the 4th County of London General Hospital with temporary headquarters at 148, Harley-street. There are vacancies for non-commissioned officers and men. Applications should be made to Colonel Thorne at 148, Harley-street, London, W.

DEATHS IN THE SERVICES.

Deputy Inspector General Henry Ashlin Close, R.N. (retired), on June 13th at Bedford. He entered the Navy in

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING MAY, 1908.

(Specially compiled for THE LANCET.)

CITIES AND BOROUGHS.	Estimated population in the middle of 1908.	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.											Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cerebro-spinal meningitis.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.*	Whooping-cough.	Typhus fever.	Enteric fever.	Other continued fevers.	Diarrhœa.	Total.	Annual rate per 1000 persons living.

* Including membranous croup.

phthisis is used apart from pulmonary tuberculosis should be in connexion with a disease of the eye. The next generation of ophthalmic surgeons might usefully turn their attention to the reorganisation and revision of the terminology of their specialty, a revision, nevertheless, which is bound sooner or later to take place, in view of the fact that science is always destructive to sentiment.

Yours truly,
Wimpole-street, W., June 12th, 1908. PERCY DUNN.

THE SPIROGRAPH.

To the Editor of THE LANCET.

SIR,—Your reviewer has not yet escaped from the toils of his own weaving. Sandmann, in the article to which I have been referred, says: "I make my patients breathe against a plate of *glass*" (italics mine), in order to obtain a temporary glass picture. Glass being transparent, the breath-picture does not show up clearly on its surface. For a permanent record Sandmann used "pasteboard covered over with *slate-paper*" (italics mine). On this plate, an example of which I send herewith, the moisture in the breath does not readily condense, obviously because pasteboard is a non-conductor of heat. Consequently the powder used to fix the image *does not* adhere.

I quote now from Wingrave's letter to THE LANCET of Jan. 26th, 1907, p. 253: "Slate, glass, and polished metals all have their shortcomings, but I have found that *vulcanite* gives a faithful image" (italics mine). Wingrave's spirograph, an example of which I also inclose, shows up the breath-picture and takes the fine powder, used to make a permanent record, in a most satisfactory manner. Sandmann's methods with glass and slate were failures. Wingrave's methods with vulcanite are successful. Yet my critic would have us believe they were "precisely" the same!

It may be, Sir, that I have not spent so many years in the service of Rhinology as my critic has done, but I hope when I have reached his position that I shall be able to criticise the work of other men with sound knowledge and fair judgment.

I am, Sir, yours faithfully,
Stratford-place, W., June 11th, 1908. DAN MCKENZIE.

To the Editor of THE LANCET.

SIR,—Those interested in Dr. McKenzie's defence of Dr. Wingrave's claims should read Sandmann's paper, which will prove that I was entirely correct in my remarks.

I am, Sir, yours faithfully,
THE REVIEWER.

TANSINI METHOD FOR THE CURE OF CANCER OF THE BREAST.

To the Editor of THE LANCET.

SIR,—If Professor Purpura's pathological views are admitted, the Tansini method may possess claims to consideration as a means of filling up the gap produced by the removal of a large area of skin from the front of the chest. Even for this purpose, however, Thiersch grafting is, in my opinion, much to be preferred, for the Tansini flap is an ill-nourished one and is obtained by what is practically a severe additional operation. These, however, are minor details. My main objection to the method is that it is based upon an erroneous pathology, that it ignores the laws which govern the spread of a carcinoma by permeation, and that it unites extravagance with false economy. As Professor Purpura's letter shows, the belief that breast cancer spreads mainly in the plane of the skin, with the corollary that "it is necessary to remove as much skin as possible," can only be supported by reference to opinion and authority, and is a product, not of the laboratory, but of the library.

I have shown elsewhere that recurrence *in the skin after* the operation for breast cancer is nearly always due to inadequate removal of the underlying deep fascia—the layer in which the microscopic growing edge of the cancer is found. Both in the Halstead method and in the Tansini method, which is a plastic modification of Professor Halstead's, removal of the deep fascia over the required circular area of ten inches or more in diameter is impossible without undermining the skin flaps—a step which forms no part of either operation. Although in my method removal of skin is limited to a circle four or five inches in diameter, I have only once seen recurrence in the skin. I would therefore reiterate a strong protest against the unnecessary sacrifice of healthy skin and the inadequate removal of the *deep fascia*, which have characterised operations for breast cancer. The Tansini method is an ingenious way of filling up a gap which need never have been created.

I am, Sir, yours faithfully,
Wimpole-street, W., June 20th, 1908. W. SAMPSON HANDLEY.

THE DANGERS AND TREATMENT OF MYOMA OF THE UTERUS.

To the Editor of THE LANCET.

SIR,—In his interesting Ingleby lectures Mr. Christopher Martin makes some remarks about the treatment of fibroid tumours of the uterus by electrolysis which I should like to refer to. To call Apostoli's treatment electrolysis is, of course, wrong. That is not of much importance, but it does seem to me right that credit should be given to Apostoli for his work. Mr. Martin writes as if he had never tried the treatment, but I have, and I know that Apostoli never recommended thrusting the electrode deeply into the growth, but insisted always on nothing more than a shallow puncture. This I have done hundreds of times without any ill result.

Mr. Martin also forgets that when Apostoli was treating patients with electricity the mortality was, to use his own word, "frightful," and that in 1891 the staff of the Birmingham Hospital for Women announced that they had practically abandoned the operation on account of the terrible death-rate. The change from the extra- to the *intra*-peritoneal method came so quickly and with such wonderful improvement in the results that three years after this announcement I wrote in my book on abdominal surgery: "Operations, when no special difficulties are expected, are now so safe that the question of safety alone would not be sufficient to make one advise electricity rather than an easy operation." I comparatively seldom advise Apostoli's treatment now, though in my experience the results after electricity have been permanent, simply because the mortality after hysterectomy is under 5 instead of being over 30 per cent. as it was 20 years ago. The analysis of Keith's and Englemann's statistics referred to showed such an amount of ignorance of what Apostoli's treatment aimed at that it has never seemed to be worth anything.

I am, Sir, yours faithfully,
June 20th, 1908. SKENE KEITH.

BLOWN MEAT.

To the Editor of THE LANCET.

SIR,—For your benefit I write to inform you in reference to your note on "Blown Meat" and Benjamin Firth Kettle, cattle-dealer, of Hassocks, that this man Kettle was summoned about eight weeks ago at the Haywards Heath petty sessions by the Cuckfield rural district council (which council forms one of the sanitary authorities of the East Sussex Combined Sanitary Authority, of which I am medical officer of health) for slaughtering an animal on unlicensed premises. On that occasion Kettle was defended by a solicitor who pleaded a technical objection because proof of the publication of the order of the Local Government Board made 26 years previously, conferring urban powers on the rural district council of Cuckfield to make by-laws in respect to slaughter-houses, was not produced. The Bench, in spite of the protest made by the clerk to the council, Mr. C. H. Waugh, dismissed the case. Mr. Waugh, clerk and solicitor to the rural district council of Cuckfield, advised the council to appeal. Such appeal was heard before the Lord Chief Justice and others a fortnight ago; it was held that it was not necessary to prove publication of the order made 26 years ago, and that if it was necessary then it was for the defendant to prove that the order had not been published. The case was remitted to the Haywards Heath Bench for a further hearing and on June 15th, 1908, the Bench convicted Kettle, fined him £1 and £5 10*s*. 2*d*. costs, or in default one month.

The difficulties as pointed out in your paper of obtaining suitable punishment for dealers in diseased animals and bad meat are considerable. However, the inclosed cutting from the Haywards Heath local paper shows that at times magistrates will impose suitable penalties. I think you will agree

July, 1859, was promoted staff-surgeon in 1872, and fleet-surgeon in 1881, retiring with the rank of deputy inspector-general of hospitals and fleets ten years later. He was in medical charge of the seamen and Royal Marines of the *Clio* landed at Panama during a revolutionary attack on the city in September, 1860.

THE KING'S BODYGUARD FOR SCOTLAND.

The King has been graciously pleased to signify His Majesty's approval of the following appointment on the staff of officers of the Royal Company of Archers (King's Body Guard for Scotland) made at the annual general meeting of the Royal Company on May 21st last:—To be Surgeon: Dr. William Allan Jamieson, vice Mr. Thomas Annandale, deceased.

Dr. William Robert Smith, V.D., Brigade-Surgeon-Lieutenant-Colonel (Honorary Surgeon-Colonel) 3rd London Volunteer Infantry Brigade, has been appointed Deputy-Lieutenant of the County of London (dated June 18th, 1908).

Correspondence.

"Audi alteram partem."

THE STUDY OF TWINS AND DOUBLES.

To the Editor of THE LANCET.

SIR,—Will you kindly allow me once again to appeal to your readers for additional information on the above subject, which the consideration of my present evidence has rendered advisable. My object is to determine the greater or lesser importance of the constitutional factor in disease and while still relying mainly on data derived from information respecting twins and doubles I wish to draw upon all subsidiary sources so as to obtain as complete an outline of the subject as is possible.

I have now evidence, though I should be glad of more, on the following points:—(*a*) *Similar* particular diseases and definite constitutional conditions in true twins like and unlike in respect to melancholia, bronchopneumonia, chorea, splenic anæmia, diabetes, hernia, influenza, quinsy and tonsillitis, conjunctivitis, bronchitis, convulsions, thrush, typhoid fever, scarlet fever, measles, cyclical vomiting, pulmonary tuberculosis, peritonitis, and caries of similar teeth. From the literature of the subject instances of suicidal insanity, exalted delusions, melancholia, mania, idiocy, imbecility, congenital deformities, conjunctivitis, and most of the commoner specific fevers. (*b*) Cumulative evidence of several similar diseases contracted nearly or quite simultaneously, sometimes in twins not living together. Confirmatory evidence from literature of the subject. (*c*) Cumulative evidence in triplets. (*d*) Reference to insanity in triplets. (*e*) Other characteristics shared in common in twins and triplets. Confirmatory evidence from literature of the subject. (*f*) Twins not of the same sex. Much less similarity but not unlikeness of constitution. (*g*) "Doubles." Two cases of particular diseases. Diabetes; tetanus. (*h*) "Doubles." One case of cumulative evidence. (*i*) Dissimilar diseases in twins, one doubtful case.

For help in collecting these instances together I wish specially to thank Mr. D. Biddle, Mr. C. Campbell, Dr. H. Campbell, Dr. S. Davies, Dr. R. Glass, Dr. C. Goring, Dr. R. Hutchison, Mr. A. D. Lewis, Dr. H. Maudsley, Mr. George Murray, Dr. H. Rayner, Dr. W. J. Rutherfurd, Dr. W. C. Sullivan, Mr. F. W. Twort, Dr. A. R. Urquhart, and others of Great Britain, and Dr. B. M. J. Conlin, Dr. C. Hedger, Dr. H. Lyons Hunt, Dr. J. Ratcliffe, Dr. Milton Sturgis, Dr. J. M. Trigg, and Dr. H. Yoder of America, and Mr. H. Rugg of Australia for useful suggestions and valuable particulars kindly given and all others who replied to my inquiries. I am also much indebted to the various medical journals which kindly afforded me space for my inquiries.

Further data required. 1. SIMILAR DISEASES IN:—(*a*) *Twins and triplets of the same sex.*—Like twins and triplets. Instances of one disease or, if possible, of several diseases. Unlike twins and triplets. Instances of one disease or, if possible, of several diseases. (*b*) *Twins and triplets not of the same sex.*—Like twins and triplets. Instances of one disease or, if possible, of several diseases. Unlike twins and triplets. Instances of one disease or, if possible, of several diseases. (*c*) "*Doubles*" *same sex, preferably adults.*—Instances of one disease or, if possible, of several diseases. (*d*) *Husband and wife.*—*Like*, the likeness consisting in similar *eye colour*, *similar complexion*, *similar height* characteristics, allowance being made for the fact that women are about four to five inches shorter than men. Unlike in above particulars. (*e*) *Parents and children.*—Like. Unlike. (*f*) *Brothers and sisters.*—Like. Unlike. DISSIMILAR DISEASES IN:—(*a*), (*b*), (*c*), (*d*), (*e*), (*f*), as above.

I should be glad, as the evidence is often difficult to interpret rightly, to have as many particulars in each case as possible. I cannot find satisfactory evidence for the statement that true uniovular twins are always of the same sex. If any of your readers could supply me with references to *detailed series of observations* on this point I should be still further obliged.—I am, Sir, yours faithfully,

J. LIONEL TAYLER.

8, Adys Lawn, Willesden-green, London, N.W., June 8th, 1908.

THE SOLECISMS OF OPHTHALMIC TERMINOLOGY.

To the Editor of THE LANCET.

SIR,—I have elsewhere upon several occasions directed attention to the absurdity of the continued use of the antiquated expression "ophthalmia" as applied to the purulent conjunctivitis of infants. Such a Græco-Latin hybridity as "ophthalmia neonatorum" is unscientific, pathologically inaccurate, and a relic of the days of bacteriological ignorance. The defence in favour of its retention is that custom, as it has been said, has "sanctified" its use—an argument somewhat lacking in strenuousness in view of the continued progress of the science of our art. If ophthalmic surgeons neglect to teach their students that the term "ophthalmia" neonatorum is obsolete, the present-day students are likely to inform the ophthalmic surgeons that bacteriologically they had been taught that the disease in question was not "ophthalmia" but purulent conjunctivitis. But this is only one of the many *solecisms* still prevalent and conservatively adhered to in ophthalmic practice. Presumably they are all "sanctified by use." Perhaps the most glaring instance is that of the term "sympathetic ophthalmia." To describe an inflammation as due to sympathy might usefully have supplied a want in the unscientific days of old. But to speak of sympathetic inflammation in these days is equivalent to asking students to believe in a tradition which has ceased to have any foundation in fact. If ophthalmic surgeons still persist in teaching students that sympathetic ophthalmia correctly describes that disease which is really an infective cyclitis then the students should press for an answer to the question "What is the pathology of sympathy?" It is wonderful, too, how the word "lenticular" enjoys such a vogue in ophthalmic literature. Obviously when the ophthalmic surgeon refers to "lenticular" débris he means "lental" débris; it is difficult to understand how the remains of a lens can be described as part of a little lens. Again, the term "crystalline lens" is undeniably high-sounding, magnificent, impressive, but the adjective is nevertheless unnecessary and superfluous. The ancient anatomists spoke of the crystalline humour to distinguish it from the vitreous humour and the aqueous humour. In each of the latter instances the term "humour" has, for brevity, ceased to be used, and yet the adjective "crystalline" is still applied to the lens as if to show that it were peculiar to a lens, and especially to the ocular lens, to be "crystalline." This calls to mind the solecism so frequently observed in obituary notices, wherein, say, Mrs. Smith is described as the widow or relict of the *late* John Smith, thus suggesting the problem of how a woman can be the widow of a *living* husband.

Then there is that fearsome monstrosity, phthisis bulbi, employed to describe an atrophic condition of the globe. Pathologically, perhaps, the term may be correct. But that is not the point. I particularly draw attention to it for the purpose of showing the confusion to which terms "sanctified by use" can lead. Phthisis, which only means wasting, has by custom come especially and exclusively to mean tuberculosis of the lungs. On this showing, therefore, "phthisis bulbi" can only imply tuberculosis of the globe, whereas the atrophic condition of the globe in question has nothing whatever to do with the tubercle bacillus. It is somewhat remarkable that throughout the domain of the nomenclature of disease the only instance in which the term allowed full control one half of the officers could in peace time be away and arrangements for relieving and exchanging duties when officers were sick or needed leave would be done by the principal medical officer. I wish most strongly to point out that provided he can join within 24 or 48 hours one medical officer might be absent from his ship for months at a time; this in the Channel or Home Fleets. There are no duties that cannot be as easily managed by a surgeon as by a fleet surgeon, and, as you probably know, the surgeon is generally fresher at his work.

I quite agree with you that purely naval grievances come second to medical but there are many that are worthy of attention. The power given to a medical officer generally is very small and he usually only advises and cannot command, and has to mildly submit the diagnosis of all his cases to the captain of the ship and frequently answer questions on his methods of treatment. This causes much difficulty, especially in the case of venereal disease. As to cabin accommodation, though difficulty rarely arises, the regulations state that THE medical officer is to have a cabin; perhaps you do not realise the ignominious position the junior is placed in by the official status he occupies. Further, if a medical officer is appointed late he may have to put up with a cabin inferior to that held by many of his juniors, as if a cabin has once been allotted to any officer he cannot be turned out unless it is a marked cabin. Also, in ships on trooping service a medical officer on passage has to take a cabin after all the officers of the ship and may even have to go without. The question of boats is one of the reasons why medical officers cannot visit their own hospitals sufficiently, but from my experience the commanding officer has enough trouble to supply others besides the medical officers. The boat question affects all officers. Owing to messing arrangements, unless willing to be considerably out of pocket, medical officers cannot regularly visit their hospitals during working hours. There is room for improvement in the practice of putting an officer on half pay between his two appointments for no other obvious reason than to make him pay his own travelling expenses, which are thus doubled. Also the delay in promoting them to higher ranks when a vacancy occurs.

As regards being placed in the same position as army medical officers, naval officers certainly do not wish that. If the senior medical officer of a naval hospital had power to give small punishments for offences arising out of the improper performance of medical duties by the sick berth staff, or if he deemed a severer sentence necessary could, after first trying the case, recommend the sentence to the executive officer or have it confirmed by him, it would prevent occurrences such as the following. A second sick berth steward at a depôt was disrated for having passed a catheter on a patient at midnight. He took the responsibility of doing this as the catheter had only been passed a few hours previously, and he had been frequently encouraged to do minor details for the surgeons to avoid calling them. This sentence ruined his career and none of the medical officers were able to do anything for him, although he was considered one of the best and most promising men in the depôt.

What you say as to the course of instruction at Haslar and the want of pathologists and clinical teaching at any hospital is, I think, far too mild. We have no specialists of any sort, and medical officers who can examine a fundus or detect an error of refraction even amongst the highest ranks are rare. Honestly, the course of instruction at Haslar is regarded as a farce throughout the service except in the tropical diseases section. What you say as to an amalgamation with the Army Medical School is, I think, a proposal that all, except those enjoying the special billets at Haslar for our own course, would welcome, and the necessity for payment of officials to teach at our own hospitals would diminish if more opportunities for hospital study were given.

Lastly, I think it only fair that some attention should be paid to the sick berth staff. They have a very brief and indifferent instruction at a naval hospital—their pay bad and promotion very slow. The great concession of warrant rank to this branch has not done much good, as there are so few warrants and promotion is extremely slow and even to first-class steward is by rotation. Then the manner of their employment is bad; there is no distinction between nursing and non-nursing sections. A nurse in charge of a special case in a single bed cabin has to scrub the floor as well as do any surgical dressings. Some hospitals, especially the smaller ones, are so understaffed that when they have a special or infectious case nurses from the wards have to do the work, and there is then double work for the ward staff. It would be a good thing to copy the army by having a nursing and non-nursing section with an examination of higher quality than what we have at present. This examination, although unpopular, would of necessity give rise to better instruction. The sick berth staff are anxious to obtain the same rates of pay and promotion as naval writers.

I am, Sir, yours faithfully,

SURGEON, R.N.

June 22nd, 1908.

THE MANCHESTER PUBLIC ABATTOIR.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

IN the construction of a municipal abattoir Manchester has the honour of having been early in the field and suffers in consequence. The Manchester abattoirs were opened at Christmas of the year 1872. This was before the development of bacteriology, before any definite notion of asepsis existed, in fact, before any really scientific basis could be provided to guide the planning of a building where foodstuffs were to be preserved from the risk of contamination. In these circumstances it is not surprising to find that the abattoir is in no wise up to date. It is divided into small compartments which are let out to different butchers; therefore, it amounts to this, that the butcher has a small private slaughter-house at the public abattoir. But as these private places are only separated from each other by partition walls the inspectors have not far to go in visiting them. Then, on the butcher's side, there is this advantage, that overhead rails enable him to convey easily his meat to the cooling place or the meat market. Further, and in 1894, a cold storage was erected and it is a great advantage to have all this on the same premises. Then again, as it was constructed long ago, Manchester had not grown to its present dimensions and thus to-day the abattoir, the cold storage, and the wholesale meat market are in what has become a central position. This is a great convenience to the trade. On the other hand, the nearer to habitations the greater becomes the necessity of insuring the maintenance of sanitary conditions. Unfortunately, the Manchester slaughter-house is the reverse of a model establishment. There are low buildings and blood flows out from under the doors on large pavement stones which are not cemented together. The subsoil must be contaminated in the passages and courts between the buildings. Inside the slaughter pens there is insufficient light; they are paved with concrete which has worn well. A few have flag-stones with "plenty of grit"—that is, they are sufficiently rough not to be slippery. This is needed not only to prevent the men and beasts from slipping and falling but also so as to be able to work a lever under the carcass when it is necessary to move its position. These small slaughter pens or partitions are not over clean. They do not compare favourably even with the La Villette abattoir in Paris. There is a lack of smartness and brightness and there are many sombre places which help to produce a forbidding effect.

By a strange lack of appreciation of what constitutes the requirements of an abattoir the very department which needs the greatest amount of light and the most careful ventilation is the very worst part of the entire premises. The pigs are killed in a small dark structure where no special means of ventilation are provided. Overhead there is a low roof with many rafters that cannot possibly be cleaned. Here the accumulated dust and dirt are kept warm and damp by the constant supply of steam from the vats in which the carcasses are scalded so as to remove the bristles. It will be remembered that at Birmingham there is over these vats a different sort of roof so as to carry the steam away immediately and to prevent it from going towards the other parts of the slaughter hall where the carcasses are dressed. Nothing of the sort exists at Manchester. There is no such systematic division of labour with different sorts of ventilation and of light according to the nature of that labour. The whole compartment is bad and offers no advantage over a private slaughter-house, beyond the fact, of course, that it is easier to inspect. For this work there are three veterinary surgeons and one inspector of meat. Then there are also one inspector and two assistant inspectors for fish and fruit and they also visit the retail meat shops in different parts with me that this proves at any rate rural sanitary authorities are not so indolent as some good folk will have us believe.

I am, Sir, yours faithfully,
Hugh Stott,
Medical Officer of Health, Combined Sanitary
Authorities of East Sussex,
Lewes, Sussex, June 16th, 1908.

*** The newspaper cutting to which Mr. Stott refers gives a full account of the hearing before the Haywards Heath Bench on Feb. 24th of a charge against a butcher named Botting of Hurstmonceux. He was convicted in three cases for exposing meat in an advanced condition of tuberculosis for sale. The carcass of a pig in his possession was found to be tuberculous in nearly every part. The man had a good record, but the Bench rightly took a serious view of his offences and fined him £50, with 5 guineas costs.—Ed. L.

A QUESTION OF MEDICAL DEFENCE.

To the Editor of The Lancet.

Sir,—We note that in The Lancet of June 13th it is suggested by a correspondent "that an insurance company might be willing to issue a policy covering medical practitioners against the risk of damages being awarded against them for alleged negligence or malpractice." We desire to state that such a policy is now being issued to our clients by one of the leading non-tariff companies. The premium depends on the amount of indemnity required. The question of champerty and maintenance has been fully considered, and we are legally advised that there is no possibility of any action of this character.

It has been said that to give a medical practitioner complete indemnity against damages and legal expenses will tend to carelessness, but we fail to see how this can be true. There will still remain the moral stigma and the inevitable loss of practice which would follow an adverse verdict.

We are, Sir, yours faithfully,
43, Warwick-street, Regent-street, W. **Aked & Aked.**

THE ROYAL NAVY MEDICAL SERVICE.

To the Editor of The Lancet.

Sir,—I have read with great interest your leading article on the Royal Navy Medical Service in your number of May 30th last. As the subject is one which in order to attract that amount of attention that will lead to any hope of reform, needs further discussion it would be very kind of you to spare room in your valuable paper for further correspondence. Firstly, let me thank you on behalf of many with whom I have discussed it for that valuable article, which, although putting the case very mildly, is extremely fair and accurate. As regards the appointment of the new Director-General you are quite right. From what I have heard without exception his appointment has been spoken of as a great thing, and, moreover, was hopefully talked of for some considerable time before there was any chance of a vacancy. This fact shows one of the very great causes of complaint and reasons for thinking that there is need of serious attention to the present state of the service. There is a universal expression of opinion by senior (here let me state that I have always discussed these matters with seniors who usually all agree with me) as well as junior officers that the position of Director-General is no enviable one and the majority sympathise with him; this because definite statements made to medical officers when visiting the Admiralty show that he is merely a figure-head and, in fact, is treated in a very undignified manner as the senior of his department; that changes are made with which he does not agree and that it is not on his opinion or by his direction that the service is managed. Now the present Director-General has the reputation of being a man of firm character who will not be afraid to resist the authorities and who will do his best to carry out such plans as he may think necessary. It is commonly said that the Admiralty loathe to appoint the best man to this appointment as they do not want anyone whom they cannot easily manage. Hence probably the reason that men conspicuous for their professional abilities do not reach that post. Now in his present isolated position the Director-General is very helpless to carry out any radical changes, changes that most of us think ought to be made. We have, it is true, a "Medical Consultative Board" (please do not let those gentlemen think I have any animus against their personal abilities), but they do not form any part of the medical branch at the Admiralty; they examine candidates for entry and promotion, and even in those matters their advice is not taken. Would it not be a good thing if one or all of the members of that board would answer some of the following questions? I strongly appeal to them as representing the highest branch of the medical profession to do so and to interest themselves on behalf of their medical colleagues who in their present position are unable to agitate except anonymously.

1. Do they think that as constituted at present they have the power to assist the general working and efficiency of the service? or are they purely consultative and not allowed to advise? Do they fully realise that the medical officers of the service look to them for help?

2. Are they able in their present position to support the Director-General in his dealings with the Admiralty? and if not do they think that a board under altered conditions and with power to act as a body would do better?

3. Are they fully acquainted with the inner working of our naval hospitals and institutions, the manner of appointments, the lack of practice and unfair distribution of hospital courses and appointments in which medical officers can gain experience? Do they realise that many serve continuously at sea and never have any opportunity of showing their professional abilities, and that there is no method by which the Admiralty can ascertain them, and that social influence far outweighs professional ability?

4. Do they not think that charges such as the following would benefit the Royal Navy as a whole and that they would justify additional expenditure? (*a*) To increase the staff of all the naval hospitals and to make appointments to these institutions shorter so as to make way for more medical officers to pass through them annually. (I believe, Sir, that no one can deny that with the present small number of vacancies at hospitals there are not enough places at these institutions for every medical officer to hold one vacancy once in every eight years, nor are hospital courses awarded in sufficient numbers to do this by one quarter.) (*b*) That the three large naval hospitals should be used as teaching centres for all medical officers indiscriminately. (*c*) That medical officers might, if willing, be allowed to proceed on full-pay leave for 6–12 months to study at civil hospitals, or even hold house appointments at civil hospitals if able to obtain them. (This is at present allowed to be done by medical officers on joining, but without pay; but it is later during our career that we need it so badly.) It is a fact that an army medical officer has lately held for some months such an appointment at a large London hospital as there was not sufficient work for him in the district in which he was serving.

Now these medical officers would thus make themselves more efficient, to the benefit of the service as well as themselves, and it would prepare the way for suitable men to obtain experience so as to act as pathologists, anæsthetists, aurists, oculists, &c., and instructors to the surgeons on entry, and, most important of all, instructors to the sick berth staff. Certainly strict care should be taken that only hard-working officers obtained these privileges and furnished proof of their work and that the privilege was not given in the same way to people wanting a holiday or avoiding half pay, as has been done over the present hospital courses. Most certainly if the medical officers are to prevent themselves falling into that state of professional ignorance and uselessness, as is so marked in the case of many senior officers (the fault lies with the system, not the officers), some arrangement should be made that after two years at sea a medical officer should always have at least three months at a naval or civil hospital.

Now how are these medical officers to be spared? It is a fact that we are nearly 80 short of our numbers but for all that they are easily obtained. If more are recruited it will not increase the number of hospital appointments. You say in your article that the constant presence of medical officers in harbour ships, &c., is necessary. That is where you show your want of experience of the inner workings. You will find that the majority of men admit the fact that the constant presence of two men in any ship in the Navy is quite unnecessary. Much more so in ships with nucleus crews. If they are supposed to be able to be quickly mobilised why cannot the medical officers be borne on the ship's books and mobilise if wanted at 24 hours' notice. In the Channel Fleet there is not work for one medical officer on any ship. Provided that the principal medical officer of the fleet was allowed full control one half of the officers could in peace time be away and arrangements for relieving and exchanging duties when officers were sick or needed leave would be done by the principal medical officer. I wish most strongly to point out that provided he can join within 24 or 48 hours one medical officer might be absent from his ship for months at a time; this in the Channel or Home Fleets. There are no duties that cannot be as easily managed by a surgeon as by a fleet surgeon, and, as you probably know, the surgeon is generally fresher at his work.

I quite agree with you that purely naval grievances come second to medical but there are many that are worthy of attention. The power given to a medical officer generally is very small and he usually only advises and cannot command, and has to mildly submit the diagnosis of all his cases to the captain of the ship and frequently answer questions on his methods of treatment. This causes much difficulty, especially in the case of venereal disease. As to cabin accommodation, though difficulty rarely arises, the regulations state that THE medical officer is to have a cabin; perhaps you do not realise the ignominious position the junior is placed in by the official status he occupies. Further, if a medical officer is appointed late he may have to put up with a cabin inferior to that held by many of his juniors, as if a cabin has once been allotted to any officer he cannot be turned out unless it is a marked cabin. Also, in ships on trooping service a medical officer on passage has to take a cabin after all the officers of the ship and may even have to go without. The question of boats is one of the reasons why medical officers cannot visit their own hospitals sufficiently, but from my experience the commanding officer has enough trouble to supply others besides the medical officers. The boat question affects all officers. Owing to messing arrangements, unless willing to be considerably out of pocket, medical officers cannot regularly visit their hospitals during working hours. There is room for improvement in the practice of putting an officer on half pay between his two appointments for no other obvious reason than to make him pay his own travelling expenses, which are thus doubled. Also the delay in promoting them to higher ranks when a vacancy occurs.

As regards being placed in the same position as army medical officers, naval officers certainly do not wish that. If the senior medical officer of a naval hospital had power to give small punishments for offences arising out of the improper performance of medical duties by the sick berth staff, or if he deemed a severer sentence necessary could, after first trying the case, recommend the sentence to the executive officer or have it confirmed by him, it would prevent occurrences such as the following. A second sick berth steward at a depôt was disrated for having passed a catheter on a patient at midnight. He took the responsibility of doing this as the catheter had only been passed a few hours previously, and he had been frequently encouraged to do minor details for the surgeons to avoid calling them. This sentence ruined his career and none of the medical officers were able to do anything for him, although he was considered one of the best and most promising men in the depôt.

What you say as to the course of instruction at Haslar and the want of pathologists and clinical teaching at any hospital is, I think, far too mild. We have no specialists of any sort, and medical officers who can examine a fundus or detect an error of refraction even amongst the highest ranks are rare. Honestly, the course of instruction at Haslar is regarded as a farce throughout the service except in the tropical diseases section. What you say as to an amalgamation with the Army Medical School is, I think, a proposal that all, except those enjoying the special billets at Haslar for our own course, would welcome, and the necessity for payment of officials to teach at our own hospitals would diminish if more opportunities for hospital study were given.

Lastly, I think it only fair that some attention should be paid to the sick berth staff. They have a very brief and indifferent instruction at a naval hospital—their pay bad and promotion very slow. The great concession of warrant rank to this branch has not done much good, as there are so few warrants and promotion is extremely slow and even to first-class steward is by rotation. Then the manner of their employment is bad; there is no distinction between nursing and non-nursing sections. A nurse in charge of a special case in a single bed cabin has to scrub the floor as well as do any surgical dressings. Some hospitals, especially the smaller ones, are so understaffed that when they have a special or infectious case nurses from the wards have to do the work, and there is then double work for the ward staff. It would be a good thing to copy the army by having a nursing and non-nursing section with an examination of higher quality than what we have at present. This examination, although unpopular, would of necessity give rise to better instruction. The sick berth staff are anxious to obtain the same rates of pay and promotion as naval writers.

I am, Sir, yours faithfully,
SURGEON, R.N.
June 22nd, 1908.

THE MANCHESTER PUBLIC ABATTOIR.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

IN the construction of a municipal abattoir Manchester has the honour of having been early in the field and suffers in consequence. The Manchester abattoirs were opened at Christmas of the year 1872. This was before the development of bacteriology, before any definite notion of asepsis existed, in fact, before any really scientific basis could be provided to guide the planning of a building where foodstuffs were to be preserved from the risk of contamination. In these circumstances it is not surprising to find that the abattoir is in no wise up to date. It is divided into small compartments which are let out to different butchers; therefore, it amounts to this, that the butcher has a small private slaughter-house at the public abattoir. But as these private places are only separated from each other by partition walls the inspectors have not far to go in visiting them. Then, on the butcher's side, there is this advantage, that overhead rails enable him to convey easily his meat to the cooling place or the meat market. Further, and in 1894, a cold storage was erected and it is a great advantage to have all this on the same premises. Then again, as it was constructed long ago, Manchester had not grown to its present dimensions and thus to-day the abattoir, the cold storage, and the wholesale meat market are in what has become a central position. This is a great convenience to the trade. On the other hand, the nearer to habitations the greater becomes the necessity of insuring the maintenance of sanitary conditions. Unfortunately, the Manchester slaughter-house is the reverse of a model establishment. There are low buildings and blood flows out from under the doors on large pavement stones which are not cemented together. The subsoil must be contaminated in the passages and courts between the buildings. Inside the slaughter pens there is insufficient light; they are paved with concrete which has worn well. A few have flag-stones with "plenty of grit"—that is, they are sufficiently rough not to be slippery. This is needed not only to prevent the men and beasts from slipping and falling but also so as to be able to work a lever under the carcass when it is necessary to move its position. These small slaughter pens or partitions are not over clean. They do not compare favourably even with the La Villette abattoir in Paris. There is a lack of smartness and brightness and there are many sombre places which help to produce a forbidding effect.

By a strange lack of appreciation of what constitutes the requirements of an abattoir the very department which needs the greatest amount of light and the most careful ventilation is the very worst part of the entire premises. The pigs are killed in a small dark structure where no special means of ventilation are provided. Overhead there is a low roof with many rafters that cannot possibly be cleaned. Here the accumulated dust and dirt are kept warm and damp by the constant supply of steam from the vats in which the carcasses are scalded so as to remove the bristles. It will be remembered that at Birmingham there is over these vats a different sort of roof so as to carry the steam away immediately and to prevent it from going towards the other parts of the slaughter hall where the carcasses are dressed. Nothing of the sort exists at Manchester. There is no such systematic division of labour with different sorts of ventilation and of light according to the nature of that labour. The whole compartment is bad and offers no advantage over a private slaughter-house, beyond the fact, of course, that it is easier to inspect. For this work there are three veterinary surgeons and one inspector of meat. Then there are also one inspector and two assistant inspectors for fish and fruit and they also visit the retail meat shops in different parts of the city. Such a staff is absolutely insufficient for a large town like Manchester. Fortunately, their work is simplified by the fact that the private slaughter-houses are dying out. Nearly every year an old private slaughter-house disappears and no new ones are sanctioned. It was eight or nine years ago that the last permission to open a private slaughter-house was granted. This, however, was an exceptional case, as it was very far away from the centre of the city. Whenever a pretext arises to close a private slaughter-house the opportunity is not lost. What this means is illustrated by the fact that in 1906 the number of cattle slaughtered at the public abattoir was 35,304 and in the private slaughter-houses 9048. While Manchester has grown in size and population the private slaughter-houses have decreased. Moreover many butchers who have private slaughter-houses do not kill so frequently in them but are content to buy meat at the wholesale meat market. If they are a long way from the meat market then they kill more in their own places. Also during a quiet week, Easter week, for instance, many of these butchers do not kill at all but trust to finding at the meat market attached to the public abattoir all that they are likely to want. From the public health point of view this sort of gradual evolution is most welcome. It proves that the total abolition of private slaughter-houses would be no great hardship to the butcher, and the actual reduction in their number or the frequency with which they are used is so much gained in regard to the sanitation of the districts where they are, or were, situated. The charge made for slaughtering at the public abattoir is very low, namely, 1*s*. 6*d*. for cattle, 4*d*. for calves, 2*d*. for sheep and lambs, and 6*d*. for hogs. What really pays is the rent charged for stalls to expose and to sell in the wholesale meat market.

There is no doubt also that the importation of live cattle and of meat from abroad has largely contributed to make butchers resort to the market instead of themselves killing. If this meat consists of what is called "split meat," that is, of an entire half of a carcass, the inspectors maintain that it is easy to see if the meat is sound. There are notably some splendid quarters of American beef. These animals are carefully reared and scientifically fed. The veterinary surgeon, with whom I discussed the matter, said that if instead of killing these American cattle immediately on landing they could be sent out to graze for a little while they would soon utterly destroy the British cattle breeding trade. Yet in Lancashire there is a marked preference for Danish beef. It does not look so nice because it is chilled and loses colour. But it is not so fat and is said to taste better. It is a curious fact that in London and the south of England people will readily buy and eat fat beef. Not so in Lancashire where the ideal is a bullock two years old that has not been fattened. There is at least this to be said that with lean meat there is less waste, therefore it is cheaper. However this may be, the concentration of the trade in one large market is a great advantage to the public. It greatly simplifies the control. But what is known as "box" meat cannot be controlled at all and therefore should not be admitted. This consists of odd and small pieces of meat coming from a variety of carcasses, packed in wooden boxes and kept in cold storage till the moment of their sale. Where the whole side of an animal is hung up, even though the viscera have been removed, it is comparatively easy to recognise really wholesome meat, but the sodden, damp, and small lumps of meat that are taken out of the boxes are most unsatisfactory. Short of an elaborate analysis of each piece, which would cost more than the meat is worth, it is not possible to tell whether it is absolutely wholesome or not. There is a very strong feeling against this "box" meat as constituting a real danger.

In regard to English meat there are also serious difficulties. No man ought to be allowed to kill a beast on a farm unless he informs the authorities, so that they may send an inspector to examine the animal the moment that it is killed. But so far is this from being the case that there is a regular trade known as the "slink" trade, which consists of purchasing from farmers sick animals, killing them, and selling wherever the control is not very severe and there is a good chance that the unwholesome nature of the meat will not be discovered. This is the advantage of a public meat market such as that of Manchester. Recently one man had 16 sides of beef seized in the course of one week. The private slaughter-house in a rural district where the meat seized came from had not been inspected for three months. Many inspectors in rural districts are absolutely incapable of detecting dangerous meat even if they did inspect. A far larger staff of competent inspectors is needed all over the country. At the wholesale meat market it is comparatively easy to maintain a higher moral tone. There the "slink" butcher gets worried out of the place. Indeed, the inspectors assured me that there was not a "slink" butcher remaining in any part of the city. If a new butcher came he was most carefully watched and his meat inspected so often that he soon found it would not pay to deal in unwholesome meat. Such, in any case, is the opinion entertained by some of the inspecting staff with whom I conversed.

In conclusion, it seems to me that the time is approaching when Manchester must build a new abattoir. This should coincide with the abolition of the few remaining private slaughter-houses. Then the cattle market being at Salford the animals bought for slaughter have to be driven through crowded streets, and this is most inconvenient. The actual site is so near the centre that it might be sold for a very high price and the proceeds would help to build a new abattoir further from the city but near several rail- and water-ways and close to the, if necessary, new cattle market. Undoubtedly the cattle market and abattoir should be side by side and this is generally so contrived. It is time that this question should be taken in hand again and a complete and remunerative scheme devised. There can be no safer investment when private slaughter-houses are abolished. From the sanitary point of view it is essential that public abattoirs should comprise the utilisation of the by-products, as their treatment, if not properly managed, creates a greater nuisance than the mere slaughtering. On the other hand, it is just the by-products that insure the financial success of an abattoir. Therefore for this purpose also Manchester needs a new abattoir, a much more complete, modern, and better devised establishment than that which was built some 36 years ago.

LITERARY INTELLIGENCE.—A reprint has been called for of Dr. Hackworth Stuart's pamphlet on the medical inspector of public elementary school children under the Education (Administrative Provisions) Act, 1907. The pamphlet is based on Dr. Hackworth Stuart's four years' experience as medical officer to the Hanley Education Committee. It is published by Mr. H. K. Lewis under the title of "The Doctor in the Schools."

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on June 18th, when Dr. F. H. Champneys occupied the chair. A letter from the Privy Council was received approving the Board's suggested addition of the words "by examination" to Rule E 26 in the following terms:—

> Provided that a midwife whose name has been admitted to the Roll in virtue of having passed the examination of the Central Midwives Board, or in virtue of a qualification under Section 2 of the Midwives Act, 1902, acquired by passing an examination in midwifery may add the words "by examination" after the words "certified midwife."

A letter was read from the Master of the Coombe Hospital, Dublin, inquiring whether two probationers, working together and helping each other to conduct the delivery, can each obtain credit for a conduction. It was decided that the Master should be informed that the Board will not tolerate the slightest relaxation of its rules relating to attendance on cases. Letters were considered from the town clerk of Rotherham as to the conviction of a midwife under Section 1 (1) of the Notification of Births Act, 1907, and the Board decided that inquiries should be made (1) as to who were present at the birth in respect of which the midwife was convicted of failing to notify, and (2) as to whether the local supervising authority finds a *primâ-facie* case within the meaning of Section 8 (2) of the Midwives Act, 1902. A letter was read from the secretary of the Queen Victoria Jubilee Institute for Nurses as to providing facilities for the written examination in Ireland of candidates for the Central Midwives Board certificate. It was decided that the Queen Victoria Jubilee Institute for Nurses should be informed that the Board regretted that it could not accede to the request. The statement to be submitted to the Privy Council as to the payment of fees of medical practitioners summoned to assist midwives in emergencies was further considered and approved. The chairman reported that he had drawn up a leaflet on cancer of the womb for distribution to midwives and others. This leaflet, the essence of the message of which is that malignant disease of the uterus is fatal unless early diagnosis can be made and followed up by immediate operative treatment, will be supplied to anyone applying and paying the postage.

NOTES UPON HEALTH RESORTS.

SCANDINAVIAN WINTER HEALTH STATIONS.

(BY A SPECIAL COMMISSIONER.)

VI.[1]

SWEDISH HEALTH STATIONS.

SWEDEN to most Englishmen is probably one of the most unknown and least explored of European countries. Such ignorance and neglect are inexcusable and entail a sacrifice of opportunities and also of privileges which can ill be spared. This land offers almost ideal conditions for the health-seeker and holiday-maker. Nature has been bountiful in providing Sweden with a rich variety of inland and sea-coast districts, far-extending highlands and extensive lakelands, wide-stretching forests and numerous rivers, facilities and endowments dependent on natural resources equalled by few countries and surpassed by none. Added to these benefits are climatic conditions which, at least during a great part of the year, are peculiarly beneficial for bodily development and the maintenance of a high standard of health. Sweden is enabled to provide exceptional diversity in the characteristics of its health resorts. It can justly claim to possess the means for providing all the year round health and recreative centres of the first quality. And yet it must be admitted that up to recently the Swedes themselves have been slow to realise their blessings and hesitant to avail themselves of the natural benefits which, rightly understood and judiciously used, might well make their land one of the most popular and frequented of European countries. Now, however, mainly through the enterprise and energy of the Swedish Tourist Association, directed by its able secretary, Mr. Vilhelm Langlet, to whom I am indebted for much information and no little kindness, the various health stations are being organised, and by coördination and coöperation much is being accomplished in the developing of the best resorts. It is the case, however, that comparatively few prospectuses are printed in English. The slowness to advertise Swedish health resorts to the far wandering English health seeker and sportsman seems inexplicable. I have no doubt if Englishmen can but be afforded proper information in their own language there will be many desirous of availing themselves of the advantages of this east land of Scandinavia. The Swedish Tourist Association (Svenska Turestföreningen) has excellent central offices at 2, Norrlandsgatan, Stockholm, where particulars of practically all the Swedish health and sports centres may be obtained. Mr. Langlet and members of his staff speak English and all actual or intending visitors to Stockholm or any other part of Sweden would do well to communicate with this centre of thoroughly trustworthy and up-to-date information.[2]

Swedish winter sports.—Ski-jumping at Saltsjöbaden, near Stockholm.

ACCESS TO SWEDEN.

To many Sweden seems a land far off. As a matter of fact, it is very accessible and may be easily and comfortably reached. Good sailors may be advised to take the sea route, while sufferers from *mal de mer* and invalids will perhaps prefer one of the so-called overland routes. The vessels of the Wilson line starting from Hull and crossing to Christiania are very comfortable.[3] Thence a night's journey in a well-equipped "sleeper" will bring the traveller either to Stockholm or Gothenburg, the two centres which at the present form the best starting points for English visitors. If preferred, the direct service from Hull to Gothenburg by the Wilson line may be selected. The Thule line, a Swedish service, maintains a regular service between London and Gothenburg and Granton and Gothenburg.[4] Some advise a passage from Hull by the Finland Royal Mail line to Copenhagen and thence by the *ferry boat or steam* to Malmo and so to Gothenburg, Stockholm, or any other part of Sweden. Travellers by the short sea passage or so-called overland route may journey viâ Harwich and the Hook of Holland, Queenboro' and Flushing, Dover and Ostend, Dover and Calais, Folkestone and Boulogne, or even by Hamburg or Berlin and Sassnitz, Trelleborg, and Malmo. Many speak well of the service viâ Harwich or Grimsby to Esbjerg, thence by rail to Copenhagen and so to Sweden. In addition to the indispensable Baedeker,[5] visitors to Sweden should always provide themselves with the current number of the Swedish Bradshaw—"Sveriges Kommunikationer"[6]—and also the admirable guide to Sweden prepared by the Swedish

---

[1] Nos. I., II., III., IV., and V. were published in THE LANCET of April 25th (p. 1233), May 2nd (p. 1306), 16th (p. 1435), and 30th (p. 1578), and June 13th (p. 1717), 1908, respectively.

[2] The Svenska Turestföreningen issues every year a valuable illustrated handbook "Hvilo- och Kurorter i Sverige en öfversikt af Badorter, Luftkurorter, Sanatorier, Turesthotell, Pensionat, Landthem, M.M." Steps should be taken to provide an English edition of this useful manual.

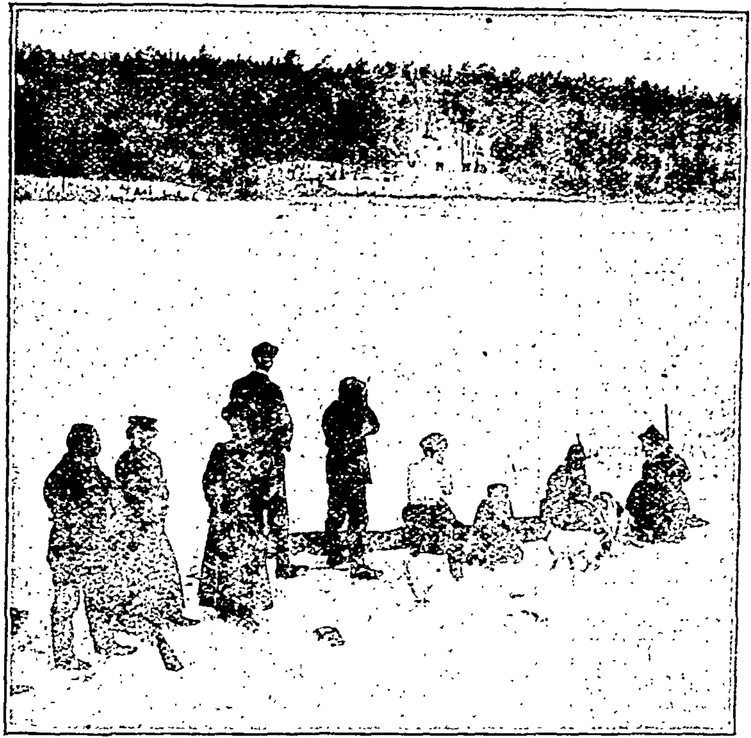
[3] For full particulars of the sailings from Hull consult booklets issued by Messrs Thomas Wilson, Sons, and Co., Hull. If this route is selected berths should be booked well in advance.

[4] For particulars consult the agents: Messrs. Phillips and Graves, 25, St. Dunstan's-hill, London, E.C., or Messrs Chr. Salvesen and Co. of Granton, Leith, and Glasgow; or the head offices of the Thule Steamship Co., Limited, Gothenburg.

[5] Norway, Sweden, and Denmark. London: Dulau and Co., 37, Soho-square.

[6] This can be obtained at all railway stations and most stationers in Sweden, price 15 ore.

FIG. 3.



Swedish winter sports.—The rifle range at Saltsjöbaden, near Stockholm.

Touring Club,[7] and the very informing handbook issued by the Swedish Tourist Traffic Society[8].

Although Swedish enterprise and effort are now opening up many centres for winter sports, and in the near future a great development of new stations may be expected, for the present and until Englishmen find themselves "at home" in Sweden I am of opinion that as a general rule they will be well advised to keep in close touch with either Stockholm or Gothenburg. There are many reasons for believing that this is the wisest course. In the present articles I shall therefore limit consideration to the districts in immediate touch with these two great centres. Experience gathered at either will speedily indicate ways and means to an exploration of less accessible districts and then it is to be expected and hoped that only those suited to undertake such incursions into new parts will attempt the experiment.[9]

STOCKHOLM AND DISTRICT.

Stockholm has been styled, not inappropriately, "the Venice of the North." It is in truth "the Paris of Scandinavia." A city of many charms, it is particularly delightful in its winter dress. Many parents take their children to Paris and Brussels for educational advantages; they would do well to remember that Stockholm has much to offer. The Royal Central Gymnastic Institute alone draws students from all parts of the world. Under the direction of Colonel V. G. Balck, a worthy successor of the great Ling, and with the assistance of Professor L. M. Törngren and Professor R. M. L. Murray, aided by Dr. A. A. Levin, Dr. S. A. Wallgren, and Lieutenant O. H. R. Hjorth, this State school for physical culture has won a unique position among the educational institutions of the world. Through the kindness of Professor Törngren I had ample opportunity of inspecting the nature and benefits of the work here being carried on, and to all desirous of seriously undertaking a scientific study of physical exercises, whether for the maintenance of health or the treatment of disease, I would commend a winter of work in this far-famed school.

This is not the place to dilate on the many attractions of Stockholm; these can be ascertained by reference to "Baedeker" and the other excellent handbooks to Sweden now available, but to the medical practitioner, and especially to the student of medico-sociological problems, Sweden's capital has many things to reveal. For the health seeker and holiday maker desirous of seeing or taking part in the winter sports, which have made Sweden distinguished throughout the world, Stockholm is one of the best centres. English visitors for a limited period will find all they can desire at the charmingly and centrally situated Grand Hotel. The winter season proper begins early in December and usually lasts up to the end of February. Skating may be enjoyed within the limits of the city. Over many of the frozen inlets of the Baltic near Stockholm ice-yachting is a fashionable and popular sport. (Fig. 1.) Skate-sailing is also an exciting recreation. Great enthusiasm is aroused by the sports meetings at which ski-jumping contests are held. (Fig. 2.) Every fourth year the "Northern Games" are held in Stockholm. The next gathering will be held in February, 1909.

Much credit is due to Colonel Balck for the systematisation and organisation of Swedish sport.[10] The bold

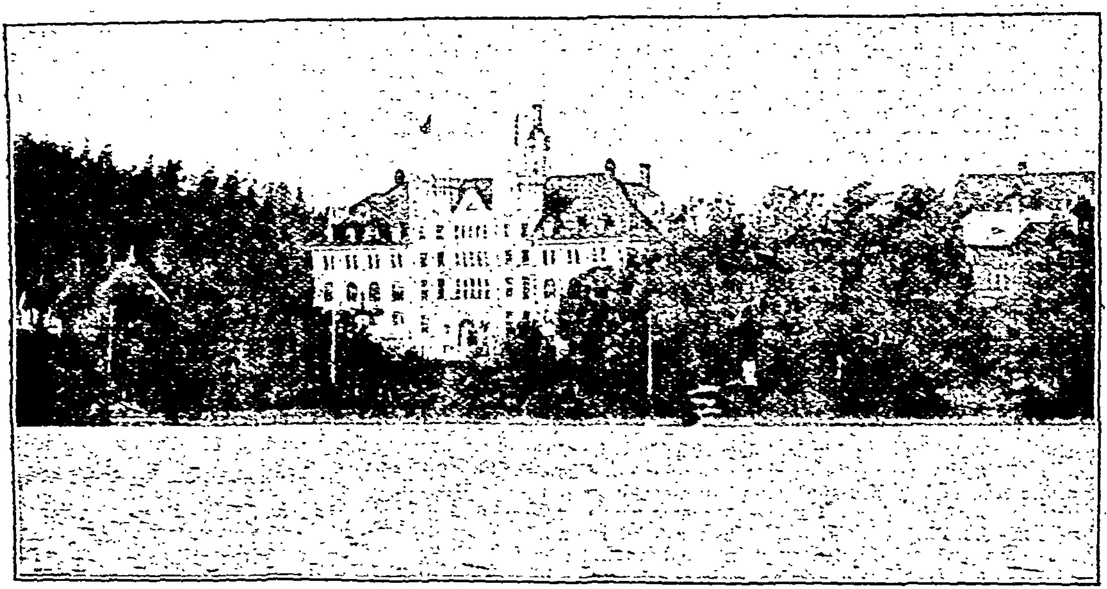
[9] Helpful suggestions will be found in "The Winter Sports Annual" for 1907–08. Edited by E. Wroughton. London: Simpkin, Marshall, and Co.

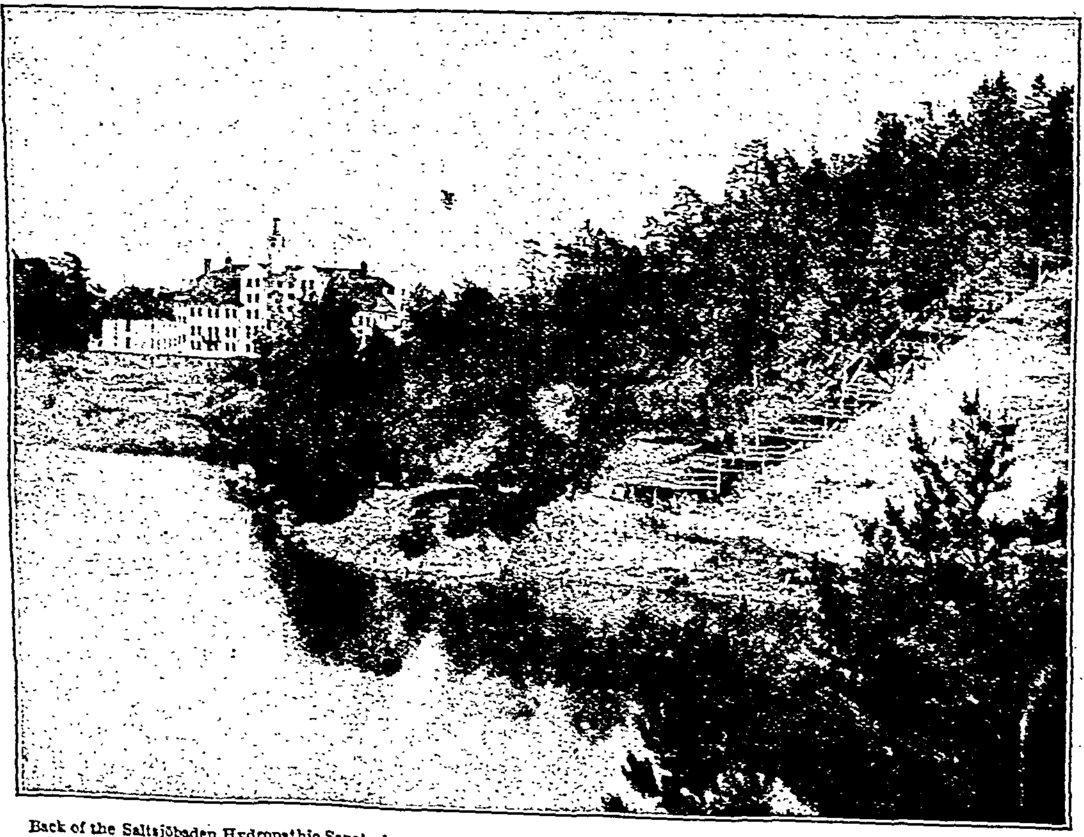
[10] Colonel Balck's chapter on "Sporting Life in Sweden" in "Sweden: A Short Handbook on Sweden's History, Industries, Social Systems, Sport, Art, Scenery, &c.," merits careful study as it affords a trustworthy and comprehensive account of present day sport in Sweden.

FIG. 5.



Saltsjöbaden Hydropathic Sanatorium and annexe on the right, overlooking the Baggensfjärd.

FIG. 6.



Back of the Saltsjöbaden Hydropathic Sanatorium, near Stockholm, showing on the right a portion of the hill slope, with stands for spectators, used in winter for the ski-jumping sports.

that winter sports now have on the youth of Sweden will be abundantly demonstrated by a visit to Stockholm's Idrottspavken. Both men and women are enthusiasts for open-air sports. The advantages of co-education, at least for Scandinavians, is fully evidenced in the conduct of winter sports and winter touring. (Fig. 3.) Ski-ing is now an important element in military education. (Fig. 4.) Societies of various kinds exist for the promotion of various forms of sport, and, as is well known, Swedes now rank with the foremost of European experts in almost all forms of physical culture and sport dependent on scientific precision and artistic skill.

SALTSJÖBADEN.

Of the several fashionable resorts in the neighbourhood of Stockholm, and forming the Swedish Riviera, Saltsjöbaden deserves the foremost place. It is situated on the beautiful Baggensfjärd, at a distance of nine miles from Stockholm. There is a good service of trains and the journey takes about half an hour. Saltsjöbaden is a charming summer resort and can then be reached by steamboat service. The place is still small. There are about 250 villas and the winter population is said to be about 1500. English visitors should make their home either at the Grand Hotel or at the Hydropathic Sanatorium.

The Grand Hotel is an imposing building with 100 visitors' rooms. It is first class in its equipment, and so far as could be ascertained in a necessarily limited inspection well managed. The *pension* terms during the winter are from kr. 45 (about £2 10*s.*) a week. Near to the hotel is an excellent sports pavilion, situated on a hill, and containing a large hall for tennis and gymnastics.

The medical visitor will be specially interested in the Saltsjöbaden Hydropathic Sanatorium. (Fig. 5.) Through the kindness of Dr. Zander I had an opportunity of fully inspecting the place. I am also indebted to Captain A. Astrand for the photographs from which the accompanying illustrations have been prepared. The hydropathic establishment was opened in 1903. It is a stone building of eight storeys of striking appearance. A special feature of the Badanstalt is the gymnasium, which is equipped with something like 40 different forms of apparatus for mechano-therapeutical applications according to the Zander method, as originally introduced by the father of the present medical director. The baths are excellent. The so-called Swedish massage bath is one of the specialities and after personal experience of the same I am prepared to testify to its pleasurable action. For many cases of chronic muscular and arthritic rheumatism it should prove of much service. Several varieties of electrical appliances are also available. In addition to the main building there is a very charming annexe. The lady superintendent spoke excellent English and everything in connexion with the establishment was such as would be likely to be acceptable to British visitors. *Pension* terms are from £2 8*s.* per week but baths and exercises are extra. Saltsjöbaden offers exceptionally fine opportunities for the conduct of winter sports and particularly skating and ice yachting. There is also an excellent ski-jump. (Fig. 6.) On an elevation overlooking the frozen bay is a most artistic and in every way charming sportsman's club-house which I visited and from which a far-extending view of exceptional beauty is obtained.

THE ORGANISATION OF THE MEDICAL PROFESSION IN FRANCE.

(FROM OUR SPECIAL COMMISSIONER.)

REACTION AGAINST THE LAW PROTECTING THE PATIENT'S RIGHT TO CHOOSE HIS MEDICAL ATTENDANT.—PROSECUTION OF MEDICAL MEN FOR ASSISTING IN MALINGERING.—A CAMPAIGN OF CALUMNY.—THE LAW DEFIED AND PATIENTS SACRIFICED FOR THE SAKE OF ECONOMY.

THE medical profession in France is at present involved in a very arduous and unequal struggle against the insurance companies. The struggle is unequal because the companies possess immense wealth and the special sort of ability needed in such a contest. It is said that their annual receipts amount to something like £10,000,000. To carry on their business they have to spend large sums in advertising and they maintain constant and intimate relations with the press. With the exception of the slender funds collected by the medical unions or syndicates the medical profession cannot be said to possess any income that can be employed for the promotion, in a collective sense, of their professional interest. Also, as it is not admissible that professional men should advertise, medical practitioners have little or no experience in the art of calling public attention to their requirements or grievances. It is only quite recently that the medical profession has acquired some experience and some capacity in the exercise of "lobby" influence and in bringing pressure to bear on the legislature. But the medical practitioners of France have still got to learn that there is a very great difference in getting a good law accepted by Parliament and in so altering established customs and traditions that this new law shall be strictly applied. Thus, in 1898 a law was enacted establishing the responsibility of employers in regard to accidents occurring among their workpeople. The medical profession then imagined that there would be a better prospect of payment when they attended an injured workman. It soon became evident, however, that the employers would insure the workers whom they employed and that the insurance companies would see to the medical and surgical treatment according to methods of their own. These methods had for practical result the reduction of the cost of medical attendance to a minimum.

The medical profession thereupon manœuvred so successfully that in 1905 they contrived to bring about an amendment of the law. According to Article 30 of this more recent enactment all workers who meet with an accident are not only at liberty to chose their own medical attendant but any person who in any way attempts to make the injured avail themselves of a medical attendant appointed by the insurance companies or recommended by the employers is to be punished. So precise and so severe was this law that not only were the grievances of the medical practitioners supposed to have been removed completely but there is a reaction, for an attempt is now made to show that grievances have arisen on the other side. The medical men, it is said, are making an abusive use of the law that was intended to protect their interests. Some months ago the lay press published sensational stories about these abuses, the whole thing being obviously engineered so as to obtain the abrogation of the law of 1905. It was no longer the employers who forced those for whom they were liable to consult the medical men whom they had themselves appointed. Now it was the medical men who not only touted but resorted to most dishonest practices so as to secure as patients injured workmen. It was even said that the medical men entered into a sort of partnership with workmen by which the latter either exaggerated their injuries or actually pretended to be hurt when there really was nothing the matter with them. With the aid of incorrect, exaggerated, or absolutely false evidence and certificates from the medical attendant the employers had to pay compensation and medical fees to which neither the patient nor his medical adviser was entitled. Thus the law enabled medical men and the employed to form partnerships for the purpose of swindling the employers or the insurance companies. It might have occurred to those who pointed out this danger to add that the immense majority of the employed are honest people, the swindler and the thief forming an exception, and that the medical profession is especially distinguished for its high sense of honour and the devotion and disinterestedness of its members. At the same time, of course, out of the 18,000 medical practitioners of France it is obvious that there must be among them a few black sheep. One black sheep has recently been caught, and, as described by your Paris correspondent, the workman was condemned to £1 fine with six months' imprisonment, while his medical attendant had to pay £20 and to go to prison for six months, while he is deprived of his right to practise medicine for five years.[1] It will be seen, therefore, that if the law of 1905 provides an opportunity for malingering and swindling the common law also provides efficient means for punishing severely such offences.

Anxious to hear what impression this disgraceful episode produced on the medical profession itself I called on Dr. Julien Noir, the general secretary of the Union of the Medical Syndicates of France. He at once pointed out two important facts. First, the rapidity with which the law had been brought to bear against medical men and the widespread publicity given to the facts by the press at large.

---

[1] THE LANCET, June 13th, 1908, p. 1725.

This observation did not apply only to the culprit whom no one is desirous of defending but more especially to five other medical men whose guilt has in no wise been demonstrated. On the simple complaint of an insurance company an investigating magistrate (*juge d'instruction*) and police commissioners are at once set to work, and within 24 hours the homes of several medical practitioners are invaded, their correspondence is taken possession of, and their records of consultations are seized and carried away. As a rule, magistrates do not act with such precipitation. When medical men complain that a quack or some company is illegally practising medicine, many months, sometimes years, pass before any legal action is taken. Dr. Noir showed me an article which he had written for the *Progrès Médical* describing a company that had largely advertised a so-called electric belt which was to restore health, youth, and strength. For two years complaints were made, but the magistrate concerned hesitated to act on behalf of the medical profession when they called upon him to enforce the law prohibiting the illegal exercise of medicine. At last a lady patient took the law into her own hands and to draw attention to the manner in which she had been treated fired several revolver shots at one of the chief offenders. The revolver shots could not be ignored and the matter was brought before the assizes. Here the lady was acquitted. Then the law on the illegal exercise of medicine was at last put in force and France is now rid of the traders and their belt. It took two years and several revolver shots before the magistracy could be persuaded to move on behalf of the medical profession, but on behalf of the insurance companies not a moment was lost.

Action has been taken against five medical men. An amnesty, however, followed shortly afterwards covering such offences and the prosecution has been dropped. One of the five medical men is most indignant and is clamouring to be prosecuted; for how otherwise is he to establish his innocence? It is a safe thing to prosecute just before an amnesty is likely to be granted, for then it will not be necessary to prove the truth of the accusation. On the other hand, it leaves on the public an evil impression that is not easily dispelled. Dr. Diverneresse, who successfully engineered the Bill on accidents through the Parliamentary Commission, has been carefully collecting a great mass of evidence which constitutes a formidable indictment against the insurance companies. For every accusation levelled against the medical profession he gives and prints full detail with names, dates, and addresses, showing that each of these offences is frequently committed by the insurance companies themselves. Actually a commission appointed by Parliament is sitting to revise the tariff of charges which medical men are entitled to make when attending a patient under the Employers' Liability Act. The principle that the patient shall have full freedom in the choice of his medical attendant is not likely to be given up by Parliament. The legislature is now fully convinced that this is a right principle. Consequently an attempt will be made to reduce the scale of payment known as the Dubief tariff to the fees given for attending paupers. The medical practitioners would then be so badly paid that it would not be worth their while to undertake this service, particularly as they know full well that some of the companies will not fail to avail themselves of any opportunity to involve them in some expensive litigation. Thus, while the injured workman will still enjoy the right to call for the services of the practitioner whom he prefers, very few such practitioners will be willing to attend. Therefore the patient would be compelled to accept the services of the medical man sent to him either by his employer or by the company in which he had been insured by his employer. Naturally medical practitioners are not going to attend well-paid workmen and others for whom provision has been made by insurance in the same manner and for the same remuneration as if they were attending poor, indigent, aged, and infirm persons who are considered by the authorities as worthy of charitable assistance.

Again, it must be borne in mind that when a general practitioner responds to the call of an injured workman he may expose himself to some hostility. The insurance companies and the employers are very influential and the medical practitioner who aids the workman to avail himself of the law of 1905 might become unpopular among those who belong to the class which is able to pay the best medical fees. The medical men who incur such risks are men of independent spirit and therefore likely to be honest and high principled. Nevertheless, if any of them did aid in some malingering swindle they would at once be denounced and expelled by the medical syndicates. At the same time, the sensational stories published by the press must not be taken for granted. For instance, a medical practitioner was accused of prescribing 70 days' rest and 183 francs worth of champagne and apollinaris water to a workman who had received a slight contusion in the abdominal region. This matter was brought to law. The judge and jury declared that the practitioner in question was a most honourable man, that the patient suffered from traumatic peritonitis, and the drug bill, which did amount to 183 francs, was, in the circumstances, quite justifiable. With the aid of the medical union the authors of this accusation are now going to be sued for damages.

The insurance companies themselves are accused of helping to bring about abuses, as it is by creating such scandals that they hope to do away with the law. They are by this law authorised to exercise a control and by refusing to do so they leave the workman and his medical attendant free to practise any form of deception. The French medical unions insist on this principle—that the person whose health is at stake should have the right to choose his medical attendant, and that the person whose purse is at stake should have the right to control the medical expenses incurred. Article 4 of the Law on Accidents grants the injured the right to choose their medical advisers, and grants the employers, who have to pay, the right to send their own medical adviser once a week to control the treatment. Also, on disputed points they may call in an expert or consultant. The medical unions have appealed to the insurance companies to appoint a joint board of control but the latter have refused this and all other methods of arbitration. Indeed, it is to be noted that the employers and the insurance companies are careful not to mention that they possess the right of control, and for not exercising this control employers were blamed on Oct. 1st, 1907, by a magistrate at St. Etienne and on March 28th, 1908, by another magistrate in the Fourth *Arrondissement* of Paris.

In regard to dishonest methods, Dr. Diverneresse recalls the case where an insurance company was ordered to pay an annuity of 227 francs to the parents of a workman who had been killed, and for two years they only gave this sum to one of the parents instead of 454 francs—that is, 227 francs to each parent. Manufacturers in the textile industries of the north are indignant at the extravagant charges made by the medical men who attend injured weavers, but the Parliamentary Commission appointed to investigate the causes of the great strike at Armentières discovered that the weavers were paid for only 133 metres, though the pieces of cloth which they wove measured in reality from 140 to 150 metres. Considering all the dishonest practices prevailing in various industries, whether it be the adulteration of food or the sizing of cotton goods and many other fraudulent devices, it is not for the heads of such manufactures and businesses to accuse the medical profession of swindling. There is a great need of independent medical men to protect the working class from the danger of being treated, not as is best for their health but in the manner which will the soonest remove them from the pension or sick allowance list. The object of the manager of a business is to reduce the expenses and to increase the profits by every possible means. If the medical men employed by these business managers do not enter into this spirit they are not likely to keep their appointments for long. But the true object of a practitioner is to do the best for his patients. It is the patients and not the shareholders of a company that the medical practitioner must serve. If a bachelor is injured and some hazardous operation might cure him completely he would not cost anything more. If the risky operation kills him there is only some £4 to pay for his funeral. But if, on the contrary, careful, patient treatment would probably save the man's life but leave him a cripple, then he remains a financial burden on the insurance company or on his employer for the rest of his days. Here, then, both the ethics of the profession and the laws of humanity are in absolute antagonism with business interests. Nor is this merely a theoretical objection. Dr. Diverneresse has the record of several cases. Thus, a workman had his hand so injured that two fingers had to be amputated, but the third finger with careful treatme might have been saved. In spite of the man's protes surgeon was forced to amputate the third finger also so as to abbreviate the duration of the treatment. There are cases in which it gives less trouble and is less expensive to amputate than to treat the wound.

Medical men have also been accused of touting so as to secure as patients injured workmen. But the employers do not tout; they coerce their employees. On March 23rd, 1908, a medical man in the employ of an insurance company was fined by the Civil Tribunal of the Seine for having, while controlling the treatment of a patient, endeavoured to make him discharge his independent medical adviser. Medical men are accused of having sent canvassers to watch outside the doors of factories and works so as to bring the injured to them. This has never been proved. It is, however, fully proved that within the factory or works, when an accident occurs the injured receive from their employers printed instructions telling them to what medical man they must go, how often they are to attend at his surgery, and in some of the printed formulas of this sort, copies of which are before me, the victim is told that if he does not go to the address given he will be considered as cured. These documents distributed to the injured altogether ignore the law. They say the victim "must go" to such or such a medical man, and in some cases add that he will lose his allowance if he does not comply with these instructions. Such instructions issued under these conditions are acts of illegal intimidation. It is no easy matter for a workman to object to his employer that the law allows him to choose his medical attendant. He may carry his point legally but he would not be very certain of retaining his employment when cured. Sometimes the injured who avail themselves of their right to select their medical attendant are taken away by sheer force. A case is given of an individual who was thus carried away in a motor carriage. Another case is thus described:—

M—— (Seine-Inférieure), December, 1907.

DEAR COLLEAGUE.—A young girl who was injured was brought to my surgery last night at 8 o'clock. I applied temporary splints and was preparing to-day a permanent dressing when I was informed that the insurance agent, without consulting anyone, had sent a carriage and had transported the injured girl to a hospital in the suburbs. The patient, a young girl who is both deaf and dumb, and without knowing the why or the wherefore, did not protest.

The law of 1898, as already explained, grants to the injured in accidents the free choice of their medical adviser. The law of 1905 punishes those who interfere with such free choice, yet the above and many other incidents prove that both these laws are constantly disregarded by employers and by insurance companies. Further, and to cover these delinquencies, as also to prepare the ground for the revocation of these laws, a campaign of scandal and calumny has been opened against the medical profession. Fortunately, although the medical profession does not, like the insurance companies, dispose of a sum amounting to £10,000,000 per annum, it has formed numerous and well-disciplined medical unions, so that it can organise some means of defence.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Dangers of Aniline.

IN the early days of the aniline dye industry its products acquired a bad name, because it was found that socks of certain aniline colours caused a great deal of suffering and annoyance from the irritation of an eczematous eruption on the legs. This occurrence was called to mind by an inquest held at Wigan on June 12th as to the death of a man, 21 years of age, named Ash, who died in the Wigan Infirmary from aniline poisoning. He was employed at the Haigh dye works, and while taking the plug out of a cask of aniline oil the contents splashed over his face and clothes. He washed himself and then continued working for half an hour. The statement was made in the cross-examination of workmen that they did not know that Ash was being gradually poisoned while wearing his wet clothes. Dr. C. G. Edmonston, the house surgeon at the infirmary, said that death was due to poisoning by aniline, which had been absorbed through the skin. Dr. T. M. Legge, the Home Office medical inspector of factories, said that the case was a most unusual one and resulted from the method of emptying the oil from the cask, instead of by means of a tap that would prevent splashing. He also told the jury that there was more danger from the absorption of aniline through the skin than from inhaling the fumes, and that if he had changed his clothes the man would probably have recovered. The verdict was "Accidental death," coupled with the recommendation to consider Dr. Legge's suggestions.

Zeal for Fresh Air.

Dr. T. H. Hayle, a member of the Rochdale education committee, has often complained of the foul air of one of the schools which he visited, and having the courage of his opinions one day deliberately smashed a window. The subcommittee was shocked and horrified, being grieved apparently to lose the vitiated air so carefully preserved by it and went so far as to pass a resolution of regret at what it termed his indiscretion and has further decided to call upon him to mend the window at his own charges. What may be the outcome of the matter lies in the future, but it ought to lead to better ventilation of the schools, and if it does Dr. Hayle may be consoled for the outlay which he may be put to by the reflection that his "indiscretion" will be very beneficial to the children of Rochdale. Years ago the ventilation of some of the Manchester schools was often very bad and to a sensitive nose the smell on entering was sickening. This is not to be wondered at when the condition of many of the homes, the stuffy unwholesome rooms, and the unwashed state of the children and their clothing are considered. All the more is it necessary that the architect should make free ventilation of the schools something that must not only be aimed at but accomplished. Education being compulsory should not entail unnecessary risk in its acquisition either for the teacher or the taught.

June 23rd.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The New Chair of Therapeutics in the University of Liverpool.

THE Senate and Council of the University of Liverpool have decided not to continue the chair of materia medica and therapeutics, until recently held by Dr. William Carter. The medical faculty considered the whole question of teaching in those subjects. After long deliberation it was decided to separate the subjects of materia medica and therapeutics. The former will in future be combined with pharmacy and will be taught by a pharmaceutical chemist specially appointed by the Council of the University. Mr. Prosper Marsden, F.C.S., the present lecturer on pharmacy, will undertake the teaching in these combined subjects. Students will take out the course in their second summer session. The subject of therapeutics will be taught by a professor who is to be a physician practising clinical medicine. He will be required to deliver a course of lectures in the summer session. Students will attend the course during their fourth year and the subject will form part of the final examination for the degree of Bachelor of Medicine. Arrangements have also been made for students to attend a course of pharmacology in their third summer session. The selection of the new professor is awaited with interest; the applications for the post were required to be forwarded to the registrar by June 20th. The chair will be unendowed, the only remuneration being derived from a share of the students' fees.

The Projected New Out-patient Department at the Liverpool Royal Infirmary.

The gift of £10,000 from the representatives of the late Mr. E. R. Bickersteth to the committee of the Royal Infirmary towards the erection of a new out-patient department, announced in THE LANCET of June 6th, p. 1657, has given an impetus to the movement for an early construction of the work, which had lagged owing to financial and other considerations. This timely gift will enable the committee to give effect to a long-felt and much-needed improvement at the Royal Infirmary. A sum of £40,000 or more will be required to carry out the project, plans of which will be completed as soon as possible. The appeal to be made by the committee for help to complete this branch of the hospital will no doubt be generously responded to.

Liverpool Students and the Medical Corps of the Territorial Force.

The meeting of students recently held to promote the success of the University section of the Army Medical Corps of the new Territorial Force was well attended and most enthusiastic. Among the speakers was the Vice-Chancellor of the University of Liverpool (Principal A. W. W. Dale), who urged students to support the movement. Dr. Alexander Gordon Gullan, the commanding officer of the section, is to be congratulated on the response already obtained. There seems now to be little doubt that the University section will be strong in numbers and distinguished for efficiency and discipline.

The late Lord Derby.

The sudden and lamentable death of the Earl of Derby, Chancellor of the University of Liverpool, removes not only a great figure in society, but a warm friend of Liverpool and her University. The late Chancellor was a great source of strength to the University, and his dignified presence and kindly speeches at the annual commencements for the conferment of degrees will be long remembered. It has become necessary, owing to his sad demise, to postpone the conferment of honorary degrees, and the conferring of ordinary degrees will, on this occasion, be a private function, unattended with the usual *éclat*. The University of Liverpool has suffered much during the last 12 months from death and now it has lost, perhaps, its most influential supporter.

NEWCASTLE-UPON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

University of Durham Bill, 1908.

THE University of Durham Bill was read a second time on Tuesday in last week and referred to a standing committee. The object of the Bill, as has already been pointed out in these columns, is to reconstitute the University of Durham and for that purpose to appoint a statutory commission. The Bill provides for the following persons to act as the Commissioners—namely, the Duke of Northumberland; the Bishop of Exeter; Lord Barnard; Sir Francis Mowatt, sometime Permanent Secretary of the Treasury; Sir William Church, sometime President of the Royal College of Physicians of London; Mr. J. Scott Fox, K.C., Chancellor of the County Palatine of Durham; the Rev. Dr. J. R. Magrath, sometime Vice-Chancellor of the University of Oxford; and Mr. J. Larmor, F.R.S., Lucasian Professor of Mathematics in the University of Cambridge. These names constitute a very able and experienced body of men whose appointment will inspire confidence in those who have interests at stake that these various interests will be sympathetically considered and fairly treated. It is hoped that the final stages of the Bill will be so accelerated that it may receive the Royal Assent and become law with as little delay as possible. Under the Bill the University is to consist of three parts: the Durham division, chiefly theological, and the Newcastle division, comprising the College of Medicine, and Armstrong College. Each of these three parts will have its own representatives on the Senate. And while the principle of the Bill has been cordially received, the question of the amount of representation to be awarded to the various parties interested has evoked a very considerable amount of discussion. The College of Medicine, while approving the principle of the Bill, reserved to itself the right to make representations before the Commissioners on the subject of the number of representatives it should have on the Senate. To what extent each interested body should receive representation is, of course, purely a matter for the Commissioners. But with regard to the College of Medicine it may be here pointed out that there are matters in the constitution of the College and in the provision for teaching pathology and physiology which will certainly handicap its representatives when they appear before the Commissioners to ask for larger proportional representation on the Senate of the reconstituted University.

Degrees in Dental Surgery.

The Council of the College of Medicine has decided to grant degrees in Dental Surgery—viz., a Bachelor's degree (B.D.S.) and a Master's degree (M.D.S.) This is a concession which has been asked on several occasions in the past. The whole of the work required for the final examinations of the Royal Colleges of Surgeons of England and Edinburgh can be done in Newcastle, but up to the present time there has been no local examining body.

Motor-Cars for Medical Men.

An interesting meeting was recently held at Hexham in connexion with the Northern branch of the British Medical Association at which a number of medical men gave the results of their experiences of the use of motor-cars for professional purposes. As regards cost there was, as was only to be expected, great divergence of opinion. The cost of running a car appears to depend very much upon the mechanical propensities of the owner. Ignoring wages and depreciation the cost appears to work out at about 3*d.* to 4*d.* per mile when treated with ordinary care, though this figure may be reduced considerably in the case of a man who has a liking for mechanical instruments. Half the running expenses is spent on tyres. As regards depreciation, it would seem to be best to buy a good car and to sell after two years' use while it is still in good condition and running well. On the whole, the discussion under the head of cost seemed to resolve itself into the statement that a car costs much the same as a carriage and pair of horses, and in this part of the country that is generally taken to represent from £170 to £200 per annum. Where a man's work lies entirely within a city—as, for instance, Newcastle or Gateshead—the view was expressed that a car is something of a luxury; for instance, one speaker stated that while in the country with but few stops he could run 40 miles on a gallon of petrol he found he could only cover 16 miles in town, owing to frequent stoppages at short distances for one purpose or another. On the other hand, where one's work was not strictly limited to a town but involved visits to distant outlying places the general opinion was most emphatic that a motor-car was a *sine quâ non*, especially in a county like Northumberland, where trains were at all times few and in many places did not run on Sundays. But over and above the question of cost a great deal was said in favour of the motor-car in the practice of medicine. Many men seemed to find a great deal of pleasure in driving their cars and found that their journeys were relieved of the great monotony which was such a serious factor in the pre-motor-car days. A motor-car gives a new pleasure to one's rounds, it prevents brooding over serious cases, robs night-work of a great deal of its former terrors, and in the country enables one to get one's work done much more quickly, setting free for other things some three or four hours a day which were formerly spent in travelling about.

June 23rd.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Proposed Isolation Hospital.

AT a meeting of the Dolgelley urban council (North Wales) on June 19th Mr. A. E. Hughes moved that a resolution passed on Nov. 15th, 1907, directing the sanitary committee to obtain a piece of land outside the urban area and to erect an isolation hospital thereon should be rescinded. He declared that the majority of the ratepayers were against the hospital and that he was returned at the last election as an opponent to the movement. Medical men were divided on the question and it was contended that when patients mixed in hospitals slight cases became malignant. Another difficulty was that patients could not be removed without magisterial orders. No town in the county had been so free from infectious diseases during the year. It was explained that the council had passed several resolution in favour of the hospital, but efforts made to find a site had been futile. So far it had done its duty and it was felt that if an outbreak occurred after rescinding the resolution it would be in a false position and could give no answer to the demands of the Local Government Board. Other members while advocating the principle of a hospital believed a small cottage would be sufficient without erecting an expensive and isolated hospital. On a division there was equal voting and the motion was declared lost.

The Winsley Sanatorium.

A Local Government Board inquiry was held in Bristol recently relative to the application of the Bristol city council to make a further capital grant of £1000 to the Winsley Sanatorium.

A County Medical Officer of Health for Devon.

At a meeting of the Devon county council held o

June 18th, under the presidency of Earl Fortescue, it was decided to appoint a medical officer of health for the county at a salary of £600 per annum, with an additional £200 a year for travelling expenses and clerical assistance. He will be required to supervise the medical inspection of school children in elementary schools and also to undertake the supervision of midwives. At the same meeting the council decided to expend £150 in the award of scholarships for the training of midwives to candidates recommended by the Devon County Nursing Association.

An Incorrigible Offender.

At Exeter on June 19th Richard Rogers had five summonses returnable against him under the Sale of Food and Drugs Act for selling margarine as butter and for selling margarine not labelled as such. The defendant had been convicted for similar offences at Exmouth, Dartmouth, Torquay, and also at Exeter. The magistrates sentenced him to four months' imprisonment, with hard labour.

June 23rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Physicians of Edinburgh: Election of President.

AT an extraordinary meeting of the Royal College of Physicians of Edinburgh held on June 23rd, Dr. John Playfair, the Vice-President of the College, was elected President for the remainder of the current year of office, in place of the late Dr. C. E. Underhill.

Professor Annandale's Successor in the Chair of Clinical Surgery in Edinburgh.

The Secretary for Scotland has appointed Mr. Francis M. Caird to the Regius chair of clinical surgery in the University of Edinburgh. Mr. Caird is a graduate of Edinburgh University of 1877 and an F.R.C.S. of Edinburgh of 1880. In his early years he went through the training that so many surgeons have had—namely, of teaching and demonstrating anatomy and of acting as assistant to the professor of surgery. For many years he has been a most successful and popular lecturer on systematic surgery in the extra-mural school. His class was always largely attended and no one in Edinburgh did more for the teaching of surgery than he did. In addition to many papers he is joint author with Mr. C. W. Cathcart of a "Students' Atlas of Bones and Ligaments" and "A Surgical Handbook." He has been for some years a surgeon to the Royal Infirmary and is well-known as one of the pioneers in abdominal surgery in Edinburgh. There was a large field for the Secretary for Scotland to select from, and any of the applicants would have filled the chair with success, but it is felt that no one had done more for surgery than the successful applicant.

Appointment of Sir Henry D. Littlejohn's Successor.

The Edinburgh town council has appointed Dr. Alfred Maxwell Williamson to be medical officer of health of the city of Edinburgh in succession to Sir Henry D. Littlejohn. Dr. Williamson is an M.B. of Edinburgh of 1888 and took the M.D. degree in 1899. He is a B.Sc. in public health of 1890. For a number of years he has held the office of chief sanitary and markets inspector for the city of Edinburgh. He is known to have taken a very active interest in his work and the town council has shown its appreciation by promoting him to the vacant office.

Changes at the Edinburgh Royal Infirmary.

The managers of the Edinburgh Royal Infirmary have decided to form an additional surgical charge. At present three wards are allotted to the care of the professor of clinical surgery and three to the senior ordinary surgeon. The managers have decided to take one ward away from each, thereby providing the necessary number of beds for an additional charge. This gives practically an equal number of beds to each surgeon. This change, together with Mr. Caird's elevation from being an ordinary surgeon to being a professor, makes two vacancies on the full staff which will be filled by the elevation of Mr. David Wallace and Mr. H. Alexis Thomson from assistant to full surgeons and will make two openings for assistant surgeons. The changes will take place before the beginning of the winter session. It may also be mentioned that recently Dr. John Dixon Comrie was appointed an assistant pathologist to the Infirmary in room of Mr. Henry Wade who was appointed an assistant surgeon to Leith Hospital.

A Noteworthy Compensation Case.

An interesting decision has just been recorded at Hawick by Sheriff Laing in a case where the pursuer asked for compensation from a firm of contractors for the death of his son from the bursting of a blood-vessel while working at a winch. It was argued on behalf of the pursuer that it had been proved that while the deceased was winding up bricks a scaffold with a number of men and bricks on it collapsed in his immediate vicinity. The deceased made a special effort to wind up the winch so as to allow him to help at the scaffold, and in this way he strained himself, causing the bursting of a blood-vessel from which he died shortly after. This it was contended was an accident within the meaning of the Workmen's Compensation Act of 1906. It was contended for the defenders that compensation was only due in the case of a man who in ordinary health strained himself in the reasonable performance of his duties and that, as in this case, where a man suffering from disease had his life shortened by the acceleration of the disease by accident no compensation was due under the Act. It had been proved, they said, that the deceased had, unknown to himself, been suffering for a year previously from phthisis. The Sheriff found the pursuer entitled to compensation from defenders in respect that the death of his son was due to personal injury by an accident and arising out of his employment. He assessed the sum at £75, with expenses.

University of Glasgow: Chair of Clinical Medicine.

It is announced that the University Court will proceed to make an appointment to this chair on July 9th or on an early date thereafter. All further information may be had from the secretary to the Court.

Montrose Royal Asylum and Infirmary Board: Annual Meeting.

The annual meeting of the Montrose Royal Asylum and Infirmary Board was held in the town buildings, Montrose, on June 9th. Dr. J. G. Havelock, physician superintendent, presented his annual report which showed that moral causes, such as domestic troubles, business worries, &c., accounted for about 40 of the cases of insanity, adolescence for 12, intemperance for nine, change of life for 12, influenza for eight, and old age for 14. Hereditary influence was the chief predisposing cause. Mention of one case was specially made as it illustrated this point in a striking manner. Four adult members of a family living in a remote part of Shetland—three sisters and one brother—were all sent to the asylum in the course of a fortnight. They were most respectable, industrious people, abstainers, and living in comfortable circumstances. The sudden death of a relative was the exciting cause. One after another they were seized with acute melancholia, and on inquiring into the family history Dr. Havelock found that there was a strong hereditary taint and that several of their relatives were in the asylum or had been in former years. Happily, two of the sisters had been discharged as recovered and the brother was progressing satisfactorily.

June 23rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Annual Meeting of the Irish Medical Association.

LAST week I sent a note of the proceedings at the annual meeting of the Irish Medical Association which was held in the Royal College of Surgeons on June 10th, under the chairmanship of Mr. J. S. McArdle, the past President. I send you now a fuller abstract of the report which was presented by the honorary secretary, Dr. Thomas Donnelly, at the meeting. It states that during the past year 26 meetings had been held. The deaths of 13 members had been notified, 18 resignations accepted, and 11 new members elected, leaving a roll of members numbering 726 on Dec. 31st, 1907. As the question had been raised as to whether medical officers of workhouses are entitled to professional fees for giving expert evidence and for making post-mortem examinations, it had been considered advisable to obtain the opinion of counsel. The opinion received was to the effect that the Coroners Act, Sec. 36, deprived all medical officers of public hospitals and infirmaries of fees for inquests upon patients to whom it was a part of their duty to give medical aid. Counsel was further of opinion that this deprivation does not extend to an inmate of the workhouse and who had died in it. A deputation from the council waited upon the Local Government Board in reference to fees payable under the Labourers Act (1906). The reply pointed out that the Act would be more extensive in operation than the earlier Acts had been and that consequently a larger sum would be obtained in fees. For this reason the Board could not see its way to increase the fee formerly sanctioned. This Act came into force on July 1st and it includes within its scope a large number of employees who could on various grounds find it necessary to requisition the services of the medical practitioner, who, it must be remembered, cannot be compelled to give his services or to issue certificates gratuitously. The council had taken the precaution of advising medical men through the public press not to give certificates until payment had been made or guaranteed. The duties of certifying surgeons will obviously be increased under the Workmen's Compensation Act (1906) and rules dealing with their duties and powers have recently been formulated by the Home Secretary with the Treasury. The opinion of the law agent was obtained in this connexion and a deputation had waited on the Local Government Board for the purpose of pointing out the hardship of the rule compelling dispensary medical officers to occupy the position of certifying surgeons. The council had considered the Order of the Local Government Board of May 13th, 1902, disqualifying medical men from acting on public boards: members were reminded that this matter had been dealt with in 1899, in which year the Local Government Board had issued (Jan. 17th) a sealed Order debarring any paid officer engaged in the administration of Poor-law relief from acting as a county councillor. The opinion of senior counsel had been obtained, who advised that: "The question of the validity of the Order of the Local Government Board depends upon the extent of their powers. The approval of the Lord Lieutenant does not make a bad Order good. I think, on the whole, that the Order imposes a collateral disability on the medical officers as individuals, and does not define or regulate their duties as medical officers. When it was desired to impose such a disability, it was done by statute. I think, therefore, the Order is *ultra vires*. However, as it purports to be made under the statutory powers of the Commissioners by Sec. 114 of 1 & 2 Vic., Cap. 56, every Order made under the powers of the Act is good until quashed on *certiorari*." This Order of 1899 was cancelled by the Local Government Board in 1902, when the present Order was issued. There is no valid reason why a medical man who does not hold any paid office under a public board should be disqualified from acting on it. An extraordinary general meeting of the association was held immediately after the general meeting of June 5th, 1907, for the purpose of considering and drafting new articles of association. It was then decided to refer the whole question back to the reorganisation committee and to report at a future meeting. A special general meeting was convened for Nov. 28th, but the requisite three-fourths majority was not obtained for a by-law proposed. The audited accounts of last year were submitted and showed that the balance of law costs for the years 1905–06, amounting to £297 17*s*. 2*d*., with cost of taxation £10 18*s*. 5*d*., making a total of £308 15*s*. 7*d*., have now been paid. Two years' subscriptions are owing by 54 members, 104 members owe one year's subscription, and one member owes 10*s*. 6*d*., making an outstanding total of £223 2*s*. 6*d*.

Dublin Throat and Ear Hospital: Question of Amalgamation.

An application was made in the Chancery Division of the Four Courts before the Master of the Rolls on June 15th by the trustees of the Dublin Throat and Ear Hospital to approve a scheme to be settled at chambers under an order of the court which directed that the regulation of the funds and property of the hospital should be dealt with by amalgamation or affiliation of the hospital with some institution of a similar character, with liberty to the trustees to dispose of the house in Hume-street, in which the work of the hospital had been carried on. Counsel said that the trustees had been able to effect an assignment of the house with the sanction of the landlord. The funds dealt with by the scheme were £246 Consols and £25 cash; and it was proposed to transfer the property to the Adelaide Hospital. Sir Augustine Baker (solicitor), speaking from an individual capacity as a member of the board of the Royal Victoria Eye and Ear Hospital, stated that at a meeting at which he was present some years ago it had been agreed that the fund should be transferred to the Royal Victoria Hospital, it being recognised then, as now, that it was the only hospital that really dedicated all its funds to this particular branch of surgery. He replied in the affirmative to the query of the Master of the Rolls as to whether the hospital referred to treated affections of the throat. It was replied that this was the first notice of an application on behalf of the Royal Victoria Hospital, the main business of which was the treatment of the eye. The Master of the Rolls said that he would give Sir Augustine Baker an opportunity of putting forward a claim on behalf of the Royal Victoria Hospital. If that institution gave relief in cases of throat diseases, as well as of those of the eye and ear, it seemed clear that the money ought to go there.

Royal Hospital for Incurables.

The monthly meeting of the Royal Hospital for Incurables, Donnybrook, was held on June 12th. The chair was occupied by Mr. W. J. Fry. The proceedings of the last meeting of the committee, with those of the visiting and finance committees, were read, confirmed, and signed. The MS. book containing "Remarks by Visiting Governors" was shown and the following minute was read to the meeting:—

> I visited the hospital and went through the wards, conversed with many of the patients, nearly all of whom seemed to be grateful and happy. It is unnecessary to say that everything was in perfect order.
> May 30th, 1908. (Signed) R. H. A. McComas.

The number of patients in the house was 208: 85 males and 123 females. A large number of voluntary contributions, of amount varying from £5 downwards, were acknowledged with expressions of grateful thanks. Altogether, the institution, which is doing excellent work in the way of alleviation of hopeless disease, proves to be in a highly satisfactory state.

The Upkeep of the Insane.

The subject of the upkeep of lunatics, which is becoming of increasing importance in Ireland, was discussed at the meeting of the joint committee of the Richmond lunatic asylum on May 21st. At the opening of the debate it was pointed out that: "In view of the responsibility which has been imposed on us of the care of 600 pauper lunatics in the workhouse of this district and the capital expenditure such a duty involves, it would become a very serious matter for the councils charged with the upkeep of this asylum if, as far as the payment of grants for lunatics is concerned, it should be proved the local taxation account has reached the limits of its resources, in which event the district would have to bear not alone the charge of an additional expenditure of capital but the entire cost of maintenance as well of this large accession to our number of patients." By the friendly exertions of Mr. D. J. Cogan, who was then in Parliament, publication was secured last year of a full account of the transactions for the seven years from April, 1889, to March, 1906, and the audited account for 1906–07 was issued last month. A compilation from this return was before the meeting for consideration. An examination of the data led to the conclusion that the resources of the local taxation account are insufficient to meet any additional demands, "and, worse still, that it is inevitable that the grant already paid from it in relief of the maintenance of lunatics must, in the near future, be considerably reduced." It was pointed out that during the last four years the income had become stationary at £291,000, the fluctuations not exceeding £100 or £200 a year; while, on the other hand, the annual expenditure has risen from £251,000 in 1899 to £306,000 in 1906, "notwithstanding the fact that the payments in relief of Poor-law union expenditure have been restricted by Section 6 of the 1902 Act to an amount not exceeding that paid during 1901–02." Further examination led to the conclusion that unless additional revenue be provided the annual expenditure of the local taxation account must, in the immediate future, be reduced to an amount some £30,000 less than the sum which the local bodies at present receive. It was suggested that the assistance of the Irish Members of Parliament, and even that of the Local Government Board, should be sought through Sir Henry Robinson. One speaker thought that they should press for an increase of the capitation grant.

Inspection of Dairies.

The new Order regarding inspection of dairies, cowsheds, and milkshops which came into force on May 1st has had, a course, the immediate effect of very considerably swelling the sum total of the duties of the medical officers of health. In the great majority of the districts the sanitary sub-officers to whom the duty of insuring the carrying out of the provisions of the new Order has been intrusted are to be known as dairy inspectors. Additional officers may also be appointed with the approval of the Local Government Board, which body has issued a circular to the various sanitary authorities suggesting the desirability of appointing veterinary surgeons. But the instructions of the Order on this head are not definite or final. They do not appear to secure for the medical officer of health any official position or controlling status, although the ultimate success of its aim must necessarily depend on his supervision. It is unlikely that veterinary surgeons will be made to replace the present sanitary sub-officers as dairy inspectors, with the merely nominal salaries which the latter have been receiving, even in the largest districts. And it is important to members of the medical profession to ascertain at the earliest possible date whether the health officers are to receive additional salaries under the new conditions. The only suggestion of increase of income with increase of duty seems to be that of Article 22 that every registered dairyman or cowkeeper will be prevented from occupying a new cowshed until he has obtained from the medical officer of health a certificate of the fitness of the building and its compliance with the regulations as to light, ventilation, drainage, water-supply, &c. For the work and labour of the inspection required before the preparation of the certificate and the issuing of the latter a reasonable fee is attached. The Order, as was to be expected, has met with some opposition. At a meeting of the Aghadowey Creamery, with Dr. H. S. Morrison, the President, in the chair, a resolution was passed to the effect that those present, representing the Aghadowey Coöperative Creamery and the 700 farmers who form its shareholders and milk-suppliers, are of opinion that the inclusion of the suppliers in the Dairies and Cowsheds Order is unnecessary:—

> (1) because all our milk is sterilised before it is manufactured; (2) it is not sold as milk, but only as butter and cream; (3) practical experience has shown that although proper sanitation is necessary in byres, and very desirable, nevertheless the standard fixed by the recent Order, if insisted upon, will be ruinous to the farmers of Ireland; (4) we desire to express our opinion that this Order should only apply to dairies that systematically sell milk in towns; (5) that the sub sanitary officer of each district is quite equal to the task of pointing out any defect that requires a remedy in all cases except dairies; (6) we desire to express our thanks to the Coleraine rural council for their resistance to this Order, which, in our opinion, is vexatious, and except in the cases mentioned unnecessary, and we call upon every district council in Ireland to give their assistance in this matter.

At a meeting of the Belfast public health committee held on June 11th the executive sanitary officer reported that at the summons court on June 9th two persons were fined for breaches of the Dairies, Cowsheds, and Milkshops (Ireland) Order, 1908.

The Belfast Board of Guardians.

The Local Government Board has written to the board of guardians of Belfast after the recent biennial elections requesting that body to proceed to the election of a lady superintendent nurse. The whole matter will be considered at the next meeting of the board, of which a medical man, Mr. J. S. Bryars, has been elected the new chairman.

Royal Victoria Hospital, Belfast.

Hospital Saturday has this year yielded, up to the present, a sum of £837 for the Royal Victoria Hospital, which is only 5 per cent. less than last year, which is not to be wondered at considering the extraordinary dulness of the times in Belfast. It is expected, however, that some more money will be available from collections in the smaller towns in the neighbourhood of Belfast.

Ulster Medical Society.

At a meeting of the Ulster Medical Society held on June 18th, Dr. T. S. Kirk, surgeon to the Royal Victoria Hospital, was elected President for the ensuing year.

June 23rd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The French Society for the Study of Cancer.

THE late Professor Poirier shortly before his untimely death proposed to coördinate the study of cancer in France, but his illness prevented him from carrying out his intention. This project, which is of the utmost value in a country where cancer claims 13,000 victims every year, has been now taken up, and for more than a year a large body of scientific men have been working to put it into execution. The result is that the French Association for the Study of Cancer has been organised with honorary and corresponding members and more than 60 active members. Its officers are Professor Bouchard, president; M. Barrier, director of the Alfort School, vice-president; M. Pierre Delbet, general secretary; M. Ledoux-Lebard, secretary of meetings; M. Henri de Rothschild, treasurer; and Professor Petit, of the Alfort School, librarian. The association intends to organise laboratories and to give subsidies and prizes for research work on malignant tumours. As the etiological factors of cancer are of prime importance the association intends to send out a circular inquiry form to all the medical and veterinary practitioners in France which will contain spaces for the supply of statistics, and the replies should give accurate information of the regions where cancer rages with particular severity. At present more than half the victims of the disease only seek medical advice when it is too late to do anything for them; since this often comes from ignorance of apparently insignificant symptoms which mark the onset of cancer, the association will also concern itself with the education of the public. The meetings will be held monthly.

The Sale of Oysters.

The Prefect of Police has just issued an order regulating the sale of oysters under the advice of the Council of Public Health. In future it will be illegal to expose for sale or to sell for food oysters unless their shells have been first cleaned of all animal or vegetable matter or other débris by brushing or some other means. Vendors of oysters may only employ to soak or to sprinkle them water suitable for the public drinking-supply, with salt added in the requisite proportion. It is especially forbidden to use for this purpose salt which has been employed for preserving fish or other commodities. Salesmen who open the oysters themselves before delivering them must only employ instruments for the purpose which are kept constantly clean; they are not allowed to wash oysters after opening them; and they must see that the oysters are not exposed to any dirt. Any breach of these regulations will be a penal offence.

A Case of Fatal Ascending Paralysis following on Antirabic Treatment.

M. Babès and M. Mironesco communicated the notes of this case to the Biological Society on June 6th. The patient was a woman, 40 years of age, who had been bitten by a rabid dog and submitted to treatment six days later. At the end of a fortnight of inoculations of the lesser strength the course was interrupted by the appearance of symptoms of paralysis of the lower limbs but without any symptoms of hydrophobia. The paralysis took an ascending form and rapidly proved fatal. At the necropsy œdema of the meninges and of the brain with softening of the dorsal and lumbar segments of the cord was discovered. Portions of the bulb and cord injected into rabbits did not prove fatal to them. Microscopical examination of the cord showed widely spread lesions in both white and grey matter; irritative lesions were found in the bulb and the brain but no Negri's corpuscles were demonstrated. The case was not one of paralytic rabies and it would seem that this condition has been confused hitherto with cases of rabid intoxication more or less severe.

The French Society of Hygiene and the Fishermen.

The French Society of Hygiene intends to hold a Congress this year dealing with the dwellings of sea fishermen in a district to be determined by the delegates with the idea of improving the hygienic and moral environment of the "toilers of the deep." The work of the Congress will be in two sections. The first will deal with the statistics of births, deaths, and preventable diseases, the details of certain houses occupied by the fishermen and their families, the cost of such dwellings, and their sanitary arrangements with reference to the supply of water for drinking and household needs and the drainage of rain and slop-water. The second section will be concerned with the method of improving the hygienic conditions of such dwellings and of such settlements and villages as stand in need of it and with the construction of new suburbs near over-populous maritime towns. Several prizes, including a gold medal worth 200 francs, will be awarded at the Congress.

A Home of Rest for the Aged.

At last week's sitting of the supreme council of the Public Assistance M. Mesureur, the Director, announced that he had received information of the bequest to the Assistance by a generous benefactress of certain property, including a farm and a garden at Arcueil and a sum of 10,000 francs. By the terms of the will this legacy must be devoted to the establishment of a home of rest for old people of both sexes who must be at least 60 years of age and French citizens and must never have been adjudged guilty of any offence; in choosing them no political or religious distinctions are to be made. The institution is to be known by the name of the Cousin de Méricourt et Besson Home of Rest and is to be served by the sisters of St. Vincent. This condition is absolute and non-compliance with it will render the bequest null and void, as will failure to open the home within five years of the death of the testatrix.

"Pathomimia."

At a meeting of the Academy of Medicine on June 9th Professor Dieulafoy described the extraordinary case of a man, 30 years of age, who two and a half years ago began to suffer from gangrenous lesions on his left arm and forearm. He consulted several medical men and received different opinions—trophic disorders, neuritis, myelitis, and hysteria being suggested in turn. He underwent an operation for the stretching of the nerves of the left arm, but as the sloughs continued this was amputated at the upper third. A few months later gangrenous patches made their appearance on the right arm and quite recently large sloughs have formed on the left foot. Professor Dieulafoy has eliminated the diagnoses of syphilitic or tuberculous ulcerations or a spinal trophic affection, and he denies absolutely the possibility of a hysterical tropho-neurosis. He came to the conclusion that the lesions were self-inflicted both on account of the rapidity with which the sloughs formed and of their resemblance to lesions made by cauterising with Vienna paste. He considered that the sloughs had been caused by caustic potash, and the patient, after being kept under strict observation, was induced at a psychological moment to confirm this diagnosis. Professor Dieulafoy set himself to study his mental condition. He declares that the man produced the sloughs and submitted his arm to amputation in response to an uncontrollable impulse with no intention of fraud or of getting anything by his action. Professor Dieulafoy designates this morbid mental state as "pathomimia."

A Curious Observation upon Birds.

On June 9th M. Jean de la Riboisière communicated to the Academy of Science the results of a series of organometric researches which he has made upon a number of birds. These investigations have convinced him that a very definite organic relationship exists in birds between the quantity of plumage that they possess and the bulk of their liver and kidney substance. In every species he found that individuals with the largest livers had the fewest feathers and *vice versâ*, and he suggests, surely with some boldness, that the plumage of birds is capable of exercising a supplementary hepatic function.

June 22nd.

INDIA.

(FROM OUR OWN CORRESPONDENTS.)

The Principal Medical Officer in India.

Surgeon-General W. L. Gubbins, C.B., M.V.O., Principal Medical Officer His Majesty's Forces in India, sails from Bombay on June 6th to take up his new appointment as Deputy Director-General at the War Office. Surgeon-General F. W. Trevor, C B., V.H.S., at present principal medical officer of the Poona Division, will succeed him at Simla. Surgeon-General Gubbins held the appointment of Assistant Director-General at the War Office in 1897, whence he went to the South African war as principal medical officer of the 6th Division and afterwards as principal medical officer at Pretoria, being mentioned in despatches and specially promoted colonel. As principal medical officer of the London District in 1902 he had supreme charge of the medical arrangements in connexion with His Majesty's Coronation and received the M.V.O. in recognition of his services. From London he passed by special selection to India as principal medical officer, Western (Bombay) Command, and from this to Eastern (Bengal) Command, and finally was specially selected as chief of the military medical service in India. As principal medical officer on Lord Kitchener's staff in India he has held this appointment for two years. During his tenure of office at Simla Surgeon-General Gubbins has initiated and introduced many changes. The better conditions and supervision of Queen Alexandra's Military Nursing Service for India was one of the first matters to receive attention. Improvements were introduced as regards station and family hospitals and questions affecting the health, eyesight, &c., of the young children of soldiers were the subject of special inquiry. Committees having Surgeon-General Gubbins as President were appointed by the Government of India and His Excellency the Commander-in-Chief to examine and to advise on nearly every subject of military medical importance affecting India specially—enteric fever, trooping arrangements for invalids, field hospitals, mobilisation stores, the better treatment of venereal diseases, station and family hospitals, conditions to better troops in barracks, and so on. Ten divisional sanitary officers each possessing a D.P.H. diploma were appointed to the ten divisions of the army in India with an eleventh at army headquarters as sanitary staff officer to the principal medical officer. Besides this, each brigade laboratory had specialists in bacteriology appointed to them for research work in enteric, malarial, and other fevers. This organisation of preventive medicine in the army of India may be regarded as the most valuable and permanent record of the work effected during the tenure of office of Surgeon-General Gubbins and its fruits will be apparent to anyone studying the statistics of disease in the medical reports of the army of India. Another far-reaching change introduced was the creation of independent principal medical officers of divisions with military medical officer for their staff officer, and the wisdom of the step has been very manifest in the recent mobilisation for the frontier, which at one time assumed considerable proportions, as had the Afghans not stopped when they did a general mobilisation must have occurred. In bidding good-bye to India Surgeon-General Gubbins carries the best wishes for his future not only of the army but also of many friends from the other services, and he leaves with the satisfaction of knowing that he has left his work in order and ready for his successor to carry on smoothly.

Pasteur Institute of Kasauli.

In the Pasteur Institute of India at Kasauli during the last six years for which statistics are available 4052 persons have been treated, with a mortality of 35—i.e., 0·8 per cent. If, however, we take the statistics of Europeans and natives of India separately we get the following figures: (*a*) Europeans treated, 1527; failures 2, or 0·13 per cent.; and (*b*) natives of India treated, 2555; failures 33, or 1·2 per cent. The difference between the statistics for Europeans and those for Indians is very marked, the much greater percentage of failures amongst the latter being without doubt due to the facts (*a*) that the majority are bitten on the bare skin; (*b*) that many of them are bitten by jackals and wolves; and (*c*) that Indians delay much longer in coming for treatment than Europeans.

Cholera at Peshawar.

The principal anxiety in connexion with the Mohmand Field Force has been in respect of an outbreak of cholera amongst our units at several points. The disease is not uncommon in the early summer in the Peshawar Valley and it frequently takes an epidemic form. The Royal Munster Fusiliers when in camp near Abazai suffered severely and the Northumberland Fusiliers also had their quota of cases. Among sepoys and followers, too, some deaths occurred. But cholera is now rapidly abating and the Field Force itself is not likely to be affected. The army medical authorities have taken the strictest measures to secure a clean bill of health on the march. The regiments belonging to the brigades mobilised in connexion with the Mohmand Field Force that have been infected with cholera have returned from the camps in which they were segregated. The 5th Fusiliers marched into Peshawar on May 20th and occupied their own barracks, the 3rd Mountain Battery which was located in a portion of the Fusiliers' lines moving out into a camp in the cantonment. The 4th Gurkhas have also gone into camp. It is evident that the measures taken to protect the Munster Fusiliers from further infection have been successful. No further cases have occurred and it is hoped that they are now free and will return shortly to Peshawar. The epidemic in this regiment has been severe. There have been 42 cases with 28 deaths, all amongst the rank-and-file. Cholera in Peshawar city also shows signs of abatement. In all, there have been some 200 cases in the city. A few cases are occurring here and there in the cantonment, but there are at present no signs of the disease assuming alarming proportions. A few cases have occurred amongst the troops towards the Khyber. The Mohmand Field Force has benefited by the unexpected cold wave, due to thunderstorms and hail, which passed over the Punjab and the Western Himalaya region, but the summer has now fully set in very suddenly.

Cholera at the Coal-fields.

Cholera is very bad in the coal district just now. Mr. Haffkine has gone to Jherria to perform cholera inoculations, the labour at the coal mines being seriously affected. Only those obliged to travel across the country over the fields and nullahs from colliery to colliery are able to gauge the force and extent of the epidemic which is raging from Asansol to Jherria. One by one the collieries are shutting down for want of labour, as the miners fly from the scourge. At one place 80 deaths are reported in three days. Many house servants have succumbed. The oldest residents have not known a severer outbreak or one more general than this. Dead bodies are said to be lying in dry nullahs and fields left to be devoured by vultures and dogs. In certain tracts the air is offensive to breathe. No signs of rain are visible. A baking sun, high temperature, and cloudless skies do not tend to better matters.

A Severe Sentence on a Medical Man.

In the sessions court Mr. S. P. Chatterjee was tried on six charges of giving false evidence and false information in a post-mortem report on April 17th. Two Burmans died from injuries received on the skull in the course of an attack on certain villagers in Nyimaung village. Subsequently when the bodies were exhumed both skulls showed unmistakeable fractures. Nevertheless the accused in his post-mortem reports and in his evidence in the magistrates' and sessions courts declared that there were no bones broken. As a result of his evidence four prisoners were convicted only of causing hurt and sentenced to short terms of imprisonment. The defence was that the accused did not look at the skull. A case in all essentials similar to this was in 1892 laid before the Government Advocate, Mr. Fox, now chief judge, and his opinion was that every man was bound to exercise due care and attention. Nevertheless, according to the sessions judge, the contrary was a widely established belief in Burma and a lax course of procedure based on the belief that a medical man could shut his eyes when he liked prevailed in most parts of the province. Many miscarriages of justice resulted from this belief. These facts were taken into consideration and the accused was sentenced to three years' rigorous imprisonment on all charges. Mr. Chatterjee has preferred an appeal to the chief court against this severe sentence which took no account of evidence given on the prisoner's behalf by a civil surgeon.

Europeans and Vaccination.

The board of directors of the East Indian Railway has drawn attention to the refusal of certain European employees of the line to allow their children to be vaccinated and has added that it cannot allow the health of the general community to be endangered by the refusal of such employees to conform to the regulations on this subject. In any further cases of such refusal the medical officers of the company have instructions to communicate with the head of the department concerned and if the refusal is still persisted in the case will be brought to the notice of the agent for orders as to whether the necessary notice terminating the employee's service with the company shall be given to him.

Plague in Burma.

The official plague report for April for the whole of Burma states that there was a further decrease of plague in the month, the figures showing 461 seizures and 430 deaths, as compared with 1081 seizures and 1014 deaths in March, and 1523 seizures and 1431 deaths in February.

The Health Officer of Bombay.

Dr. J. A. Turner, health officer to the Bombay municipality, has gone on a short leave after nearly eight years of uninterrupted work in this city. Since he was appointed to the office the cost of the plague preventive measures has been reduced by two-thirds. After a baffling fight the plague mortality has been very greatly reduced and the last seasonal epidemic was by far the mildest which the city has experienced. The years of Dr. Turner's administration have been years of substantial progress in local sanitation. The health department is more efficiently managed and the sanitary conditions of the city have materially improved. Thanks to the scientific inquiries which Dr. Turner was the means of setting on foot, we have an accurate knowledge of the etiology of plague and are beginning to understand something of the epidemiology of the disease.

May 22nd.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The Council of the above College on June 18th conferred the diploma of Fellow upon 19 candidates who successfully passed the *Final Examination in Surgery, Surgical Anatomy, and Pathology* held on May 22nd, 25th, 26th, 27th, 28th, and 29th. 68 candidates presented themselves for this examination, of whom 22 were approved (including three who have not yet attained the requisite age of 25 years) and 46 were rejected. The following are the names of the gentlemen upon whom the diploma of Fellow was conferred:—

John Johnson Urwin, Captain I.M.S., M.B., C.M. Glasgow, M.R.C.S., L.R.C.P., Glasgow University and St. Bartholomew's Hospital; Archibald Montague Henry Gray, M.D., B.S. Lond., M.R.C.P., M.R.C.S., University College Hospital; Geoffrey Seccombe Hett, M.B. Lond., M.R.C.S., L.R.C.P., University College Hospital; Clifford Arthur Moore, M.B., B.S. Lond., M.R.C.S., L.R.C.P., University College, Bristol, and London Hospital; Harold Rischbieth, M.A., B.C. Cantab., M.R.C.S., L.R.C.P., Cambridge University and London Hospital; Hamilton Irving, M.B., Ch.B. Vict., M.R.C.S., L.R.C.P., Manchester University and London Hospital; James Glenny Gibb, M.B., B.S. Lond., M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Montague Leonard Hine, M.D., B.S. Lond., M.R.C.S., L.R.C.P., Middlesex Hospital; Charles Max Page, M.B., B.S. Lond., M.R.C.S., L.R.C.P., St. Thomas's Hospital; Robert Davies-Colley, M.A., B.C. Cantab., M.R.C.S., L.R.C.P., Guy's Hospital; Donald Whatley Roy, M.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., Cambridge University and St. George's Hospital; Samuel Wilfred Daw, M.B., B.S. Lond., M.R.C.S., L.R.C.P., Guy's Hospital; Alexander Kinder, M.B., B.Ch., B.Sc. New Zealand, M.R.C.S., L.R.C.P., Otago University and London Hospital; Harold Arthur Robert Edmond Unwin, M.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., Cambridge University and St. Thomas's Hospital; Claude Howard Stanley Frankau, M.R.C.S., L.R.C.P., St. George's Hospital; George Ewart Wilson, M.B. Toronto, M.R.C.S., L.R.C.P., Toronto University and London Hospital; George Charles Edward Simpson, B.A., M.B., B.C. Cantab., B.Sc. Lond., M.R.C.S., L.R.C.P., Cambridge University and St. Bartholomew's Hospital; Wilfred Watkinson Holtzmann, B.C., M.B. Cantab., Cambridge University and London Hospital; and Arthur Rendle Short, M.D., B.S., B.Sc. Lond., University College, Bristol.

Licences in *Dental Surgery* were also conferred by the Council upon the following gentlemen who have now complied with the by-laws of the College:—

Alec Linford Saul, Guy's Hospital; John Battersby, M.B., Ch.B. Manchester, Manchester University; and Percy Samuel Harrison and William Alfred James, Guy's Hospital.

UNIVERSITY OF CAMBRIDGE.—Dr. L. Humphry has been appointed Assessor to the Regius Professor of Physic for the ensuing academical year. The following degrees were conferred on June 18th:—

M.D.—T. R. Elliott and J. M. Hamill, Trinity; and J. Lambert, Downing.
M.B., B.C.—R. G. Chase, Trinity; and M. R. Sawhny, Downing.
M.B.—G. W. Goodhart, Trinity; A. S. M. Palmer, Jesus; and N. M. Fergusson, Magdalen.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held in June the following candidates passed in the subjects indicated:—

Surgery.—F. M. Cunningham (Section I.), Royal Free Hospital; C. P. R. Harvey (Sections I. and II.), London Hospital; J. M. Murray (Section II.), Royal Free Hospital and Durham; H. C. Simpson (Sections I. and II.), Edinburgh; and W. H. Tomlinson, Manchester.
Medicine.—A. Bernstein (Sections I. and II.), Manchester; G. J. Eady (Section II.), St. Bartholomew's Hospital; C. P. R. Harvey (Section II.), London Hospital; O. C. H. L. Moll (Section II.), Guy's Hospital; A. D. Rees (Sections I. and II.), Charing Cross Hospital; H. C. Simpson (Sections I. and II.), Edinburgh; A. P. Van Ryn (Sections I. and II.), Leyden; and G. F. Wilson (Section I.), London Hospital.
Forensic Medicine.—A. Bernstein, Manchester; J. A. Laughton, Charing Cross Hospital; and H. V. White, Manchester.
Midwifery.—A. Bernstein, Manchester; A. P. Van Ryn, Leyden; and H. V. White, Manchester.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: C. P. R. Harvey, O. C. H. L. Moll, J. M. Murray, H. C. Simpson, and W. H. Tomlinson.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* The title of Professor has been granted to Dr. Max Neuhaus, assistant in the surgical clinic of the Charité. Dr. Wolfgang Heubner has been recognised as *privat-docent* of Pharmacology.—*Buenos Ayres:* Professor A. Fischel, of the German University of Prague, has been appointed to the chair of Normal and Descriptive Anatomy.—*Chicago (North-Western University):* Dr. John B. Murphy, of the Rush Medical College, has been appointed to the chair of Surgery in succession to Dr. Weller van Hook who has resigned.—*Naples:* Dr. Aldo Albaique has been recognised as *privat-docent* of Topographical Anatomy.—*Pavia:* Dr. Saverio Verson has been recognised as *privat-docent* of Histology.—*Tübingen:* Dr. Müller, of the Anatomical Institute, has been granted the title of Extraordinary Professor.—*Utrecht:* Dr. Rudolf Magnus of Heidelberg has been appointed to the chair of Pharmacology.—*Vienna:* Dr. Robert Doerr has been recognised as *privat-docent* of General and Experimental Pathology.

ROYAL COLLEGE OF SURGEONS IN IRELAND: BARKER ANATOMICAL PRIZE.—The Barker anatomical prize of £21 is offered for competition in 1909 under the well-known conditions. The prize is open to any student whose name is on the anatomical class list of any school in the United Kingdom and the preparations entered must be placed in charge of the Curator on or before April 30th, 1909. The prize is offered for a dissection from behind of the lumbo-sacral plexus. The preparations must be sent to the Curator of the Museum, Mr. A. H. White, Royal College of Surgeons in Ireland, each being marked with a fictitious signature and accompanied by a sealed envelope bearing outside the same signature and containing within the full name of the competitor and a declaration to the effect that the work of the preparation has been carried out by himself. The printed form necessary for this declaration can be obtained on application to the Curator. The dissections are to be mounted in vessels fitted with glass covers, but the covers must not be sealed down. Earthenware basins and plaster-of-Paris settings are not compulsory if the specimens can be equally well displayed and preserved by other means. The dissections for which prizes are awarded become the property of the College and no prize is awarded unless sufficient merit be shown, 70 per cent. of the total marks being the minimum. The adjudicators are the Curator of the Royal College of Surgeons in Ireland for the time being, the President of the College, and the professor of anatomy of the University of Dublin.

THE ROYAL METEOROLOGICAL SOCIETY.—The annual dinner of this society was held on June 16th at the Trocadéro Restaurant, Dr. H. R. Mill, the President, being in the chair. Among those present were Sir Benjamin Stone, M.P., Mr. E. B. Barnard, M.P. (chairman of the Metropolitan Water Board), Captain Muirhead Collins (Agent-General for the Commonwealth of Australia), Dr. J. J. H. Teall, F.R.S. (Director of the Geological Survey), Dr. C. Theodore Williams, M.V.O., Colonel R. C. Hellard, C.B. (Director of the Ordnance Survey), and Mr. Andrew Watt (secretary of the Scottish Meteorological Society). After the loyal toasts had been duly observed, Dr. Williams proposed "The Visitors," to which Captain Collins and Dr. J. D. McClure responded. Mr. Barnard then proposed the "Royal Meteorological Society." The President, in responding, referred to the work of the society during the past year and to the steps which had been taken in connexion with the scientific investigation of the upper air, and in creating an interest in the study of meteorology among teachers, with a view to its ultimate inclusion in school work. With the object of promoting a closer union between working meteorologists of the Empire, an Imperial Meteorological Conference was to be held at Ottawa next month, to which he was going as the representative of the society. He also stated that in the furtherance of their wide scheme, they received no help from Government, and no recognition in the way of representation on the visiting bodies of such institutions as the Greenwich and Kew Observatories, which were largely devoted to meteorology. They did not complain but were desirous that the public should not measure their aims and the solid work which they were doing by the standard of official recognition. Mr. Baldwin Latham proposed "Kindred Institutions," to which Dr. Teall, Captain Lyons, and Mr. Watt responded.

INSPECTION OF FOODSTUFFS AT BRITISH PORTS.—The publication is announced of draft regulations made by the Local Government Board under the Public Health (Regulations as to Food) Act, 1907. These regulations relate to the duties of medical officers of health and other officers in regard to the inspection and examination of foodstuffs landed in port sanitary districts. A separate series has also been issued respecting the examination at the ports of certain imported meat foods.

THE DINNER TO MEMBERS OF THE "VOYAGES D'ÉTUDES MÉDICALES."—We are informed by the organisers that it has been decided to hold this dinner on Thursday, July 16th, at the Hotel Cecil, Strand, W.C., and not at the Franco-British Exhibition, as previously announced. As the number of places is limited it is essential that those who wish to be present should send their names to Dr. Leonard P. Mark (49, Oxford-terrace, Edgware-road, W.), or Mr. P. Macleod Yearsley (31, Harley-street, W.), and their subscriptions (not less than *two guineas*) to the treasurer, Dr. J. Dundas Grant, 18, Cavendish-square, W., at the earliest possible date. Those wishing for a dinner ticket for a lady as well should mention the fact, as the number of these tickets will be limited.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. A. K. Biêloussoff, professor of anatomy and physiology in the University of Kharkoff.—Dr. L. E. Blanche, formerly professor of medical natural history in the Medical School of Rouen.—Dr. Zimmermann of Köln, the Nestor of German medical men, aged 98 years.—Dr. Richard Peters, *privat-docent* of children's diseases in the St. Petersburg Military Medical Academy.—Dr. John W. Cuddy, formerly professor of medicine and of dermatology in Baltimore.—Dr. N. P. Tolochinoff, formerly professor of midwifery and gynæcology in the University of Kharkoff.

THE SUSSEX AND HAMPSHIRE MEDICAL BENEVOLENT SOCIETY.—The Sussex Medical Benevolent Society has extended its operations so as to include Hampshire and will be known for the future as "The Sussex and Hampshire Medical Benevolent Society." All registered practitioners in the counties of Sussex and Hampshire are eligible for election as members of the society. The objects of the society are to aid the widows and children of members dying in indigent circumstances; to aid the sisters of deceased members, being single women or widows, who have lived with their brothers as their housekeepers for a period of not less than five years; to aid such members as are wholly or partially incapacitated by age or permanent bodily infirmities, or who are disabled by severe illness or injury from practising for a period of six months; to aid in the education of the children of members thus incapacitated or temporarily disabled; and generally to assist any deserving case of necessity. Dr. L. A. Parry, 83, Church-road, Hove, is the honorary secretary for Sussex, and Dr. A. M. Barford, 30, Grove-road, Southsea, the honorary secretary for Hampshire.

THE MIDLAND COUNTIES ASYLUM.—At the annual meeting of the friends and supporters of the Midland Counties Asylum for Feeble-minded Children the treasurer, Mr. Joseph Taunton, congratulated the subscribers on the fact that during the last five years the accommodation at the asylum had been nearly doubled and the facilities for training the children had been greatly increased and he pointed out that the asylum was quite full and further applications for admission could only be considered as vacancies occurred. There is a demand for additional accommodation and it would be well if the work of the institution could be extended. At present, however, that is not possible because the last year's expenditure exceeded the ordinary income by £26 and there is an overdraft at the bank for £93 in association with the extension fund. Therefore, until more means are obtainable both for upkeep and extension the work of the institution cannot be increased. Both the Marquis of Hertford, who moved the adoption of the report, and Mr. F. E. Muntz, who seconded, expressed their disappointment that the institution had, as yet, received no contributions from the Birmingham Hospital Saturday Fund. The Marquis of Hertford stated that 25 per cent. of the inmates of the asylum belonged to Birmingham, and he expressed the opinion that the managing committee of the asylum was entitled to some help from the city, and Mr. Muntz remarked that as Birmingham was quite ready to send appeals for Birmingham objects to people outside the city the asylum committee was justified in asking that Birmingham should respond to appeals made by an outside institution.

A CONVERSAZIONE of the Royal Society of Arts will be held in the Natural History Museum, South Kensington, on Thursday evening next, July 2nd, at 9 P.M.

MEDICAL MAGISTRATE.—Mr. J. H. Dudgeon, L.R.C.P., L.R.C.S. Edin., has been appointed a justice of the peace for the county of Cumberland.

THE certificates and prizes in connexion with King's College, London, will be presented by the Right Rev. the Bishop of Central Pennsylvania on Wednesday, July 1st, at 3 P.M.

BROMPTON HOSPITAL SANATORIUM, FRIMLEY.—On Saturday next, July 4th, the Brompton Hospital Sanatorium at Frimley will be open for inspection, when the patients can be seen at the graduated work recently described in THE LANCET. Any medical man wishing to visit the sanatorium on that date should communicate with the medical superintendent who will forward a formal invitation.

OPHTHALMOLOGY AND THE UNIVERSITY OF OXFORD.—An announcement in our last issue of the Ophthalmological Congress to be held at Oxford in July contained an outline of the work arranged for the post-graduate course which is to precede the congress. We desire to make it clear that this post-graduate course of instruction in ophthalmology will begin on July 6th and will be brought to a conclusion by the congress of ophthalmic surgeons upon July 16th and 17th.

THE LEAGUE OF MERCY.—At the invitation of the Prince and Princess of Wales a reception was held on June 24th in the garden of Marlborough House. Previously to their Royal Highnesses receiving their guests on the lawn about 140 presidents and lady presidents of the League assembled in the Saloon of Marlborough House, when a report of the work of the League during the past year was read by Mr. J. Harrison, M.V.O., one of the honorary secretaries. In his reply the Prince of Wales said the report for the year was very satisfactory.

DONATIONS AND BEQUESTS.—Mr. Timothy White, of Sall Park, Norfolk, who left estate valued at £202,946 gross, with net personalty £67,324, has bequeathed £500 to the Portsmouth and Gosport Hospital, £500 to the Norwich Hospital, £100 to Guy's Hospital, London, and £100 to the London Hospital. After certain other legacies are paid the residue of his real and personal estate he left upon trust for one of his sons and his heirs in tail male, whom failing to his other sons and their heirs in tail male successively, whom failing to Guy's Hospital and the London Hospital in equal shares.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Tuberculosis Prevention (Ireland) Bill.

AFTER some delay the text of the Tuberculosis Prevention (Ireland) Bill, which has been introduced into the House of Commons by Mr. BIRRELL, the *Chief Secretary to the Lord Lieutenant for Ireland*, has been issued. The Bill is designed "to prevent the spread and provide for the treatment of tuberculosis and for other purposes connected therewith." Two most important provisions are contained in the measure. It provides for the notification of persons suffering from tuberculosis and it permits county councils to establish hospitals and dispensaries for the treatment of persons in their areas who have contracted the disease. The proposals are of so far reaching a character that it will be well to quote *in extenso* some of the salient portions of the Bill.

The first clause relates to notification. It runs thus: "1. If any medical practitioner attending on any person becomes aware that that person is suffering from tuberculosis of any form, or at any stage, and in any circumstances prescribed by an Order of the Local Government Board under this section, the medical practitioner shall forthwith send to the medical officer of health of the district in which the patient is a certificate in the prescribed form and containing the prescribed particulars. 2. The Local Government Board may from time to time by Order prescribe the *forms* and stages of tuberculosis to which, and the circumstances in which, this section shall apply. 3. Any certificate required to be sent to a medical officer of health under this section may be sent either by delivering it to that officer or by leaving it at his office or residence or by sending it by post addressed to him at his office or at his residence. 4. If any medical practitioner required by this section to send a certificate fails to send the certificate forthwith he shall be liable *on summary conviction* to a penalty not exceeding *forty shillings*. 5. The sanitary authority shall pay to every medical practitioner for each certificate duly sent by him in relation to a patient in their district a fee of 1*s.* if the case occurs in an infirmary, public hospital, or workhouse, and a *fee of 2s. 6d. if* the case occurs elsewhere. Where the medical practitioner required by this section to send a certificate is himself the medical officer of health of the district he shall be entitled to the fee to which he would be entitled if he were not such medical officer. 6. A payment made to any *medical practitioner* in pursuance of this section shall not disqualify the practitioner from serving as a member of any county or district council or as a guardian of any union. 7. The Local Government Board may make regulations for carrying into effect the provisions of this section and such regulations shall, among *other matters, prescribe* the form of certificate to be sent under this section and the particulars to be inserted therein, and shall provide for the proper custody of all certificates, and for securing that, so far as is in the opinion of the Board consistent with the public advantage, no publicity shall be given to any of the particulars contained in any such certificate. The sanitary authority shall gratuitously supply *forms of certificate* to any medical practitioner residing or practising in their district who applies for the same. 8. In this Section the expression 'medical officer of health of the district' means:—(*a*) *as respects any district for* which there is a medical officer of health, that officer; and (*b*) elsewhere, the medical officer of health of the dispensary district."

Clause 2 of the Bill provides for the disinfection and cleansing of premises, bedding, clothing, or articles exposed to or likely to retain infection, in like manner as if tuberculosis were an infectious disease to which the Public Health (Ireland) Act, 1878, and the Infectious Diseases (Prevention) Act, 1890, applied.

There are several important subsections in Clause 3 which relates to *the provision of hospitals and dispensaries by county councils.* The first subsection is as follows: "A county council may if they think fit provide hospitals and dis ensaries for the treatment of inhabitants of their county suffering from tuberculosis, and for that purpose may (*a*) themselves establish and maintain such hospitals and dispensaries; or (*b*) enter into an agreement with any person having the management of any hospital or dispensary for the reception, maintenance, and treatment therein of any such inhabitants of their county as aforesaid." In another subsection power is given to *two or more county councils to combine in providing* a common hospital or dispensary for the treatment of tuberculosis. The fifth subsection is in the following terms: "A county council shall, for every hospital or dispensary established by them, appoint (*a*) a medical superintendent having the prescribed qualifications at such salary as may be approved by the Local Government Board; and (*b*) such nurses having the prescribed qualifications and other officers and attendants as are necessary for the requirements *of* the hospital or dispensary at such respective salaries as the county council think *proper*, and may dismiss any person so appointed as they think fit, excepting the medical superintendent, who shall not be dismissed without the concurrence of the Local Government Board."

Clauses 4 to 12 elaborate the administrative machinery by which effect is to be given to the provisions of Clause 3.

Powers are sought by *Clause 13 for sanitary authorities* to defray the expenses of lectures and the distribution *of* literature relating to tuberculosis.

The next clause enables a county council to appoint a bacteriologist, with such qualifications and at such remuneration as may be approved by the Local Government Board, *for* the examination of meat or milk or milk products, and of sputum or pathological specimens and, at their discretion, to dismiss such bacteriologist. Subject to regulations to be made by the county council, the services of the bacteriologist shall, *without charge, be at the disposal of* any sanitary authority within the county for which he is appointed.

Other clauses in the Bill have reference *to* such matters as the taking of samples of milk and milk products and the destruction of cows affected with tuberculosis of the udder.

Experiments on Living Animals.

A return to the Home Secretary shows that *73,374 experiments* on living animals were performed under licences and certificates in 1907. The number is 27,301 more than in 1906. The experiments tabulated as inoculations, hypodermic *injections*, and some few other proceedings performed without anæsthetics, numbered 70,794 last year. The increase of 27,507 under this head is mainly due to the experiments performed in the course of cancer *investigation*. The total number of experiments performed for this purpose at three *institutions* during 1907 was 45,032, of which 44,789 were *classified as inoculations*, hypodermic injections, and other proceedings *performed* without anæsthetics. Professor THANE, the inspector, reports that during the yea a large number of experiments almost wholly simple inoculations and similar proceedings were performed either on behalf of official bodies, with a view to the preservation of the public health, or directly for the diagnosis and treatment of disease. Several county councils and municipal corporations have their own laboratories in which bacteriological investigations are carried on, including the necessary tests on living animals; and many others have arrangements by which similar observations are made on their behalf in the laboratories of universities, colleges, and other institutions. A sewage farm is registered as a place in which experiments on living animals may be performed in order that the character of the effluent may be tested by its effects on the health of fish. The Board of Agriculture has two laboratories which are registered for the performance of experiments having for their object the detection and study of the diseases of animals. Mr. THANE further reports that in other places experiments have been made on behalf of the Home Office, the War Office, the Local Government Board, the Board of Agriculture and Fisheries, the Metropolitan Asylums Board, the Royal Commission on Sewage Disposal, the Royal Commission on Tuberculosis, and the Sleeping Sickness Committee of the Royal Society. 51 licensees return over 8300 experiments which were performed for Government departments, county councils, municipal corporations, or other public health authorities; 2825 experiments were performed by two licensees for the Royal Commission on Tuberculosis; and 12 licensees performed nearly 4500 experiments for the preparation and testing of antitoxic sera and vaccines and for the testing and standardising of drugs.

Sir W. THORNLEY STOKER, the inspector for Ireland, reports that the experiments performed on living animals in that country were 158 in number, four being under licence alone and 154 under certificates. The animals experimented on were mice, guinea-pigs, rabbits, dogs, goats, and a cat. The experiments were physiological, pathological, and in two instances therapeutical. 11 were for the purpose of demonstrations of the phenomena of circulation, respiration, cardiac control, and secretion. The rest were inoculations for diagnosis, the study of tubercle, typhoid fever, cholera, streptococcal infections, effects of x rays, identification of blood stains, the treatment of goitre, and injection of a trypanosome found in the blood of bats to study the possibility of infection. Studies were made of gastric movements, of the functions of the pancreas, and of kidney secretion.

Prevention of Tuberculosis in Scotland.

The Secretary for Scotland will be asked at an early date whether he will consent to introduce for Scotland a measure on the lines of the Tuberculosis Prevention (Ireland) Bill.

Nurses Registration Bill.

On Tuesday Lord AMPTHILL introduced a Nurses Registration Bill into the House of Lords. He said that it was to provide for the registration of trained nurses and to secure a definition of their qualifications.

Indecent Advertisements.

Further evidence in relation to indecent advertisements has been tendered to the Joint Committee of both Houses of Parliament. On Monday the Rev. R. USHER, vicar of Netherbury, appeared as a witness and handed to the committee a selection of periodicals and other literature containing advertisements recommending the prevention of conception. He spoke of the dissemination of this class of advertisement in the rural districts and recommended that the circulation of such printed matter and the sale of the goods in question should be made a punishable offence.

HOUSE OF COMMONS.

THURSDAY, JUNE 18TH.

The Belfast Health Commission.

Mr. DEVLIN asked the Chief Secretary to the Lord Lieutenant of Ireland whether he could state the probable cost of the Belfast Health Commission; whether he was aware that the health committee of the Belfast corporation refused to recommend the corporation to take the responsibility for the publication of the report of the Commission; and whether the Local Government Board would take any steps to see that the recommendations of the Commissioners were carried out.—Mr. BIRRELL replied: The Local Government Board is not yet in a position to estimate the cost of the Belfast Health Commission as the expenses of printing remain to be ascertained. The public health committee of Belfast corporation refused to recommend the corporation to take the responsibility of printing additional copies of the report for public circulation, but the report has since been laid upon the table of the House and copies will thus become available. As regards the honourable Member's concluding inquiry I can only refer him to my previous answer—namely, that having regard to the many important recommendations made by the Commission the corporation must be allowed a reasonable time for decision before the Local Government Board can take action.

The Ruchill Fever Hospital, Glasgow.

Mr. WATT asked the Secretary for Scotland with reference to the Local Government Board inquiry into the overcrowding and understaffing of Ruchill Fever Hospital, Glasgow, how the local authority had dealt with the officials found by the Commissioners of the Local Government Board to be responsible, viz., the medical superintendent, the medical officer of health, and the matron.—Mr. SINCLAIR replied: After full and careful consideration the conclusions come to by the local authority were as follows. The medical superintendent was put on six months' probation. The explanation made to the local authority by the medical officer of health was considered satisfactory. The matron, having expressed regret for the conduct to which exception had been taken, was allowed to retain her position.

Milk and Tuberculosis.

Mr. GUINNESS asked the President of the Local Government Board whether, in view of the recent circular of the United States Department of Agriculture showing the danger of infection from butter made from tuberculous milk, he would, in his promised Milk Bill, make provision to prevent the sale of such butter.—Mr. MASTERMAN (who answered) said: My right honourable friend has seen the circular referred to. He will consider the point raised by the honourable Member, but the Bill which he proposes to introduce will endeavour to prevent the supply of milk from tuberculous cows and thus to prevent also the sale of butter made from such milk.

The Inspection of Meat and Milk at Lisburn.

Mr. DEVLIN asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to the report of the Local Government Board inspector with regard to the insanitary condition of the dairies, cowsheds, and milkshops in the Lisburn urban district, the objectionable position and unsatisfactory condition of the slaughter-yards, the want of a public abattoir, and the lack of any provision for the inspection of the meat and milk supply of the district; and whether the Local Government Board proposed to take any steps to urge or to compel the local authority to take action in the matter.—Mr. BIRRELL replied (by written answer): The report of the Local Government Board's inspector contains references to the matters mentioned in the question. The Board has urged the council to appoint an expert inspector such as a veterinary surgeon to supervise the meat and milk supplies of the urban district.

Medical Officers of Health in the Highlands.

Mr. WEIR asked the Secretary for Scotland to state how many medical officers of health had been appointed in the Highland crofting counties during the last five years, and how many of them possessed a diploma in sanitary science, public health, or State medicine, as required under Section 54 of the Local Government (Scotland) Act, 1889.—Mr. SINCLAIR furnished the following written reply: In the Highland crofting counties there have been appointed during the last five years medical officers of health for three counties, six districts of counties, and four parishes or portions of districts. All possess the statutory diploma except four, and two of these have been appointed on condition that they obtain it.

The Medical Officer of Health of Hertfordshire.

Mr. G. J. COOPER asked the President of the Local Government Board whether the county council of Hertfordshire, in reappointing its medical officer of health, added to his duties the appointment of inspecting the children in the elementary schools in the county; whether he could state the number of children to be inspected; whether the medical officer was required to reside in the county and to devote the whole of his time to the duties of his office; whether this medical officer's office had been fixed at Guy's Hospital, London; whether any grants and travelling expenses had been made to maintain this office; whether this position was convenient to the parents of the children and people of Hertfordshire; whether any sanction of his department had had to be obtained; and, if so, whether he would state the reasons why he had sanctioned the selection of an office a considerable distance from the county.—Mr. BURNS replied (by written answer): I understand that the county council has appointed its county medical officer to act as chief school medical officer under the Education Acts and that he is required to devote the whole of his time to the duties of these two offices. A sum of £200 per annum appears to be allowed for the provision of a clerk and suitable furnished offices. He is also allowed the necessary travelling expenses and disbursements for stationery and £20 for the provision of a typewriter. Hitherto the office of the medical officer seems to have been at Guy's Hospital, but I do not know whether the arrangement has been continued. No sanction on my part is required to the appointment which has been made or to the selection of an office, and I have no information on the points mentioned in the question other than those with which I have dealt above. I may say, however, that when appointing a chief school medical officer the county council also appointed a number of district medical officers of health and other medical practitioners to act as school medical officers for the sanitary districts in its area.

THE ROYAL COLLEGE OF SURGEONS IN IRELAND AND THE UNIVERSITIES BILL.

Repeated allusion to the position of the Royal College of Surgeons in Ireland was made on Friday, June 19th, in the debate in the Standing Committee of the House of Commons which is charged with the consideration of the Irish Universities Bill. The subject arose on Mr. Butcher's amendment to Clause 2, which deals with the constituent colleges of the new universities and the powers to affiliate other institutions.

Mr. BUTCHER moved as an amendment to include the following subsection in the clause: "On the passing of this Act, before the powers of the Commissioners determine, the Royal College of Surgeons in Ireland, the Royal College of Science in Dublin, Maynooth College, and Magee College may be affiliated to one or other of the two new universities subject to the provisions of the charter and to the statutes and regulations of the university, and any subsequent affiliation shall be made by statute of the university." He explained that his object was to facilitate the early affiliation of these institutions, if it was so desired. With regard to the Royal College of Surgeons in Ireland, he remarked that its position was so well known that he thought nobody would object to its fitness for affiliation with the new university in Dublin if it so desired.

Captain CRAIG took objection to the inclusion of Maynooth College and Magee College in the amendment, but he was strongly in favour of the inclusion in it of the Royal College of Surgeons in Ireland and the Royal College of Science in Dublin. He thought that it was time that they should have a definite statement with regard to the Royal College of Surgeons, as all Ireland was waiting to know how the Bill was going to affect it. The feeling had gone abroad that the Government was intending to crush out the Royal College of Surgeons, and it would only be reassuring to have a statement from the Chief Secretary to the Lord-Lieutenant that that body should be allowed the full privileges of being affiliated and kept up to a high standard.

Mr. BIRRELL (Chief Secretary to the Lord Lieutenant of Ireland) replied that the committee would be wise to leave the question of affiliating the various bodies mentioned in the amendment to the decision of the senates of the new universities. In his opinion the committee was not competent to decide on the affiliation of these bodies. They had not the information before them to enable them to carry out such an operation satisfactorily. They were bound by their former decisions to leave the whole responsibility to the senates, with the exception that the only places which could be affiliated should be seats of the higher learning. The honourable and gallant Member (Captain Craig), while opposed to Maynooth College and Magee College, was greatly attached to the claims of the Royal College of Surgeons in Ireland and also to the Royal College of Science for affiliation. These matters were not for the committee and were not for the Chief Secretary. They should be left to the senates. He would not express any opinion. The opinion that he was fighting against the Royal College of Surgeons in Ireland was entirely unfounded. He knew the value of its work and he had not the faintest animus against the Royal College. The question of affiliation was not one for the Commissioners but for the senates themselves.

An amendment to exclude Maynooth College and Magee College from Mr. Butcher's proposal was rejected by 31 votes to 2.

Mr. BUTCHER's amendment was negatived without a division.

On the question that Clause 2 should stand part of the Bill,

Captain CRAIG in moving its rejection again took occasion to refer amongst other matters to the position of the Royal College of Surgeons in Ireland. The Chief Secretary had said that he would leave the question of affiliation to the senates of the new universities, but he (Captain Craig) distrusted the senates. The Bill included the Cecilia-street School of Medicine in Dublin but it held out no hope for the Royal College of Surgeons in Ireland.

Mr. BIRRELL pointed out that what the Bill concerned was the medical faculty of the new university in Dublin.

Captain CRAIG (continuing) said that for all practical purposes the Cecilia-street School was a part of the Bill of the right honourable gentleman and the Royal College of Surgeons was not. They all knew that perfectly well. That was a serious point, so serious indeed that those who had been interested in the Royal College of Surgeons for the magnificent work which it had done in the past and was doing now would at least try to see that it was not to be superseded by any other medical school.

Mr. LONG, in the course of his speech, also pointed out that the Royal College of Surgeons in Ireland and the Royal College of Science would be injured unless the senate of the new university gave them recognition. He had done his best to acquaint himself with the facts, and if the new university, including the Cecilia-street School, were able to provide by means of public funds a medical education of a valuable character at a much lower rate of fees than the Royal College of Surgeons could do it was as clear as the sun was in the heavens that the Royal College of Surgeons must suffer.

Mr. BIRRELL said that he would like to say a word about the position of the Royal College of Surgeons in Ireland. He was not at all sure that at this moment it would accept affiliation to the new university. At the present moment the thoughts of the Royal College were turned towards obtaining money. His belief was that if it got money from the Treasury it would prefer to remain outside the university. It might desire affiliation if it did not get money enough. The committee could not affiliate bodies against their will.

The clause was carried by 25 votes to five.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BETHUNE, WILLIAM, M.B., C.M. Edin., has been appointed Medical Officer of Health for Bideford (Devon) Rural District.

BETTS, LEONARD BOWRING, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Parkham District by the Bideford (Devon) Board of Guardians.

BUTTERWORTH, J. J., M.D., B.Ch. Vict., D.P.H., has been appointed School Medical Superintendent to the Education Committee of the Lancashire County Council.

CLARK, CHARLES A., L.D.S., has been appointed Honorary Radiographer to the Royal Dental Hospital.

CLARKE, H. H. R., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Stourbridge District of the county of Worcester.

CLIFFORD, HAROLD, M.B. Lond., F.R.C.S. Edin., has been appointed Honorary Assistant Surgeon for Women at the Manchester Northern Hospital for Women and Children.

DAVIS, HALDIN, M.B., B.Ch. Oxon., has been appointed Honorary Anæsthetist to the Western General Dispensary, Marylebone-road, N.W.

MORLEY, ARTHUR S., F.R.C.S. Eng., has been appointed Honorary Anæsthetist to the Western General Dispensary, Marylebone-road, N.W.

STEADMAN, FRANK ST. J., L.R.C.P. Lond., M.R.C.S., L.D.S. Eng., has been appointed Joint House Anæsthetist to the Royal Dental Hospital.

WILLEY, FLORENCE E., M.D., M.S., B.Sc. Lond., has been appointed Assistant Physician for Diseases of Women at the Royal Free Hospital.

WILLIAMSON, A. M., M.B., C.M. Glasg., has been appointed Medical Officer of Health to the Edinburgh Town Council.

WILLIS, W. M., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Nottingham (East) District of the county of Nottingham.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

AYLESBURY, ROYAL BUCKINGHAMSHIRE HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, washing, and lodging.

BANBURY, HORTON INFIRMARY.—House Surgeon. Salary £80 per annum, with board and residence.

BATH, ROYAL MINERAL WATER HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with lodging, board, and laundry.

BEXLEY, KENT, LONDON COUNTY ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £160 per annum, with board, apartments, and washing.

BIRMINGHAM CITY HOSPITAL, Lodge-road.—Assistant Medical Officer. Salary £120 per annum, with board, residence, &c.

BIRMINGHAM MATERNITY HOSPITAL.—House Surgeon for six months. Salary at rate of £50 per annum, with board, residence, and laundry.

BRIDGWATER HOSPITAL.—House Surgeon, for six months. Salary at rate of £80 per annum, with board, lodging, and washing.

BURNTWOOD, NEAR LICHFIELD, COUNTY ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, increasing to £200, with board, lodging, attendance, and washing.

CAMBRIDGE, ADDENBROOKE'S HOSPITAL.—Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, residence, and laundry.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.—Assistant Anæsthetist (Honorary).

CHESTER, CITY OF.—Assistant Medical Officer of Health. Salary £250 per annum.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physician for six months. Salary at rate of £50 per annum, with board, residence, and washing.

COLCHESTER, ESSEX COUNTY HOSPITAL.—House Physician. Salary £80 per annum, with board, residence, and washing.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Junior House Surgeon for six months. Salary at rate of £80 per annum, with rooms, board washing, and attendance.

COVENTRY, CORPORATION OF, EDUCATION COMMITTEE.—Assistant Medical Officer. Salary £250 per annum.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY.—Assistant House Surgeon. Salary £55 per annum, with board and lodging.

EDINBURGH, UNIVERSITY OF.—Lectureship in Diseases of Tropical Climates. Salary £300 per annum.

ENNISKILLEN, FERMANAGH COUNTY HOSPITAL.—House Surgeon. Salary £72 per annum, with board, apartments, and washing.

HERTFORD GENERAL INFIRMARY.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident House Physicians for six months. Salary £25.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Surgeon to Out-patients. Also Anæsthetist.

KING EDWARD VII. SANATORIUM, Midhurst, Sussex.—Junior Assistant Medical Officer, unmarried. Salary £100 per annum, with board, lodging, and attendance.

LANARK, COUNTY OF, LIGHTBURN JOINT HOSPITAL FOR INFECTIOUS DISEASES, Shettleston, near Glasgow.—Resident Physician. Salary £140 per annum, with board, &c.

LEEDS PUBLIC DISPENSARY.—Two Resident Medical Officers. Salary £100 per annum, with board and lodging.

LEICESTER INFIRMARY.—Second House Surgeon. Salary at rate of £100 per annum, with board, apartments, and washing.

LEICESTERSHIRE AND RUTLAND LUNATIC ASYLUM.—Junior Assistant Medical Officer. Salary £150, rising to £180 per annum, with board, lodging, and washing.

LIVERPOOL STANLEY HOSPITAL.—Junior House Surgeon. Salary £60 per annum, with board, residence, and washing.

LONDON THROAT HOSPITAL, 204, Great Portland-street, W.—House Surgeon, non-resident, for six months. Salary at rate of £50 per annum. Also Anæsthetist.

MANCHESTER, MONSALL FEVER HOSPITAL.—Fourth Medical Assistant. Salary £100 per annum, with board, lodgings, and washing.

MANCHESTER, UNIVERSITY OF.—Senior Demonstrator in Physiology. Salary £150, rising to £250 per annum.

MEDICAL MISSION HOSPITAL SETTLEMENT OF WOMEN WORKERS, Canning Town.—Senior Resident Medical Officer (female). Salary £100 per annum.

MILE END OLD TOWN INFIRMARY AND WORKHOUSE, Bancroft-road, E.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing.

MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich-road, S.E.—Junior House Surgeon for six months. Salary at rate of £80 per annum.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood, Middlesex.—Junior Resident Medical Officer. Salary £50 per annum, with board, lodging, &c.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, *Soho-square, London, W.*—Radiographer.

NEW SOUTH WALES, AUSTRALIA, QUEEN VICTORIA HOMES FOR CONSUMPTIVES.—Resident Medical Officers at the King's Table Land Sanatorium and the Thirlmere Sanatorium. Salary £250 per annum, with board and residence.

NORTHAMPTON COUNTY ASYLUM, Berry Wood.—Locum Tenens for 14 weeks. Salary 4 guineas weekly.

NOTTINGHAM CHILDREN'S HOSPITAL.—House Surgeon (female) for six months. Salary at rate of £80 per annum, with board, residence, and washing.

ORKNEY, PAPA WESTRAY PARISH COUNCIL.—Lady Medical Officer and Public Vaccinator. Salary, £85 per annum, with fees, house, and garden.

OXFORD, RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—Junior House Surgeon, unmarried. Salary at rate of £40 per annum, with board, &c.

PORTSMOUTH BOROUGH ASYLUM.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and washing.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone road, N.W.—Resident Medical Officer for four months. Salary at rate of £50 per annum, with board, residence, and washing.

RANGOON MUNICIPALITY.—Health Officer. Salary Rs.1000, rising to Rs.1500 per mensem.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Senior Obstetric Physician. Salary £50 per annum, with board, lodging, and washing. Also Clinical Assistant in Gynæcological Department. Both females.

ST. MARK'S HOSPITAL FOR FISTULA AND OTHER DISEASES OF THE RECTUM, City-road, London, E C.—Honorary Assistant Surgeon.

ST. MARY'S HOSPITAL, London, W.—Resident Casualty House Surgeon for six months. Salary at rate of £100 per annum, with board and residence. Also Resident Assistant Anæsthetist for six months, renewable. Salary at rate of £100 per annum, with board and residence.

ST. PANCRAS AND NORTHERN DISPENSARY, 126, Euston-road.—Resident Medical Officer. Salary £105, with residence and attendance.

SHREWSBURY, SALOP INFIRMARY.—House Physician. Salary at rate of £60 per annum, with board and apartments.

STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—Assistant House Surgeon. Salary £32 per annum, with board, residence, and laundry.

TEIGNMOUTH HOSPITAL, S Devon.—House Surgeon. Salary £70 per annum, with board, lodging, and washing.

WESLEYAN METHODIST MISSIONARY SOCIETY.—Medical Secretary.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon. Salary £80 per annum, with board, lodging, and laundry.

YORK, CITY OF, EDUCATION COMMITTEE.—Assistant Medical School Inspector. Salary £200 per annum.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Ledbury, in the county of Hereford; and at Melton Mowbray, in the county of Leicester.

Births, Marriages, and Deaths.

BIRTHS.

FURBER.—On June 22nd, at Beechcroft, Oxted, the wife of Edward P. Furber, L.R.C.P. Lond., M.R.C.S. Eng., of a son.

MARRIAGES.

THURSTON—MITCHELL.—At St. Paul's Cathedral, Calcutta, on June 1st, 1908, E. Owen Thurston, M.B., B.S. Lond., F.R.C.S. Eng., Captain I.M.S., to Robertina Patterson, daughter of J. C. Mitchell, Esq., late E.I. Ry., and Mrs. Mitchell, Catford, London.

DEATHS.

ABRAHAMS.—On the 21st inst., at his residence, 14, Welbeck-street, Cavendish-square, W., Bertram Abrahams, M.B., B.Sc Lond., F.R.C.P., aged 33, only son of Louis B. Abrahams, of The Cabin, Seaforth-road, Westcliff-on-Sea.

ELLERTON.—On June 17th, at Leamington, Frederic Charles Grant Ellerton, M.R.C.S., L.R.C.P. Edin., in his 89th year.

HIRST.—On the 20th inst., at 248, Victoria Park-road, London, N.E., aged 67 years, Albert Hirst, M.D., F.R.C.P. Edin. Formerly of Prestwich, Manchester.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"THE CURE OF CANCER."

OUR attention is called to a letter in a recent issue of the *Hull Mail*, under the heading "The Cure of Cancer," and over the signature "J. P. Sandlands." We have heard before from this gentleman and remember that having the care of souls he seeks to meddle in a peculiarly mischievous manner with the welfare of bodies afflicted with a terrible disease, of which his own lucubrations prove his amazing ignorance. It passes comprehension that a presumably educated person should set his name to stuff of this sort:—

> "What, then, is conclusive about cancer? (1) It is not a primary, but a secondary disease. (2) Persons do not die of cancer, unless it obstructs some function. (3) Persons often die of liver when the cancer has been cured. John Hodgson, for instance, spat his cancer out of his throat, but he died subsequently of liver. Widow Neal, of Burton Latimer, died of liver some five years after having her cancer cured. (4) The cause of the primary disease is unwholesome food. And so we are on safe ground and can proceed to a rational conclusion. Cancer is curable on the dietetic principle only. On this principle I have cured it. I say this 'after the manner of men.' More correctly speaking we have to say 'Nature does the cure, we can only stop the cause.' Puny man thinks he can do a lot, and really he can only do mischief. I have spent just about £1000 in trying to teach people these things."

It is hard to understand the credulity which this letter shows, unless, indeed, it is a symptom of that uncanny disease "liver," which appears to be endemic in its author's neighbourhood.

THE USE AND ABUSE OF DISTRICT NURSES.

To the Editor of THE LANCET.

SIR,—A few years ago much was said and written on the employment of unqualified assistants, resulting in the action of the Medical Council. I think there is a much greater abuse at the present time. I refer to the district nurse who is "called in" and attends midwifery and sometimes acts as assistant to the club doctor. She is worked night and day for the small remuneration of £60 per annum. The fund is collected by district visitors who induce persons, often in good circumstances, to subscribe 2s. or 3s. a year "and so to be in a position to send for the nurse whenever they wish and so save the doctor's bill." Does not this call for the consideration and action of the Medical Council?

I am, Sir, yours faithfully,
SENEX.

June 15th, 1908.

QUACKERY IN THE NORTH OF ENGLAND.

A CORRESPONDENT has forwarded to us the following cutting from a Northumberland paper:—

> "At the annual conference in connection with the Northumberland and Durham Miners' Permanent Relief Fund it was decided that in future certificates of bone-setters, in whom northern workmen have considerable faith, shall, in applications for relief, be equal in value to those of medical men."

Education does not seem to have spread yet among the Northumberland and Durham miners.

KHORASAN CONSULAR HOSPITAL.

THE annual report of the Khorasan Consular Hospital for 1906 just issued by His Majesty's Consul-General, Major P. Molesworth Sykes, shows that it is growing in popular esteem. In July, 1906, a severe epidemic of small-pox broke out in the city and raged for about three months, during which time more than 7000 deaths occurred. The disease was in a large number of cases of the malignant type. A large quantity of calf lymph was obtained and efforts were made to induce people to attend for vaccination; a considerable number were dealt with, but it was impossible to cope adequately with the enormous numbers needing vaccination. The infants and young children of the city were decimated. In 1906 the Government of India sanctioned a proposal to add a touring hospital assistant, a female hospital assistant, and a second compounder to the medical staff. Towards the end of the year under review the increase in the number of the patients attending was so great that it was decided to separate the medical from the surgical out-patients' consulting room. At the date of writing there had been a marked increase in the daily attendance and also in the numbers of in-patients and of those undergoing major operations. Any increase in the amount of operative work undertaken has a prejudicial effect on the attendance of out-patients, the reason being that the hospital staff is so limited, consisting as it does of only two Indian hospital assistants and one compounder in addition to the agency surgeon, that whenever a major operation is to be done the whole staff has to leave the routine out-patient work and to attend the theatre, one to give the anæsthetic and the other two to assist at the operation. The out-patients who still remain to be attended to in many cases decline to be kept waiting and go away. It is possible that some relief may shortly be found in the more frequent use of local and lumbar anæsthesia for major operations. These forms of anæsthesia have already been introduced with encouraging results, and it is hoped that with increasing experience their use may be greatly extended in the near future. It is evident, however, that the limited staff of the hospital is too fully occupied with the heavy routine work to be able to avail itself of excellent opportunities for research afforded by the large area and diverse nationalities which it serves. It will be remembered that Khorasan occupies the whole of north-east and eastern Persia.

INDECENT ADVERTISEMENTS.

An Indian correspondent forwards us two pages torn from a newspaper called the *Echo of India*, which constitute the most offensive congeries of indecent advertisements that we remember to have seen. One page is chiefly devoted to the two "specifics" "Vim" and "Impodyne," the claims of which are sufficiently indicated by their names, whilst "Genuine French Soluble Pessaries" occupy a conspicuous paragraph. The usual testimonials are printed which are sufficiently objectionable, but hardly more so than are those on the other side of the print which puff the wares of J. W. Wilson and Co., British Manufacturing and Dispensing Chemists, Madras. These nostrums are labeled Syphildyne and Gonorrdyne, as the reader is informed in large type. "Gonorrdyne Injection" and "'Gon' No. 2 Capsules for Gleet" are recommended no less prominently, whilst a place is found for a popular symptomatology of syphilis thinly disguised as "S." It is a pity that the recent Act of the Indian Government to repress seditious newspapers cannot be made to include prints which thrive on such dirty money as is brought in by lying and indecent advertisements. As for J. W. Wilson and Co. of Madras, we can only say if they are justly entitled to the description of "dispensing chemists" their methods are likely to bring an honourable calling into serious discredit in India. We are informed that this paper was circulated *gratis* as a specimen copy; it is to be hoped that no woman's eyes were insulted by it.

THE PECKHAM NURSING ASSOCIATION.

Mr. H. C. Gooch, M.P., has warmly commended the work of this association on the occasion of a recent drawing-room sale of work in aid of its funds. It was, he said, a relief as well as a pleasure to take part in proceedings in which political bias was unknown. He was sure that those of all shades of opinion would gladly join in doing their utmost to extend the usefulness of the association, which during the past eight years had paid as many as 23,676 visits to over 1000 poor patients. The work of the skilled trained nurses has been most valuable in the large and populous district of Peckham, and he sincerely hoped that the association would receive that increase of financial support which it so sorely needed. The Mayor of Camberwell said that Peckham was greatly indebted to Mrs. Charles Ward (Bixley House, Peckham Rye) who founded the work in 1900. The association, in his opinion, was one of the worthiest in the borough. He pointed out that it ministered not only to the needs of the very poor but also attended cases of sickness and operations among the middle classes for a moderate fee. A number of local clergymen and ministers also spoke of the great value of the association's constant and beneficent efforts.

THE VEGETARIAN FEDERAL UNION.

The annual congress in connexion with this union was held on June 17th to 20th in London, and was inaugurated by a dinner held at the Holborn Restaurant on June 17th under the auspices of the London Vegetarian Association. Mr. E. H. J. Frost presided and addresses were given by Mrs. McDouall and Mr. C. W. Forward. Many thoughtful people will sympathise with vegetarians in their efforts to popularise fruits and vegetables as articles of diet, and a right note was struck by a speaker during the proceedings of the congress at the Memorial Hall, Farringdon-street, E.C., on June 19th, who said that the real question which had to be faced was the discovery of the proper foods to build up the body according to temperament. Although the speaker would probably not admit of other than so-called vegetarian articles of diet it is a healthy sign that the aggressive attitude adopted by most "reformers" of stigmatising all who do not agree with them as being unregenerate shows promise of modification by "food reformers."

Fairplay.—The question of residence within the district over which such appointments have jurisdiction is a very difficult one. The Local Government Board is believed to view out-living with disfavour, but, as far as we know, has given no ruling on the matter in any particular case. In these circumstances a public protest would be inadvisable. The case seems a hard one.

I.M.S.—The specific in question was a quack article of no value and its manufacture has, we believe, now ceased.

Sanitas has raised an interesting point which shall receive our attention.

Communications not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

Saturday.—2.30 p.m., Operations. Medical and Surgical Wards.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince o Wales's General Hospital, Tottenham, N.

Monday.—Clinics:—10 a.m., Surgical Out-patient (Mr. J. H. Evans). 2.30 p.m., Medical Out-patient (Dr. Whipham); Nose, Throat, and Ear (Mr. Carson); X Rays. 4.30 p.m., Medical In-patient Clinic (Dr. Whiting).

Tuesday.—Clinic:—10 a.m., Medical Out-patient (Dr. Auld). 2.30 p.m., Surgical Operations (Mr. Carson). Clinics:—Surgical (Mr. Edmunds); Gynæcological (Dr. Giles). 4 30 p.m., Demonstration of Selected Surgical Cases (Mr. H. Evans).

Wednesday.—Clinics:—2.30 p.m., Medical Out-patient (Dr. Whipham); Skin (Dr. Meachen); Eye (Mr. Brooks).

Thursday.—2.30 p.m., Gynæcological Operations (Dr. Giles). Clinics:—Medical Out-patient (Dr. Whiting); Surgical (Mr. Carson); X Rays. 3 p.m., Medical In-patient (Dr. Chappel). 4.30 p.m., Throat Operations (Mr. Carson).

Friday.—10 a.m., Clinic:—Surgical Out-patient (Mr. J. H. Evans). 2.30 p.m., Surgical Operations (Mr. Edmunds). Clinics:—Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 p.m., Medical In-patient (Dr. R. M. Leslie).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

Monday.—2 p.m., Operations. 2.15 p.m., Sir Dyce Duckworth: Medicine. 4 p.m., Mr. L. A. Lawrence: Ear and Throat. Out-patient Demonstrations:—10 a.m., Surgical and Medical. 12 noon, Ear and Throat.

Tuesday.—2 p.m., Operations. 2.15 p.m., Dr. R. T. Hewlett: Medicine. 3.15 p.m., Mr. McGavin: Surgery. 4 p.m., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 a.m., Surgical and Medical. 12 noon, Skin.

Wednesday.—2 p.m., Operations. 2.15 p.m., Dr. F. Taylor: Medicine. Out-patient Demonstrations:—10 a.m., Surgical and Medical. 11 a.m., Eye.

Thursday.—2 p.m., Operations. 2.15 p.m., Dr. G. Rankin: Medicine. 3.15 p.m., Sir W. Bennett: Surgery. 4 p.m., Mr. M. Davidson: Radiography. Out-patient Demonstrations:—10 a.m., Surgical and Medical. 12 noon, Ear and Throat. 2.30 p.m., Special Lecture:—Dr. Rankin: Myxœdema.

Friday.—2 p.m., Operations. 2.15 p.m., Dr. R. Bradford: Medicine. 3.15 p.m., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 a.m., Surgical and Medical. 12 noon, Skin.

Saturday.—2 p.m., Operations. Out-patient Demonstrations:—10 a.m., Surgical and Medical. 11 a.m., Eye.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Lecture:—Mr. Ballance: Surgery of the Nervous System.

FRIDAY.—3.30 P.M., Lecture:—Dr. A. Turner: Treatment of Epilepsy.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (29th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), West London (2.30 P.M.).

TUESDAY (30th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.).

WEDNESDAY (1st).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2 30 P.M.).

THURSDAY (2nd).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.).

FRIDAY (3rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (4th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1908, which is completed with the issue of to-day, will be given in the next number of THE LANCET.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1908 will be ready shortly. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half year's numbers are now ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach *THE LANCET* Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to *THE LANCET* Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

During the week marked copies of the following newspapers have been received:—*Perthshire Advertiser, Banbridge Chronicle, The Ardrossan and Saltcoats Herald, Reading Mercury, Westminster Gazette, Electrical Review (New York), Broad Arrow, Army and Navy Gazette, Nottingham Guardian, Northern Mail, Wimbledon Gazette, Wimbledon Boro' News, Daily Chronicle, Daily News, Yorkshire Post, Liverpool Courier, Scientific American (New York), Belfast Whig, Glasgow Herald, Pall Mall Gazette, Bedford Times, &c.*

Communications, Letters, &c., have been received from—

A.—Dr. Francis J. Allan, Lond.; Messrs. Armour and Co., Lond.; Messrs. C. G. Adams and Co., Lond.; Addenbrooke's Hospital, Cambridge, Secretary of.

B.—Mr. E. Baker, Birmingham; Messrs. Bedford and Co., Lond.; Birmingham Maternity Hospital, Hon. Secretary of; Mr. S. Bill, Manningtree; British Antitoxine Manufacturing Co., Lond., Secretary of; Mr. J. F. Briscoe, Alton; Mr. W. H. Battle, Lond.; Mr. Frank Townend Barton, Lond.; Messrs. D. Brown and Son, Lond.; Board of Agriculture and Fisheries, Lond., Secretary of; Dr. W. H. B. Brook, Lincoln; Mr. A. A. Bradburne Southport; Mr. F. A. Brockhaus, Lond.; Blackburn and East Lancashire Infirmary, Secretary of; Messrs. Burroughs, Wellcome and Co., Lond.; Messrs. J. Beal and Son, Brighton; Messrs. Blundell and Rigby, Lond.; Dr. G. Granville Bantock, Pinner; Messrs. Sutton Bendle and Co., Lond.

C.—Mr. F. W. Collingwood, Lond.; Messrs. Callard and Co., Lond.; Messrs. Clive and Co., Lond.; Messrs. Crossley and Co., Lond.; Central London Throat and Ear Hospital, Secretary of; Coventry and Warwickshire Hospital, Secretary of; Cape of Good Hope, Trades Commissioner for the, Lond.; Dr. O. J. Currie, Pietermaritzburg; Children's Country Holiday Fund, Lond., Secretary of; Continental Tyre and Rubber Co., Lond.; Chester Corporation, Clerk to the; Mr. John Collingridge, Lond.

D.—Dr. E. H. Douty, Paris; Mr. J. H. Dudgeon, Workington; Mr. A. T. Duka, Bournemouth; Dr. J. L. Dickie, Birmingham.

E.—Dr. J. W. H. Eyre, Lond.; Messrs. Elliott, Son, and Boyton, Lond.; Mr. Frederic Eve, Lond.; Evolutionist.

F.—Dr. F. E. Fremantle, Lond.; Dr. E. Fuld, Berlin; Fair Play; Mr. B. P. Frankfort, Amsterdam; Mr. H. A. T. Fairbank, Lond.; Messrs. Fussell and Co., Lond.; Dr. P. Frank, Lond.; Finsbury Distillery Co., Lond., Manager of; Messrs Flynn and Co., Cork; Dr. P. Ferrerolles, La Bourboule.

G.—Mr. H. Tyrell Gray, Lond.; Dr G Lovell Gulland, Edinburgh; Mr. Archibald E. Garrod, Lond.; Mr. H. M. W. Gray, Aberdeen; Gt Eastern Railway Co., Lond., Continental Traffic Manager of; Mrs. Gihon, Harrogate; G. H.; The Gaggenau Motor Vehicles Co., Lond., Manager of.

H.—Dr. Otto Holst, Eastbourne; Dr. W. J. Howarth, Derby; Mr. Somerville Hastings, Lond.; Colonel E. S. Hastings, Lond.; Mr. H. C. Highton, Lond.; Surgeon Lawrence Hunt, R.N.; Dr. Walter K. Hunter, Glasgow; Mr W. E. Harvey, Portsmouth; Hertford General Infirmary, Resident Medical Officer of; Mr. T. Holland, New York; Messrs. Chas. Hearson and Son, Lond.; H. S.; Horton Infirmary, Banbury, Assistant Secretary of; Messrs. C. J. Hewlett and Son, Lond.; Mr. Cyril Horsford, Lond.

J.—Mrs. Violet Jones, Standford Dingley; J. C. C.; Mr. L. J. Jarvis, Lond.

K.—Dr. H. Cameron Kidd; Bromsgrove; Mr. Skene Keith, Lond.; Messrs. Knoll and Co., Lond.; King Edward VII. Sanatorium, Lond., Hon. Secretary of; Dr. E. Klein, Chislehurst; Messrs. S. Kutnow and Co., Lond.; King Edward's Hospital Fund for London, Hon. Secretaries of.

L. Mr. John Lentaigne, Dublin; Mr. Ernest Leitz, Lond.; Liverpool Stanley Hospital, Secretary of; Lauvaasen Hoifields Sanatorium, Gudbrandsdalen, Norway; Leeds Public Dispensary, Secretary of.

M.—Mr. C. A. Moore, Lond.; Dr. D. Mackenzie, Bowmore; Mr. Horace B Marshall, Lond.; Messrs. C. Mitchell and Co., Lond.; Malling Place, Kent, Medical Superintendent of; Messrs. Maple and Co., Lond.; Manchester Medical Agency, Secretary of; Maltine Manufacturing Co., Lond; Messrs. J. McKenna and Son, Belfast; Mr. E. Merck, Lond.; Manchester Corporation, Clerk to the.

N.—Mr. C. A R. Nitch, Lond.; Dr. David Nicolson, Camberley; Mr. Arthur J. Nettleship, Barton-on-the-Heath; Nottingham Children's Hospital, Secretary of; Northampton County Asylum, Clerk to the; Mr. H. Needes, Lond.; Mr. J. C. Needes, Lond.; National Association for the Prevention of Consumption, &c., Lond., Hon. Secretary of.

P.—Pasteur Vaccine Co., Paris; Messrs. Parkins and Gotto, Lond.; Peckham Nursing Association, Hon. Secretary of; Paris, Lyons, and Mediterranean Railway, Lond.; Mr. F. T. Pain, Lond.; Messrs. Peacock and Hadley, Lond.

R.—Mr. Henry Rundle, Southsea; Royal Buckinghamshire Hospital, Aylesbury, Secretary of; Radcliffe Infirmary, Oxford, Secretary of; Royal Society of Arts, Lond, Council of; Royal Sanitary Institute, Lond., Secretary of; Royal College of Physicians, Edinburgh, Secretary of; Royal Mineral Water Hospital, Bath, Registrar of; Messrs. J. Robertson and Co., Edinburgh; Mr. W. C. Rivers, Northwood; Royal Mail Steam Packet Co., Lond., Secretary of; Royal College of Surgeons in Ireland, Registrar of; Dr. F. Raymond, Lond.; Messrs. E. J. Reid and Co, Lond.; Royal Society of Medicine, Lond., Secretary of; Messrs. Reynolds and Branson, Leeds.

S.—Mr. S. C. Stewart, Sutton; Sir James Sawyer, Birmingham; Mr. S E Sutcliffe, Knowl; Messrs. G. Street and Co., Lond.; Dr. D. Shannon, Glasgow; Dr. H. Simpson, Deganwy; Mr. Hugh Stott, Lewes; Mr. A. F. Stokes, Saunton Sands; Sanitas; Society of Authors (Incorporated), Lond., Secretary of; Mr. R. E. P. Squibbs, New Lenton; Dr. A. H. Stokes, Lond.; Sanitas Electrical Co., Lond.; Society of Apothecaries of London, Secretary of; *South Wales Argus*, Newport, Manager of; Smith's Advertising Agency, Lond.; Dr. T. D. Savill, Lond.; Dr. P. Blaikie Smith, Alford; Scholastic, Clerical, &c., Association, Lond.; Star Engineering Co., Wolverhampton; Messrs. W. H. Smith and Son, Lond.

T.—Miss M. L. Tyler, Lond.; Mrs E. M. Tilbrook, Lond.; Mr. F. C. Turner, Lond.

V.—Dr. Louis Vintras, Brighton; Messrs. J. W. Vickers and Co., Lond.; Mr. J. C. Van Langendonck, Brussels.

W.—Dr. W. J. Wilson, Belfast; Dr. David Walsh, Lond.; Messrs. F. Williams and Co., Lond.; Dr. Leonard Williams, Lond.; West London Hospital Post-Graduate College; Weston-super-Mare Hospital, Clerk to the; Dr. G M. Wilson, Capelulo; Woodhall Spa Co., Woodhall Spa, Secretary of; Messrs A. Wulfing and Co., Lond.; Messrs. Willing and Co., Lond.; Dr. Ernest Watt, Hamilton; Western General Dispensary, Lond., Secretary of.

Z.—Messrs. C. Zimmermann and Co., Lond.; Messrs. A. and M. Zimmerman, Lond.

Letters, each with enclosure, are also acknowledged from—

A.—Ardath Tobacco Co., Lond.; *A. H. M. S.*; *A. F.*

B.—Dr. A. G. Bagshawe, Lond.; Mr. P. Blake, Dundalk; Captain C. R. Bakhle, I.M.S., Bijapur; Messrs. Boots, Nottingham; Burntwood Asylum, Lichfield, Medical Superintendent of; Burton-on-Trent Infirmary, Hon. Secretary of; Mr. C. Basan, Lond.; *Bootle Corporation*, Cashier of Education Committee.

C.—Mr. G. J. Cressy, Woking; Dr. C. H. Cattle, Nottingham; Messrs. *Carters*, Lond.; *C. G.*; Mr. F. W. Clarke, Chorlton-cum-Hardy.

D.—Mr. R. W. Doyne, Lond.; Messrs. Drew and Son, Richmond; Dunelm, Liverpool; Dr. Jean Dardel, Aix-les-Bains; D. J. T.; Devonshire Hospital, Buxton, Secretary of; Mr. C. E. Day, Coniston.

E.—E. R.; E P.

F. Dr. H. S. Frakes, Manchester; Dr. D. C. L. Fitzwilliams, Lond.; F. C. A.; Messrs. L. Farmer and Son, Lond.; Mr. G. Ferrero, Turin; F. B. L.; Mr. F. T. Fagge, Llanfairfechan; Flintshire Education Committee, Mold, Secretary of.

G.—Dr. J. H Griffiths, Woolwich; Messrs. Gilyard Bros., Bradford; G. S., Alexandra Park; Dr. V. R. Gorakshakar, Hyderabad; Dr. H. W. Gardner, Shrewsbury; Messrs. Gould and Portman, Lond.; Messrs. Giles, Schacht, and Co., Bristol.

H.—Mr. J. Heywood, Manchester, H. P. M.; Dr. A. Haig, Lond.; Dr. S. H. Habershon, Lond.; Mr. H. Hancock, Lond.; H. R. D.; Mr. M. Hidayatullah, Jhelam; Mr. J. Hourston, Papa Westray.

I.—Hon. Mrs. Ives, Halstead.

J.—Mr. W. A. James, Lond.; Mr. W. Johnson, Northallerton; J. R. B.; J. H. L. A.; Miss Jackson, Lond.; Mr. D. Jacobs, Lond.

K.—Mr. E. M. Knott, Sutton Coldfield; Dr. T. P. C. Kirkpatrick, Dublin.

L.—Mr. H. K. Lewis, Lond.; Dr. Lazarus-Barlow, Lond.; Captain J. C. Holdich Leicester, I.M.S., Bhowanipur.

M.—Dr. W. J. Mackinnon, Biggar; Messrs. Matthew Bros., Lond.; Mr. B. J. Mayne, Carn Brea; Mental Nurses' Co-operation, Lond., Secretary of; Dr. R. E. Maples, Degama, West Africa; Messrs. Moore and Co., Lond.; Mr. T. F. Meldrum, Altrincham; Mr. W. W. Maxwell, Thames Ditton; Mr. Alexander Morrison, Torquay.

N.—Dr. P. C. Nandi, Calcutta; Mr. F. W. North, Grantham; Dr. R. G. Nothwanger, Newcastle-on-Tyne; Nottingham General Hospital, Secretary of; Northumberland County Education Committee, Newcastle-upon-Tyne, Accountant to the; Messrs. Nicolay and Co., Lond.; North Riding Infirmary, Middlesbro', Secretary of; *Newport* and Monmouthshire Hospital, Secretary of.

O.—Dr. A. W. Oxford, Lond.; Mr. H. C. *Orton*, Lond.; Oldham Guardians, Clerk to the; Mr H. Ohme, Christiania.

P.—Portsmouth Borough Asylum, Medical Superintendent of; Dr. L. C. A. *Pinho*, Bahia; Mr. C. E. Paget, Northampton; Messrs. Potters, Lond.

R.—Messrs. Rebman, Lond.; R. P., Lond.

S.—Miss C. Spicer, Woodford; Messrs. Spiers and Pond, Lond.; South Devon and East Cornwall Hospital, Plymouth Secretary of; St. George's Nauheim Institution, Lond., Secretary of; S. D. S.; S. A. S.; Saarbach's News Exchange, Mainz.

T.—Mr. J. Thin, Edinburgh; T. H. A.; T. C. F.; Mrs. Thompson, Ashby-de-la-Zouche.

V.—Virol, Lond., Secretary of.

W.—Dr. R. L. Woollcombe, Dublin; W. L; W. A. G.; Worcestershire County Council, Worcester, Financial Clerk of; Messrs. W. Wood and Co., New York; Mr. S. Walters Lond.; Winnipeg Bookbindery Manager of; Wolverhampton, &c., General Hospital, Secretary of; Messrs. Wilson and Son, Lond.; Wesleyan Methodist Missionary Society, Lond., Deputy Treasurer of.

Y.—Mrs. York, Earl Shilton; Messrs. Douglas Young and Co., Lond.

The Croonian Lectures

ON

INBORN ERRORS OF METABOLISM.

Delivered before the Royal College of Physicians of London on June 18th, 23rd, 25th, and 30th, 1908,

By ARCHIBALD E. GARROD, M.A., M.D. Oxon., F.R.C.P. Lond.,

ASSISTANT PHYSICIAN TO, AND LECTURER ON CHEMICAL PATHOLOGY AT, ST. BARTHOLOMEW'S HOSPITAL; SENIOR PHYSICIAN, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

LECTURE I.

Delivered on June 18th, 1908.

General and Introductory.

Mr. President and Fellows,—It is my first agreeable duty to offer my sincere thanks for the honour conferred upon me in the invitation to deliver the Croonian lectures of the current year before this College. I trust that the subject which I have selected will be found to conform closely to the instructions to the lecturer, for it is one which lies upon the very border-line of physiology and pathology and pertains to both sciences alike; nor is it without bearing upon the control and cure of disease, in so far as no study which helps to throw light upon the complex chemical processes which are carried out in the human organism can fail in the long run to strengthen our hands in the combat with the pathogenic influences which make for its destruction.

The differences of structure and form which serve to distinguish the various genera and species of animals and plants are among the most obvious facts of nature. For their detection no scientific training is needed, seeing that they cannot escape the notice of even the least cultivated intelligence. Yet with the growth of knowledge we have learned to recognise the uniformity which underlies this so apparent diversity and the genetic relationship of form to form. With regard to the chemical composition of the tissues of living organisms and the metabolic processes by which those tissues are built up and broken down, the advance of knowledge has been in the opposite direction, and the progress of chemical physiology is teaching us that behind a superficial uniformity there exists a diversity which is no less real than that of structure, although it is far less obvious. The differences of ultimate composition and crystalline form which distinguish the hæmoglobins of animals of distinct genera have long been known. That the fats of animals are not alike in composition is well recognised, as also are the differences of their bile acids, to quote only a few of the most conspicuous examples. As instances of distinctive end-products of metabolism may be mentioned kynurenic acid, which is present in the urine of animals of the canine tribe and which bears witness to a generic peculiarity in the manner of dealing with the tryptophane fraction of proteins, and the excretion by birds and reptiles of the bulk of their nitrogenous waste in the form of uric acid, whereas in the urine of mammals urea is the chief nitrogenous constituent.

A more extended study even by strictly chemical methods will doubtless serve to reveal innumerable minor differences, such as are foreshadowed by Przibram's[1] work on muscle proteins. The delicate ultra-chemical methods which the researches of recent years have brought to light, such as the precipitin test, reveal differences still more subtle, and teach the lesson that the members of each individual species are built up of their own specific proteins which resemble each other the more closely the more nearly the species are allied. Obviously it is among the highly complex proteins that such specific differences are to be looked for rather than in the simple end-products of their disintegration. The many amino-acids which enter into the structure of the protein molecules are capable of almost innumerable groupings and proportional representations, and each fresh grouping will produce a distinct protein; but all alike in their breaking down will yield the same simple end-products, urea, carbon dioxide, and others.

Nor can it be supposed that the diversity of chemical structure and process stops at the boundary of the species, and that within that boundary, which has no real finality, rigid uniformity reigns. Such a conception is at variance with any evolutionary conception of the nature and origin of species. The existence of chemical individuality follows of necessity from that of chemical specificity, but we should expect the differences between individuals to be still more subtle and difficult of detection. Indications of their existence are seen, even in man, in the various tints of skin, hair, and eyes, and in the quantitative differences in those portions of the end-products of metabolism which are endogenous and are not affected by diet, such as recent researches have revealed in increasing numbers. Even those idiosyncrasies with regard to drugs and articles of food which are summed up in the proverbial saying that what is one man's meat is another man's poison presumably have a chemical basis.

Upon chemical as upon structural variations the factors which make for evolution have worked and are working. Evidences of this are to be detected in many directions, as, for example, in the delicate selective power of the kidneys, in virtue of which they are enabled to hold back in the circulation the essential proteins of the blood but at the same time allow free passage to other proteins which are foreign to the plasma, such as hæmoglobin, egg albumin, and the Bence-Jones protein, when these are present in any but quite small amounts. The working of these factors is also seen in the various protective mechanisms against chemical poisons, such as that which averts the depletion of the fixed alkalies of the organism by the neutralisation of abnormal supplies of acids by ammonia. This mechanism is well developed in the carnivora and in man, but in vegetivorous animals which from the nature of their diet are little exposed to acidosis it appears to be wanting.

Even in the normal metabolic processes the working of such influences may be traced, as in the power which the organism possesses of destroying the benzene ring of those aromatic amino-acids which enter into the composition of proteins and cannot therefore be regarded as substances foreign to the body; whereas the benzene ring of foreign aromatic compounds, with very few exceptions, are left intact, and such compounds require to be rendered innocuous by being combined with sulphuric acid to form aromatic sulphates, or with glycocoll to form the acids of the hippuric group and so combined are excreted in the urine and got rid of. The few exceptions referred to are compounds which so closely resemble the protein fractions in their structure that they fall victims with these to the normal destructive processes.

The great strides which recent years have witnessed in the sciences of chemical physiology and pathology, the newly-acquired knowledge of the constitution of proteins and of the part played by enzymes in connexion with the chemical changes brought about within the organism, have profoundly modified our conceptions of the nature of the metabolic processes and have made it easier to understand how these changes may differ in the various genera and species. It was formerly widely held that many derangements of metabolism which result from disease were due to a general slackening of the process of oxidation in the tissues. The whole series of catabolic changes was looked upon as a simple combustion and according as the metabolic fires burnt brightly or burnt low the destruction of the products of the breaking down of food and tissues was supposed to be complete or imperfect. A very clear setting forth of such views will be found in the lectures of Bence Jones[2] on Diseases of Suboxidation, delivered and published in 1855, but the thesis in question is chiefly associated with the name of Bouchard,[3] who expounded it in his well-known lectures on Maladies par Ralentissement de la Nutrition, published in 1882. The so frequent clinical association of such maladies as gout, obesity, and diabetes was involved in its support, nor was it regarded as a serious obstacle to the acceptance of such views that there is but scanty evidence to show that failure to burn any particular metabolic product, such as glucose, is associated with inability to deal with others.

Nowadays, very different ideas are in the ascendant. The conception of metabolism in block is giving place to that of metabolism in compartments. The view is daily gaining ground that each successive step in the building up and breaking down, not merely of proteins, carbohydrates, and fats in general, but even of individual fractions of proteins and of individual sugars, is the work of special enzymes set apart for each particular purpose. Thus the notion of general suboxidation is reduced to very narrow limits, to the recognition of a controlling influence exercised by certain glandular organs, such as the thyroid, upon metabolism as a whole. For example, it is known that lævulose is not dealt with in the human organism in the same way as dextrose is but follows its own path. A patient whose power of burning dextrose is seriously impaired may yet utilise lævulose in the normal manner. Again, there is evidence to show that the several fractions of proteins, tyrosin, cystin, tryptophane, and the rest, do not merely serve as fuel for a common furnace but are dealt with each in a special manner and in successive stages.

[3] Maladies par Ralentissement de la Nutrition, Paris, 1882.

It may well be that the intermediate products formed at the several stages have only momentary existence as such, being subjected to further change almost as soon as they are formed; and that the course of metabolism along any particular path should be pictured as in continuous movement rather than as series of distinct steps. If any one step in the process fail the intermediate product in being at the point of arrest will escape further change, just as when the film of a biograph is brought to a standstill the moving figures are left foot in air. All that is known of the course of catabolism tends to show that in such circumstances the intermediate product in being is wont to be excreted as such, rather than that it is further dealt with along abnormal lines. Indeed, it is an arguable question whether, under abnormal conditions, the metabolic processes are ever thrown out of their ordinary lines into entirely fresh ones, with the result that products are formed which have no place in the normal body chemistry. It is commonly assumed that this happens, but if the conception of metabolism in compartments, under the influence of enzymes, be a correct one, it is unlikely, *a priori*, that alternative paths are provided which may be followed when for any reason the normal paths are blocked. It is far easier to suppose that in such circumstances normal intermediate products are excreted without further change and that processes which in health play but small parts in metabolism are called into unwonted activity.

This conception of the permanency of the metabolic paths is no new one, for it may be read between the lines in the writings of some physiologists of the last century, and especially in those of Claude Bernard,[4] from which the following passage is translated:—

> It used to be supposed that in diabetes wholly new conditions were developed in the economy, under the influence of the morbid state, and that there resulted therefrom a special morbid product—namely, glucose. But it is admitted nowadays that the observed phenomena are to be explained by an augmentation, pure and simple, of a normal function in virtue of which glucose is formed in all subjects, even in health. It is clear that the malady is nothing more than a physiological phenomenon perturbed and exaggerated.

Still more striking is the following passage[5]:—

> Et maintenant oserait on soutenir qu'il faut distinguer les lois de la vie à l'état pathologique des lois de la vie à l'état normal? Ce serait vouloir distinguer les lois de la mécanique dans une maison qui tombe, des lois de la mécanique dans une maison qui tient debout.

To prove the truth of the contention put forward it would be necessary to show that every abnormal product found in the tissues or in the excreta, under morbid conditions, can be ascribed to other causes than the deflexion of the metabolic processes into new and unwonted paths. It must be admitted that this cannot yet be asserted of all such products. For example, we are still ignorant of the parent substance and mode of origin of the remarkable Bence Jones protein which is excreted in the urine of patients with multiple myeloma, nor is there any evidence as yet forthcoming that it is a normal intermediate product of protein metabolism. Nevertheless, when an endeavour is made to classify the unusual constituents which are occasionally present in that most important animal excretion, the urine, it is found that there are few of them which cannot be accounted for as intermediate products incompletely burnt, or as exaggeration of traces normally present; if we exclude such as are merely foreign substances absorbed from the alimentary canal or derivatives of these, or are products of bacterial life and action in the intestines or in the tissues.

A number of unusual constituents of urine, and of normal constituents also, are derived from the alimentary canal. Thus foreign substances administered in food or as drugs may be excreted unchanged or may undergo oxidation or reduction in the intestine or after absorption, or again may appear in the urine in combination with products of metabolism. These last compounds, which result from the working of the chemical protective mechanisms, cannot be regarded as abnormal excreta. Even in health some tenth part of the total sulphuric acid of the urine is in combination with aromatic substances as ethereal sulphates. Traces of compound glycuronates are also normally present, and the aromatic constituents of vegetable foods are in part excreted in combination with glycocoll as hippuric acid and its allies. When other harmful substances, with which these protective mechanisms are competent to deal, are introduced in abnormal quantities the protective processes are stimulated to unwonted activity.

It does not necessarily follow that the substances which are utilised for such combinations are themselves intermediate products of normal metabolism, for it may well happen that combination has preceded oxidation. Thus the glycuronic acid which is excreted in compound glycuronates may not represent an intermediate stage in the breaking down of glucose as it has been supposed to do, for, as Emil Fischer has pointed out, the oxidation of the alcohol grouping of dextrose, whilst the less stable aldehyde grouping remains intact, is more easily explained on the supposition that the primary combination of the foreign substance is with glucose itself, and that, the aldehyde group being thus protected from change, oxidation to glycuronic acid occurs as a subsequent event.

Some excreta are due to the action of bacteria in the alimentary canal upon the proteins of food or upon constituents of the bile. Thus urobilin is formed by the intestinal bacteria from bilirubin and is abundantly present in the fæces so long as bile enters the intestine. From the intestine some urobilin is absorbed and is excreted in part in the bile and in part in the urine, whilst some of it is probably destroyed in the tissues. Again, from the tryptophane of ingested proteins the intestinal bacteria form indol, which after absorption is oxidised to indoxyl and is excreted in the urine, mainly as indoxyl sulphate, but in part in combination with glycuronic acid. Disease of the actual organs of excretion has conspicuous effects upon the excreta. Thus diseased kidneys may hold back in part some constituents of the urine or, on the other hand, may allow passage to the normal proteins of the blood serum which it is their function to retain in the circulation. Again, by the blockage of a duct, as in jaundice, the products of glandular activity may be thrown back into the blood and appear in the urine, but the presence of such abnormal constituents is in no sense due to errors of metabolism.

Actual derangements of the metabolic processes follow almost any deviations from the normal health, but our interpretation of the urinary changes which result is in many instances greatly hampered by the scantiness of our knowledge of the intermediate steps of the paths of metabolism. Such knowledge as we have of these steps is derived from casual glimpses afforded when, as the outcome of one of Nature's experiments, some particular line is interfered with, and intermediate products are excreted incompletely burnt. Many of the substances which rank as abnormal constituents are present in traces in normal urine as by-products of the metabolic processes, and it may safely be assumed that we are not cognisant of all the traces which so occur. Exceptional methods will reveal traces previously unsuspected. Thus Dombrowski, working with enormous volumes of normal urine (100 litres), was able to demonstrate the presence of minute quantities of cadaverin; and that very delicate instrument the spectroscope reveals traces of hæmatoporphyrin in normal urine which would escape detection by rougher means. Only recently it has been shown that certain sulphur-containing acids, previously unknown, occur in no inconsiderable quantities in normal urine, and even now we do not know with any certainty all the constituents which go to make up the so-called neutral sulphur and residual nitrogen.

The effects of disease of the great laboratory glands, of which the liver is the chief, upon the chemical processes of which they are the seats, are less conspicuous than might be expected. This is perhaps due to the power of a small intact residue of an organ to carry on the functions of the whole, nor must it be forgotten that any very grave interference with the metabolic activities of the liver is incompatible with life. On the other hand, the phenomena of exophthalmic goitre and of myxœdema bear witness to the profound effects of atrophy or disease of a gland which exerts a controlling influence over the metabolic processes as a whole. Some abnormal constituents of urine are believed to be products of undue breaking down of tissues, of autolysis *intra vitam*. Such an origin is now usually ascribed to the tyrosin and leucin excreted in acute yellow atrophy of the liver, and to the albumoses met with in urine.

[4] Pathologie Expérimentale, second edition, 1880, p. 15.

[5] Ibid., p. 563.

There is a group of maladies in which metabolic disturbances are by far the most conspicuous features, whereas the structural changes behind them are scanty or even inappreciable. Of such "diseases of metabolism," diabetes, gout, and obesity are the most important. It is still uncertain how far the accumulation of uric acid in the blood and the deposition of sodium biurate in the tissues which are the characteristic features of gout, are actually due to derangement of metabolism, as distinct from a mere excretory defect. In diabetes mellitus, under which name we probably include more than one morbid condition attended by persistent glycosuria, the metabolic derangements, primary and secondary, dominate the clinical picture. At the outset sugar may be excreted in very small quantity and only after a meal rich in carbohydrates; at a later stage the glycosuria tends to become continuous and the percentage of glucose in the urine rises until, in grave cases, the excretion almost ceases to be controlled by diet and the tissue proteins are called upon to supply sugar. By the destruction of fats and proteins the acetone bodies and especially β-oxybutyric acid are formed in increasing amounts, and to them the fatal ending is commonly attributed at the present day, although the accumulation of unburnt glucose in the blood is itself productive of serious evils. The liability to develop diabetes or gout is often inherited but the diseases themselves are not inherited, for they are never congenital. Developing at any period of life, the mischief, once begun, tends to become aggravated as time goes on, but the rate of aggravation differs widely in individual cases and is often conspicuously controlled by appropriate treatment.

Quite unlike that of the above metabolic diseases is the course of the anomalies of which I propose to treat in these lectures and which may be classed together as inborn errors of metabolism. Some of them are certainly, and all of them are probably, present from birth. The chemical error pursues an even course and shows no tendency to become aggravated as time goes on. With one exception they bring in their train no serious morbid effects, do not call for treatment, and are little likely to be influenced by any therapeutic measures at our disposal. Yet they are characterised by wide departures from the normal of the species far more conspicuous than any ordinary individual variations, and one is tempted to regard them as metabolic sports, the chemical analogues of structural malformations. It is interesting to note that as far back as the earlier years of the nineteenth century, one of them, albinism, was classed by Mansfeld[6] and by Meckel[7] as a "Hemmungsmissbildung" or malformation by arrest.

It may be pointed out that the epithets inborn and congenital are by no means synonymous. Structural abnormalities may be present at birth which owe their origin to intra-uterine disease or intra-uterine injury and are in no sense developmental errors. Again, an infective disease may be congenital but cannot be inborn. It has merely been acquired in utero. Even true developmental errors are of several distinct kinds. In some there is malposition or transposition of organs, partial or complete; in others doubling of parts or inclusion of twin structures. Some structural anomalies are malformations by excess such as polydactyly, and some are malformations by defect, such as absence of the middle phalanx of each digit. In one large class, the so-called malformations by arrest, the process of development meets with a check and some portion of the body is left unfinished. To this group belong such abnormalities as hare lip, cleft palate, and spina bifida. Speaking of such arrests Professor J. A. Thomson writes:[8] "These abnormalities occasionally recur repeatedly in a family tree, but it seems probable that what is really inherited is a deficiency in 'developmental vigour' accentuated by nutritive defects on the parts of the mothers during the period of gestation." No extraneous causes, such as intra-uterine injury or disease, can be assigned to the metabolic errors which are under discussion. As far as our present knowledge of them enables us to judge they apparently result from failure of some step or other in the series of chemical changes which constitute metabolism, and are in this respect most nearly analogous to what are known as malformations by defect. It is not only in the field of metabolism that inborn derangements of function are met with, and Daltonism and night-blindness may be quoted as examples of such anomalies having no obvious chemical basis.

At first sight there appears to be little in common between inborn derangements of function and structural defects, but on further consideration the difference is seen to be rather apparent than real. Almost any structural defect will entail some disorder of function; sometimes this is almost inappreciable, but, on the other hand, the resulting functional disorder may be so conspicuous that it completely overshadows the defect to which it is due. Very slight structural changes may lead to profound functional derangements, as witness the effects of atrophy of the thyroid gland, whether congenital or acquired in later life, and the stormy metabolic disorders which may ensue upon comparatively insignificant morbid changes in the pancreas. By selective breeding there has been produced a race of waltzing mice, but their bizarre dance is merely the functional manifestation of an inborn and hereditary malformation of the semicircular canals. In the same way beneath each chemical sport may well exist some abnormality of structure so slight that it has hitherto escaped detection. Among the complex metabolic processes of which the human body is the seat there is room for an almost countless variety of such sports, but the examples which can be adduced are very few in number. Indeed, up to now the only known anomalies which can, with any good show of reason, be assigned to this class are albinism, alkaptonuria, cystinuria, and pentosuria, and even as regards these the reasons for their inclusion in the group are not of equal cogency.

We should naturally expect that among such abnormalities those would earliest attract attention which advertise their presence in some conspicuous way, either by some strikingly unusual appearance of surface tissues or of excreta, by the excretion of some substance which responds to a test habitually applied in the routine of clinical work, or by giving rise to obvious morbid symptoms. Each of the known inborn errors of metabolism manifests itself in one or other of these ways, and this suggests that others, equally rare, which do not so advertise their presence, may well have escaped notice until now. One man in 20,000 whose urine of 24 hours habitually contained a few grammes of aspartic acid might well be overlooked. Theoretically any anomaly which claims a place in the group should be present from birth and should persist throughout life, but it must be confessed at the outset that this cannot as yet be definitely asserted of all the four metabolic errors which I have mentioned. Some of them produce no obvious effects which compel attention, and may only be accidentally detected in adult life, and neither the evidence of the patient himself nor that of his parents can be of any help in endeavouring to trace back the peculiarity to infancy.

That albinism is congenital and persists through life is self-evident and admits of no dispute, for the condition is as obvious as any structural malformation and much more so than many such. Its rarity in man is also evident, although by artificial selection it may be reproduced indefinitely in lower animals.

As regards alkaptonuria its lifelong persistence is equally well established, although it may be that this error, which is in the great majority of instances inborn, may occasionally occur as a temporary phenomenon in disease. The remarkable staining property of alkapton urine allows of its recognition at the very beginning of life, and I have been able to obtain reliable evidence with regard to two cases that the staining of clothing was noticed on the second day of life, and in one of these instances had an opportunity of examining some urine passed during the first ten days after birth.[9] On the other hand an individual who exhibits the anomaly may reach adult life without being aware of any special peculiarity of his urine and the condition may only attract attention when he is an applicant for life insurance or comes under treatment on account of some illness. Winternitz[10] has recorded the interesting fact that the mother of seven children, three of whom were alkaptonuric, was convinced that whereas two of her children had passed alkapton urine from the earliest days of life, this had not been the case with the youngest child, in whom she had only noticed the peculiarity from the age of five years. Such information supplied by a mother familiar with the symptoms of alkaptonuria carries as much weight as any hearsay evidence can carry, but nothing short of actual chemical examination of the urine would suffice to prove a point of so much importance.

Turning now to cystinuria, the evidence of its congenital occurrence is much more difficult to obtain, for this anomaly is little likely to attract attention in a young infant. Seeing that cystinuria is not infrequently transmitted from parent to child, examination of the urine of the infant children of those who manifest the peculiarity offers the most likely means of settling the point. That it may be present in early childhood there is abundant evidence to show. The first cystin calculus ever examined[11] was taken from the bladder of a child of five years. Abderhalden[12] has placed on record the detection of cystinuria in two children of the same family at the ages of 21 months and 14 months respectively, and Ultzmann[13] the case of a child of two with a cystin calculus who had exhibited symptoms of stone from the age of 12 months. Not a few cases in older children have been described. As affording evidence of the long persistence of cystinuria a case which came under the observation of the late Sir Henry Thompson[14] may be quoted that of an old man, aged 81 years, for whom a cystin calculus was crushed, and who had passed a stone of the same nature 39 years previously. There is reason to believe that cystinuria, like alkaptonuria, is occasionally temporary or intermittent.

No direct evidence of the congenital occurrence of pentosuria, the latest discovered and least known member of the group, is yet forthcoming, and its inclusion is to be justified on other grounds. That it may persist unchanged for years is certain, but the youngest pentosuric yet observed was a boy aged 15 years.[15]

It is probable that the rarity of albinism in man, of which each of us is able to judge from personal observation, is no greater than that of the other inborn errors. My belief is that cystinuria is decidedly the least rare of the four, but C. E. Simon[16] met with only one cystin sediment among some 15,000 urines examined, and Primavera[17] one in 20,000 urines. Another feature which all four anomalies share in common is their more frequent occurrence in males than in females. Of 38 cases of alkaptonuria, presumably congenital, 31 were in males and only seven in females. Of 93 cystinurics collected from the records by Simon 63 were males and 30 females. Of 26 pentosurics, 19 were males and seven females. That males preponderate among albinos has often been stated, but among the cases collected by Ascoleo[18] in Sicily the disparity was comparatively slight, the numbers being 34 males and 28 females. It does not appear that there is any such unequal liability of the sexes to structural malformations, as far as can be judged from figures collected from the records of two hospitals, and in the remarkable family described by Farabee[19] in which many members exhibited a curious malformation by defect—namely, absence of the middle phalanges—the majority of the affected members were females. In a similar family recorded by Drinkwater,[20] male cases slightly preponderated.

To be harmless is no essential attribute of an inborn abnormality, but it stands to reason that an error of metabolism which persists from birth into adult and even into advanced life must needs be relatively innocuous. Albinism, although inconvenient, is certainly harmless, and the most serious direct result of alkaptonuria is the peculiar pigmentation, a variety of ochronosis, which some of its subjects develop in later life. Evidence is accumulating of the harmlessness of pentosuria, and that the excretion of a sugar with five carbon atoms in its molecule has none of the sinister significance of glycosuria. Only cystinuria can be classed as actually injurious, but even its ill-effects, serious as they often are, are not due to the deranged metabolism as such but are secondary, and result from the unsuitability of so sparingly soluble a substance as cystin for excretion by way of a urinary apparatus constructed upon the mammalian plan. Even in the single recorded instances in which death may possibly have resulted from cystinuria, apart from urinary complications, that of an infant aged 21 months, which Abderhalden describes, the deposition of cystin in the tissues was the conspicuous lesion found at the necropsy.

There remains to be mentioned yet another feature which the abnormalities under discussion possess in common—namely, the liability for each of them to occur in several members of a family, most often in collaterals of the same generation. In this respect, of course, they do not stand alone. In connexion with many *actual diseases*, as well as with structural malformations, hereditary influences come into play, and among diseases with none more strikingly than with such metabolic disorders as *diabetes and gout*. Only when taken in conjunction with all the other common features which have already been discussed can their mode of incidence be adduced in support of the view here taken of their nature.

To the students of heredity the inborn errors of metabolism offer a promising field of investigation but their adequate study from this point of view is beset with many difficulties. Save in the case of albinism one is driven to rely upon the casual mating of human beings and the conclusions based thereon cannot be checked by experimental breeding of animals. It is true that cystinuria is known to occur in dogs. A calculus obtained from a dog was described by Lassaigne[21] in 1823, and other examples have since been recorded,[22] but hitherto the diagnosis has only been made after the death of the animal and no opportunity has presented itself of utilising this fact for the advancement of the study of the anomaly. Whether alkaptonuria and pentosuria occur among lower animals is unknown. If they do they are little likely to be recognised.

Again it is naturally far more difficult to collect information as to the occurrence of chemical than of structural anomalies in past generations of a family, save in the case of albinism and possibly of alkaptonuria. Even as regards the relative numbers of normal and abnormal members, a knowledge of which is so important in connexion with questions of heredity, the information available is scanty and unreliable unless based upon personal examination. However, one point which stands out clearly is the remarkable similarity of the modes of incidence of alkaptonuria and albinism, which suggests that the manifestation of both is governed by the same laws. Both are apt to occur in several brothers and sisters of a family whose parents do not exhibit the anomaly and direct transmission of either from parent to child is very rare. It has been repeatedly stated that a considerable proportion of human albinos are the offspring of consanguineous marriages. Thus Ascoleo found that of 24 families which included 60 albino members five were the offspring of the mating of first cousins. In only two instances was albinism directly transmitted from parent to child. Of the cases of alkaptonuria, concerning which the necessary information is forthcoming, a very large proportion have been in children of first cousin marriages. In a paper published in 1902[23] I called attention to this point and more recent cases, although they have somewhat lowered the proportion, have borne out the fact, as will be seen from the following table, in which the more recent cases have been incorporated.

* In some instances private information has supplemented the published records. For some of the more recent cases the required information is not forthcoming. The new references will be found in the bibliography of Lecture II.

Thus of 17 families eight were the offspring of first cousins and nine were the children of parents who were not related, and of the total of 31 cases 15 fall into the first group. There appears to be a close connexion between the occurrence of an anomaly in several children of normal parents and consanguinity of the parents, a connexion which has been emphasised by Feer[24] in a recent paper. No one would suggest nowadays that the mere fact that the parents are of one blood would cause an anomaly to appear *de novo* in their children but it is obvious that the reappearance of a latent character which both parents tend to transmit is likely to be favoured by the mating of members of certain families.

The statistics as to the proportion of first-cousin marriages in this country are very scanty. Sir George Darwin has calculated[25] that less than 3 per cent. of all marriages are of this class, and Professor Karl Pearson[26] has recently collected some figures which give a percentage of 4·9 first-cousin marriages among the professional classes, a figure which for reasons which he states he regards as probably somewhat too high, and 0·86 among the classes from which patients in London hospitals are drawn. The totals of consanguineous marriages of all degrees in the two classes were 7·76 per cent. and 1·3 per cent. respectively. Hence it is obvious that the proportion of such marriages among the parents of alkaptonuric families is altogether abnormal. On the other hand, the proportion of alkaptonurics among children of such marriages must be very small indeed. Only some 50 to 60 cases of alkaptonuria have been recorded in Europe and America, whereas in London alone there are probably many thousands of children of first cousins.

It was pointed out by Bateson,[27] and has recently been emphasised by Punnett,[28] that the mode of incidence of alkaptonuria finds a ready explanation if the anomaly in question be regarded as a rare recessive character in the Mendelian sense. Mendel's law asserts that as regards two mutually exclusive characters, one of which tends to be dominant and the other recessive, cross-bred individuals will tend to manifest the dominant character, but when they interbreed the offspring of the hybrids will exhibit one or other of the original characters and will consist of dominants and recessives in definite proportions. Mendel's theory explains this by the supposition that the germinal cells or gametes of each generation are pure as regards the qualities in question and accounts for the numerical results observed by the production of dominant and recessive gametes in equal numbers. Of the offspring of two hybrids, one quarter will result from the union of two dominant gametes and will produce such gametes only; another quarter will result from the union of recessive gametes and will produce only recessive gametes. The remaining half will themselves manifest the dominant character, but will be hybrids like their parents and will produce gametes of both varieties. Only when two recessive gametes meet in fertilisation will the resulting individual show the recessive character.

If the recessive character be a rare one many generations may elapse before the union of two such gametes occurs, for the families in which they are produced will be few in number and the chance that in any given marriage both parents will contribute such gametes will be very small. When, however, intermarriage occurs between two members of such a family the chance will be much greater, and of the offspring of such a marriage several are likely to exhibit the peculiarity. The rarer the anomaly the more conspicuous should be the influence of consanguinity. When a recessive individual mates with an apparent dominant who produces gametes of both kinds a larger proportion of the offspring will be recessives, and we should expect that recessive children of a recessive parent, but whose other parent is apparently normal, will occasionally be met with. Of such direct transmission of alkaptonuria from parent to child, the other parent not being alkaptonuric, two examples are known. One of these was observed by Osler.[29] An alkaptonuric father whose brother also showed the anomaly had an alkaptonuric son. The second case, which was recorded by Ossi,[30] was that of a mother and her son and daughter, all alkaptonuric. Lastly, when recessive mates with recessive all the offspring should manifest the recessive character, but no such marriage of alkaptonurics is known to have occurred. Whereas in animals, such as mice, which produce a numerous progeny, the proportions of dominants and recessives among their offspring can be readily observed, the results of the chance matings of human beings, who are so far less prolific, are far less demonstrative.

It must be confessed, indeed, that as regards human characteristics the relative numbers of dominant and recessive offspring have often departed widely from these required by Mendel's law, but a number of sources of error will tend to vitiate such results. Experience has shown that the information supplied as to the normality or otherwise of other members of a patient's family can seldom be relied upon, and this is especially the case with chemical anomalies. An individual in middle life seldom knows much about his brothers and sisters who died in infancy. Miscarriages must be taken into account, and again the figures supplied may relate to incomplete families and may be profoundly modified by subsequent births. For the above reason little importance is to be attached to the figures available with regard to alkaptonuria, but those contained in the following table, which relate to 17 families, are given for what they are worth :—

—	Observers.	Total number in family.	Normal members.	Alkaptonuric members.
Family No. 1	F. W. Pavy.	14	10	4
„ 2	Noccioli e Domenici.	10	9	1
„ 3	Ogden.	8	7	1
„ 4	Zimper.	8	6	2
„ 5	Winternitz.	7	4	3
„ 6	Langstein and E. Meyer.	6	5	1
„ 7	Schumm.	6	4	2
„ 8	Garrod.	5	3	2
„ 9	R. Kirk.	4	1	3
„ 10	Bandel.	4	2	2
„ 11	Hammarsten.	4	2	2

„ 16	Garrod and Clarke.	1	0	1
„ 17	Cronvall.	1	0	1
Totals		86	55	31

Although the totals show that the normal members largely preponderate they do not approach the requirements of Mendel's law, according to which a recessive character should appear in one quarter of the offspring; the alkaptonurics should number 21 or 22 instead of 31. It is clear that the figures as they stand are not fair to Mendel, for in the last three families the affected members were only children, and in families 15 and 16 might be classed as first children. One would expect to obtain a more accurate estimate by confining our attention to the larger families, and it is noteworthy that if one takes families 1 to 8, each containing five or more children, the totals work out in strict conformity to Mendel's law, in the proportions 4 : 3 : 1. However, to draw the line at families of five and upwards is a purely arbitrary proceeding.

The patients of Baumann and Embden were a brother and sister born out of wedlock, but it is not quite clear from the record whether they were the only children of the union. Both parents subsequently married away and had children, none of whom were alkaptonuric. Two recorded alkaptonurics were twins and in one case the second twin was certainly and in the other was probably normal.[31] In each instance the normal twin died and the alkaptonuric survived. The twins were of the same sex in both cases.

It appears to me that the strongest argument which can be adduced in favour of this view that alkaptonuria is a Mendelian recessive character is afforded by the fact that albinism, which so closely resembles it in its mode of incidence in man, behaves as a recessive character in the experimental breeding of animals.[32] Nor do the figures quoted by Bateson[33] relating to the proportion of albino members in human families show any more close conformity to the requirements of Mendel's law than do those above quoted for alkaptonuric families.

Evidence is accumulating of the occurrence of pentosuria in brothers and sisters,[34] and no instance of its transmission from parent to child has yet been recorded. Of consanguinity of parents of the subjects of this abnormality nothing is yet known. There is some evidence of a special liability of the Jewish race.

The available evidence regarding the inheritance of cystinuria is much more scanty than that relating to alkaptonuria. This is largely due to the less obvious character of the anomaly, for it is only by careful examination of the urine of each member of a family that any certainty can be reached as to the numbers of cystinuric and normal members. A cystinuric does not necessarily form calculi, and at any given time his urine may deposit no crystals, nor are the statements of patients as to other members of their families of any value in this connexion save that a history of several cases of stone may be suggestive. Such information as is forthcoming points to a greater frequency of direct transmission from parent to child than is met in connexion with the other metabolic errors, and cystinuria has been traced with certainty in three successive generations. Thus in the family investigated by Abderhalden the paternal grandfather and father were cystinuric, whereas the mother was normal. Of five children one had died with symptoms of inanition at 21 months and deposits of cystin were found in its tissues; two others had died with like symptoms at nine and 17 months respectively, but were not known to excrete cystin. The surviving children, aged five and a half years and 14 months respectively, were both cystinuric. Such large proportion of cystinuric members as was here met with has been observed in other families. In one which Cohn[35] described a cystinuric mother and a normal father had 12 children. The urine of two of them could not be obtained, but of the remaining ten no less than seven excreted cystin. Again, Pfeiffer[36] records four children of normal parents who were, as he has informed me, first cousins, all of whom were cystinuric. The two children of one of the affected daughters were normal. The frequency of direct inheritance and the large proportion of the offspring affected suggest that if cystinuria be transmitted on Mendelian lines it is probably a dominant rather than a recessive characteristic.

Hitherto we have been considering these inborn errors of metabolism collectively, the points which they have in common, and the grounds for regarding them as constituting a distinct group of anomalies. But each one of them presents peculiar features of much interest which amply repay detailed consideration, if only on account of the light which their study throws upon the chemical processes at work in the normal human organism.

ALBINISM.

Of albinism I propose to speak very briefly, for its study from the chemical side has scarcely begun. In the fairly extensive literature of the subject much space is devoted to the ocular troubles which are connected with it; some authors have treated of its hereditary aspects; the question whether albinism carries with it any impairment of bodily or mental powers has been widely discussed but the actual nature of the anomaly has hardly been touched upon. Clearly it is an abnormality of a different kind from the others here under discussion which manifest themselves by errors of excretion. In albinism there is a defect of substances which are normal constituents of certain specialised tissues and which serve purposes of much utility to the organism. It is not necessary to enter upon any discussion of the question whether it should be classed as an error of anabolism or of catabolism. The work of F. G. Hopkins[37] upon the utilisation of excretory products in ornament, as exemplified in the employment of uric acid in the pigmentation of white butterflies of the genus Pieris, is of interest in this connexion, but it is probable that in insects, as in birds and reptiles, the excreted uric acid is largely formed by synthesis, as the breaking-down of nuclein does not provide an adequate source for the yield.

The essential phenomenon of albinism is the absence of the pigments of the melanin group which play the chief part in the colouration of man and lower animals and which serve the important function of rendering the eye a dark chamber. There are various kinds of melanins, but all alike are wanting in albinos, as witness the white hair, pink eyes, and unpigmented skin which characterise such individuals. Pigments of other kinds are not wanting, such as the lipochromes which impart their yellow tints to fats and blood serum, and hæmoglobin and its derivatives. In the urine of albinos I have found the same pigments as are ordinarily present. The fact that albinos of certain birds, such as the peacock, which are normally characterised by the brilliancy of the colouring of their plumage, are quite white, does not invalidate the truth of this statement. Their brilliant tints are interference colours, due to physical structure and not to pigmentation, and the absence of such colours is merely due to the lack of a dark background for their display, and such a background the melanins with their sombre hues provide. In the feathers of the albino peacock the iridescent tints are faintly visible in certain lights.

Our knowledge of the chemistry of melanins is still very imperfect. Their sulphur content varies widely; some contain iron, others do not. The presence of iron has been held to indicate an origin from hæmoglobin, but the trend of opinion at the present day is towards the view that they are derived from proteins in general, perhaps by the action of a tyrosinase upon tyrosin, and that the natural melanins are allied to the melanoid substances which are formed during the hydrolysis of proteins. If, as has been suggested, white hair contains a white chromogen and is pigmented and not merely devoid of colour; if also this is true of albino hair as well as that of white animals not albinos, we may suppose that the chromogen merely fails to be converted into the dark pigments in the ordinary way.

Three possible explanations of the phenomenon of albinism suggest themselves. We might suppose that the cells which usually contain pigment fail to take up melanins formed elsewhere; or that the albino has an unusual power of destroying these pigments; or again that he fails to form them. Some experiments of Kobert,[38] who injected solutions of melanin into rabbits, seem to negative the notion of an unusual destructive power. The animals excreted melanin, or rather its chromogen melanogen, in their urine. Kobert mentions that some of the animals injected were albinos, but does not say that they behaved any differently in this respect from the pigmented rabbits. The injection caused no pigmentation of the hair or eyes of albino rabbits, nor is it to be expected that it would do so whichever of the above hypotheses be correct. It is very unlikely that the melanin is conveyed to the pigmented cells and there deposited, for all the evidence available indicates that the pigment is formed *in situ*, probably by the action of intracellular enzymes. If the melanin were formed in albinos and merely not utilised we should expect it to be excreted by them in the urine, which is not the case. Only certain specialised cells appear to have the power of forming melanin, and in cases of melanotic sarcoma these are enormously multiplied, and there is a correspondingly increased production of pigment which may find its way into the blood and be excreted in the urine. Such an increase is only to be explained on the supposition that the pigment is actually formed in the tumour cells. In favour of this view is also the fact that melanotic tumours apparently originate only in structures in which melanins are normally present, such as the eye and skin, and possibly in the pineal gland, which as a vestigial remnant of the pineal eye of certainly lowly animal forms may retain some pigment forming power.

[37] Philosophical Transactions of the Royal Society, 1895, clxxxvi., B. p. 661.

[38] Ueber Melanine, Wiener Klinik, 1901, Band xxvii., p. 99.

The hypothesis of local formation also supplies the easiest explanation of the phenomena of partial or local albinism, such as is seen in the Himalayan rabbit, which has the pink eyes of an albino but the hair of which is always pigmented at certain points. The partial albinism seen in man, in which the hair retains a certain amount of colour, and especially the rare form in which red hair is associated with pink eyes, a variety which has been met with in one albino of several in a family, the others conforming to the ordinary type,[39] is a phenomenon calling for careful investigation.

The ordinary physiological causes of pigmentation are not operative in albinos. In them exposure to the sun does not cause the usual tanning of the skin which is seen in normal individuals; a mere hyperæmia results. It has also been observed that in female subjects the pigmentation of the areolæ of the nipples and of other parts, which usually accompanies pregnancy, is not developed.[40] I know of no observations on the occurrence in albinos of tumours originating in the eye and running the course of melanotic sarcomata. One would expect that such growths, if they occur, would fail to be pigmented. Nor does there appear to be any record of Addison's disease occurring in such subjects which might throw important light upon the question whether the Addisonian pigment is a true melanin. Taking all the known facts into consideration, the theory that what the albino lacks is the power of forming melanin which is normally possessed by certain specialised cells is that which has most in its favour and is probably the true one. If so, an intracellular enzyme is probably wanting in the subjects of this anomaly, an explanation which, as we shall see later, brings albinism into line with some other inborn metabolic errors, of which a similar explanation is at least a possible one.

I must not omit to mention that there are indications that the differences between albinos and normal individuals are not confined to the absence or presence of melanins in the tissues. In animals differences have been observed in the matter of liability to certain infections, and clinical observations of the incidence of infective diseases upon human albinos would be of considerable interest. Halliburton, Brodie, and Pickering[41] found that intra-vascular injections of nucleo-proteins failed to produce in albino animals such clotting as they cause in pigmented ones. G. R. Mudge,[42] who has carried out a number of such experiments, found that all albinos do not behave alike in this respect. Differences were also observed between the results of the injection of nucleo-proteins derived from albino and pigmented animals respectively. He arrived at the conclusion that an albino animal requires a larger dose of nucleo-protein per kilogramme of body weight to cause death by intra-vascular clotting. Pickering's[43] remarkable observation that the Norway hare when in its winter coat behaves as an albino when injected with nucleo-protein, but in its summer coat as a pigmented animal, opens up the most interesting question of the relation, if any, of the change of coat in Arctic animals to albinism.

It will be clear from the above fragmentary sketch that even the lines along which the systematic study of albinism may profitably be directed are only beginning to indicate themselves. The carrying out of such a research remains as a task for future workers.

ON THORACOSTOMY IN HEART DISEASE.

By ALEXANDER MORISON, M.D. EDIN.,
F.R.C.P. LOND. & EDIN.,
PHYSICIAN TO THE GREAT NORTHERN CENTRAL HOSPITAL.

IN a paper published in THE LANCET of July 28th, 1906, and read before the Æsculapian Society of London on April 30th in the same year, I considered the circumstances of the normal growth and action of the heart and the manner in which hypertrophy of the organ is influenced by its adhesion to the pericardial sac and extraneous structures. I remarked in conclusion: "To return to our embryo, the growing organ requires a surplus of room to grow in; the overgrown organ requires more room to work in, and it may be that tethered by extraneous adhesion or not so restricted the hypermyotic heart may in the future, and in some cases, be provided with such by the genius and courage of some surgeon bold enough to undertake the task" (p. 212).

I was not aware until I read Professor Wenckebach's paper on Some Points in the Pathology and Treatment of Adherent Pericardium in the *British Medical Journal* of Jan. 12th, 1907, that Professor Brauer, at that time of Heidelberg, had induced Professor Petersen and Dr. Simon to perform an operation for the relief of cardiac motion in such cases with success so long ago as 1903,[1] and had termed his operation cardiolysis. Dr. William Mackenzie of Melbourne, unaware, like myself, of Brauer's work in cardiolysis, gave very definite instructions for a proposed operation for freeing the heart from costo-pericardial adhesions in the *Intercolonial Medical Journal* of Sept. 20th, 1906. Dr. Mackenzie even advocated removal of a portion of sternum as well as the ribs, a procedure which Dr. Simon adopted in two of Brauer's cases.

It is a subject which has long interested me and in my book on "Cardiac Failure," published in 1897, I had suggested the severing of pericardial adhesions for the relief of cor bovinum which, I stated, would be "an ideal triumph of modern surgery" (p. 88). A reviewer of my book remarked that I had in any case exhibited a "triumph of the imagination," but appeared to be of opinion that the safety of mankind would be consulted by my suggestion not being taken seriously. Since then there has, however, been a growing conviction in my mind that it was less the tethering of the heart than its *bulk* and force of systole which were the determining factors in the situation and that operation to afford room adequate for the free action of the enlarged organ was the primary consideration whether the organ itself were tethered or not. One has so often observed post mortem a large muscular heart usually associated with aortic valvular disease and without extraneous adhesion, succumb to the mechanical difficulty, while possessing apparently an amount of wholesome muscle which one would, *a priori*, have imagined should have contended with the obstacle in the circulation for a much longer period had it not been exhausted by some other cause.

Brauer's suggestion that the adhesions in adhesive pericarditis should be left alone and the incarcerated heart freed from bony encasement, together with the successful issue of the operations consequent on his suggestion, pointed the way to a wider application of his method. Whether the term "cardiolysis" would be the most appropriate one to designate an operation which had to do, not with loosening the heart from adhesion, but with providing the overgrown organ with more room, and saving it the shock of impact against bone, may be questioned. Thoracostomy is, perhaps, too general a term to indicate its special application to the relief of intra-thoracic pressure exerted upon the heart, or induced by a large and powerfully pulsating organ confined within the thorax, because, as we know, thoracostomy may be employed for various conditions not directly due to cardiac causes. But, qualified by words denoting its special application in particular cases, there seems no insuperable objection to the substantive use of a more general term. I have preferred, therefore, in the following paper, to use the phrase thoracostomy in heart disease, to the more specific cardiolysis of Brauer.

---

[1] Archiv für Klinische Chirurgie, vol. lxxi.

In a paper published in THE LANCET of August 24th, 1907, which, like that on Pericarditis, had also been previously read before the Æsculapian Society, I further emphasised the principle of operative interference to relieve intrathoracic pressure, both when the mere bulk of the organ was the chief feature in the case and when, as in irremoveable mediastinal tumour, the heart was secondarily involved in the neoplastic growth. I referred in that paper, but without giving details, to a case of the latter kind then under my care in which thoracostomy with this object had been performed with benefit, on my suggestion, by my colleague Mr. Ewen C. Stabb. I had not, however, at that time had an opportunity of applying the principle, as I contemplated doing, to the much more important, because more frequently occurring, cases and those more amenable to treatment, in which *size* of heart, with or without adhesions, was the principal feature of the case, but closed the paper with the following words: "The question arises, whether mere bulk is not a disadvantage in these circumstances, and whether, therefore, the justification does not arise for attempting to relieve pressure by the removal of a portion of the ribs and cartilages in the precordia, in obedience to the indications given by the precordial bulging of children, even when it may be assumed that pericardial tethering is absent. I think personally we shall soon be justified in this matter in following John Hunter's advice to Jenner, when the latter was too timid to vaccinate, but thought he might do so with safety. 'Why think,' said Hunter, 'Do it.' I believe we shall also in this matter be able to 'do it' with safety and benefit, both to patients and our own reputation" (p. 508). Since then an operation for the relief of cardiac pain associated with an enlarged heart in a case of double aortic valvular disease under my care has been performed, again by Mr. Stabb, and certainly so far with very encouraging and, indeed, interesting results. Before, however, relating this case more fully, some remarks upon method may be made.

In Brauer's first case, which was operated upon by Petersen of Heidelberg on April 1st, 1902, it is stated that 7, 8, and 9 centimetres respectively of the third, fourth, and fifth ribs were resected. In his second case, operated upon on May 20th, 1902, Dr. Simon is stated to have operated more extensively and removed a portion of the sternum at the same time as ribs which are not specified. This was also done by him in a third case.[2]

I have been privately informed that a fourth case has undergone operation under Professor Brauer's supervision at Marburg, and, as I have stated, Professor Wenckebach of Groningen has published details of a case done on his suggestion by Professor Koch in which "cartilages and parts of the fourth to the seventh ribs" were removed. These were all assumed to be cases in which there had been adhesive pericarditis within and without the sac, and in one of Brauer's cases which died from pneumonia a year after operation pericardial tethering was shown post mortem to exist. Brauer enters at some length into the differential diagnosis of adherent pericardium[3] and revives as a diagnostic sign the value of diastolic impulse, without apparently being aware of the fact that Hope had minutely described the same phenomenon as diagnostic of hypertrophy in his work on "Disease of the Heart" published in 1839 (third edition).

That a correct diagnosis should be arrived at if possible as to the presence of pericardial tethering is, doubtless, important, as it would naturally guide the surgeon as to the method he adopted in operating, and more especially as to whether a portion of the sternum as well as the ribs should be resected. William Mackenzie's suggestion that a portion of the fifth rib-cartilage should first be removed as an exploratory aperture seems valuable. "This removal of the 5th," he remarks, "I regard as the key-stone of the operation. If the intrapleural area is free we have settled in a few minutes the diagnosis of *adherent pericardium*, and on that ground alone I consider the *operation is justifiable*. If we are unable to feel the intrapleural area we know there are adhesions."[4] The presence of such costo-pericardial adhesions, with which in the case of enlarged heart it may be assumed that visceropericardial adhesions are associated, may indicate the removal of a portion of the sternum in addition to the ribs, as practised by Simon in two of Brauer's cases. But, if the clinical phenomena can exclude such adhesion, which, it will be admitted, is often a difficult matter, and, especially in aortic cases, in which the character and direction of hypertrophy usually displace the volume of the left ventricle downwards and to the left, it will probably be found that the best guide in most cases to the amount of thoracostomy necessary will be the area of forcible cardiac impulse, and that the removal of ribs and cartilages without interference with the sternum will fulfil every purpose. It may be unwise to give the heart too much room to act in; it is certainly quite possible to give it too little. With this preface I shall now proceed to relate the clinical history of a case under my care at the Great Northern Central Hospital in which Mr. Stabb performed, at my request, the operation of thoracostomy for cardiac pain associated with an enlarged heart.

A clerk, now 19 years of age and single, was admitted on Dec. 12th, 1907. He first came under my notice on Nov. 22nd, 1901, when he was a schoolboy 13 years of age, and I was physician to out-patients. At that time I made the following note: "Aortic regurgitation. Pain in the left side. Ill some months. No serious illness. 'A little rheumatism' four or five years ago in wrist and knees. No chorea. Heart's apex beat fifth space three inches from mid-sternum. Left ventricular dulness third rib. Right auricular dulness one inch beyond right edge (of sternum). Bruit with thrill at apex, presystolic. Bruit not heard in back. At right base soft aortic diastolic. Carotid pulsation exaggerated. Lungs normal." A year later (Nov. 7th, 1902) I have the note, "Aortic diastolic, but at apex outside nipple line triple rhythm," and on July 1st in the same year, "The chief lesion is aortic regurgitation with a thrill at the apex post-systolic in time and running up to systole." In the interval between this time and December, 1907, I have no personal knowledge of his condition. The disablement which resulted in his admission to hospital at the date mentioned began five months previously. Till then he had gone to work although never strong and suffering a good deal from breathlessness and pain in the chest.

On admission the patient exhibited in an exaggerated degree the well-marked phenomena of aortic valvular disease. The heart's apex beat was in the fifth and sixth spaces about four inches from mid-sternum. The area of cardiac dulness was increased. There was visible pulsation in the intercostal spaces to the left of the sternum, with exaggerated systolic impulse in the carotids and suprasternal space. The cardiac action on palpation was heaving and concussive, with pronounced diastolic thrill over the aortic area. On auscultation a loud and coarse systolic and diastolic bruit was audible at the aortic base and at the apex a rumbling presystolic murmur. His pulse-rate was 88 to 92; its rhythm was regular and its character was of the well-known water-hammer type. The blood pressure, determined by the Riva-Rocci instrument, is noted to have been 125 to 130 millimetres of mercury. Respiration was shallow but there was no evidence of lung disease. His other organs were normal and there was no anasarca or effusion into any of the cavities or cellular textures of the body. The urine was free from albumin.

The patient remained in hospital about five weeks, being discharged on Jan. 18th, 1908. He was treated by rest and cardiac tonics, taking in the first instance strychnine and belladonna with nitrite of amyl to relieve his anginoid pain, and, later, as he made little progress, with strychnine, stropthanthus, and digitalis, which increased the force of systole without relieving his pain. His systolic blood pressure is noted on Jan. 3rd, 1908, as having been 160, and his attacks of pain varied in frequency and intensity but were apparently severe at times. The pain was retrosternal and across the chest but did not radiate into the arms.

---

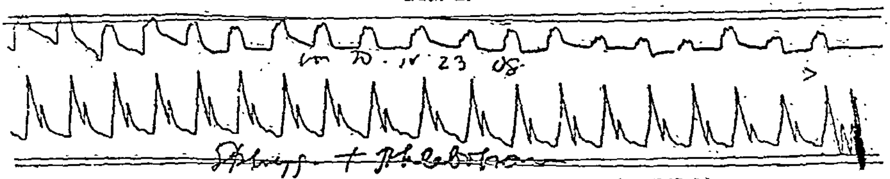
[2] Verhandlungen der Deutschen Gesellschaft für Chirurgie, Band xxxii., p. 133, et seq.

[3] Loc. cit., ii., p. 84.

[4] Loc. cit., p. 495.

There was considerable mobility of the heart's apex beat, which is noted by me as having been 9½ centimetres from mid-sternum in the fifth space when lying on the back, 6½ centimetres from the same point on right decubitus, and 11 centimetres from the tip of the xiphoid process to its beat in the sixth space when lying on the left side. From this I considered it improbable that he had any costo-pericardial adhesion. His condition appeared to be stationary. The attacks of pain, which frequently occurred at night as well as during the day, kept him awake. Although he was able to walk about gently and take his meals regularly he made little progress towards greater activity with comfort but exhibited none of the phenomena of progressive retrograde stasis. Under these circumstances he was discharged from hospital, advised to take cardiac tonics and rest at home, and to report himself from time to time. Before he left I informed his father that I believed thoracostomy might be of service to him but in nowise urged the operation, as I could not speak from experience, direct or indirect, as to its effect in a similar case.

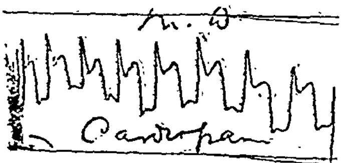
FIG. 1.



Cervical phlebo-arteriogram and radial sphygmogram. (April 23rd.)

Thus the matter rested until April 13th when he was readmitted under my care, having reported himself from time to time without any evidence of recuperation, and suffering more than previously from cardiac pain, over which the inhalations of nitrite of amyl appeared to be losing their power. He was admitted on the understanding that, if he showed no satisfactory improvement, the operation I had suggested should take place. On the 18th I noted that the area of cardiac dulness measured 5½ by 5½ inches, the apex beat was in the sixth space 5 inches from mid-sternum, the area of palpable concussion measured 3 by 4 inches and was covered by the fifth and sixth ribs over an extent of 4 inches including their cartilages, while the other physical signs were as before. The anginoid attacks were often severe but varied in frequency. They occasionally lasted from a quarter to half an hour. On the 24th, some time after an attack had passed off with the use of nitrite of amyl, his pulse-rate is noted as 138, his respirations as 24, and breathing capacity as determined by Lowndes's spirometer as 60 cubic inches. On the 27th it is noted that the patient's "condition (was) unchanged. Fewer anginoid attacks than usual during the last 24 hours. Heart as before: Blood pressure 170 mm. (systolic), 100 mm. (diastolic). Urine normal." His temperature had throughout been normal and the accompanying tracings (Figs. 1 and 2) show the character of his cardiac and arterial pulsations on April 23rd.

FIG. 2.



Cardiogram. (April 23rd.)

My previous experience of such cases had been that relief from cardiac pain was only obtainable by increasing doses of trinitrine, while short intervals of improved cardiac action were not always to be expected, and even if they occurred they did not long postpone the deteriorating signs which heralded the ultimate failure of the heart. I therefore determined to afford the enlarged heart more room to act in, while its power was still good, and asked Mr. Stabb to secure free space for cardiac systole without the incarcerating barrier of hard rib, in the area of thoracic concussion. This he very skilfully did on May 1st in the following manner. A U-shaped incision with its descending limb in the centre of the sternum commenced at the level of the sternal attachment of the third rib. Sweeping round at the level of the seventh rib the ascending limb of the incision was carried to a point corresponding with its commencement. A large flap was thus secured and raised, consisting of superficial textures and muscle down to the ribs. This was turned back and spread between warm moist towels. The fourth and fifth intercostal spaces were next cleared down to pleura and the fifth rib, covered by its periosteum and perichondrium, carefully separated from the underlying pleura and 4½ inches of its length from the sternum outwards, were removed in three pieces. The sixth rib was similarly cleared and 5½ inches of it were removed in one piece, its greater arching allowing more easy detachment without injury to pleura. The internal mammary artery required ligature. A small puncture was made in the pleura while the last portion of the fifth rib was being removed, air being aspirated through it during respiration. The puncture was stitched but was not rendered quite air-tight thereby. The raised flap was then replaced and accurately applied by alternate fishing-gut and horsehair sutures, a drainage-tube being inserted at the lower external angle of the wound and left in position for 24 hours, when it was renewed. After removal of the ribs and display of the underlying movements of the heart the latter appeared to be smooth, rolling, and without adhesion to the extraneous structures exposed. Mr. C. H. C. Visick administered the anæsthetic (chloroform) with the Vernon-Harcourt apparatus, the patient taking it well. Towards the end of the operation strychnine was injected hypodermically, rather as a precautionary than necessary measure. The wound healed by first intention, except at the point of issue of the drainage-tube, where a little leaking continued for a short time.

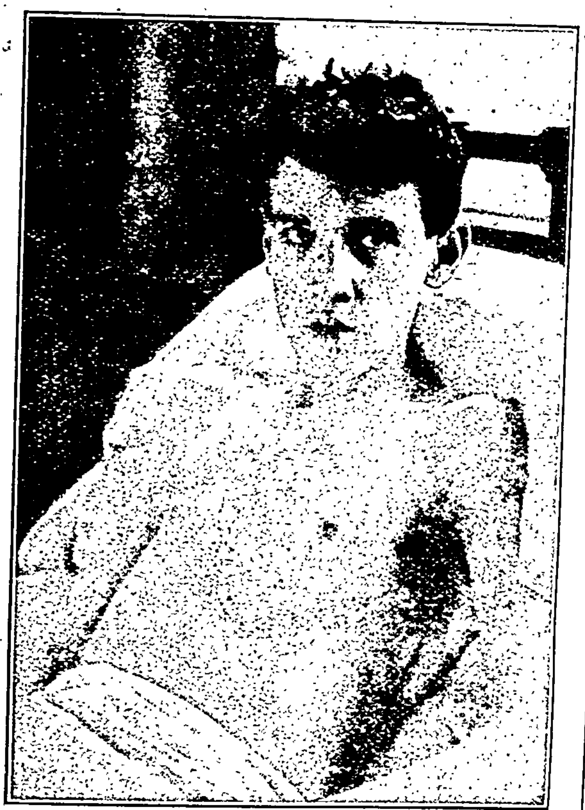
The temperature was slightly raised (99·2°) on the day following the operation and swung between that point and subnormal till May 9th, when it again remained normal or subnormal. The pulse was slightly quickened, running from 108 to 126 until the 9th, when it dropped to 92 to 100, the average pulse before operation having been 80 to 96. It is now 92 to 100. The rate of respiration was most altered, its highest rate being 60 on May 4th and averaging about 40 until the 10th when it dropped to an average 32 till the 17th. It is now 24. The highest pre-operative respiratory rate noted is 36 and the lowest 20. The higher rate recorded was apparently due to shallowness of respiration from pain in the side due to the wound.

The effect of the operation objectively and subjectively has been very satisfactory. The space previously occupied by the fifth and sixth ribs now consists of a soft unresisting cushion formed by the fourth, fifth, and sixth intercostal spaces and the sites of the removed ribs. The palpating hand finds little thoracic concussion, but the powerful throb of cardiac systole into the yielding covering of the heart. The other physical signs remain as before but the exaggeration of carotid and suprasternal pulsation is less marked and the blood pressure registered is from 120 to 130 and at times as low as 115. The apical presystolic rumble is not to be heard. The only palpable thrill is basic (aortic) and diastolic in time. The skin on the præcordia to the left of the sternum below the level of the fourth rib was decidedly diminished in sensibility, doubtless from severance of the fifth and sixth intercostal nerves, but is now recovering sensibility somewhat. The area thus robbed for a time of all sensation (tactile, painful, and temperature) measures about 2 by 4 inches. Finally, before operation the chest capacity as registered by Lowndes's spirometer was 60 cubic inches and on May 18th it was 63. The capacity of two other men, presumably normal, was 120 and

130 cubic inches respectively. Subjectively, the most gratifying result has been that the patient has had a greatly diminished experience of anginoid pain, and even when suffering it affirms that it is decidedly less severe than prior to the operation.

On May 12th Dr. James Mackenzie saw the case with me and asked the patient whether in his opinion the degree of relief he had experienced justified his having undergone the suffering of the operation. This question he emphatically and without hesitation answered in the affirmative. The nurse in charge of the ward during the night has also informed me that the quietude and uninterruptedness of the patient's sleep since the operation are in striking contrast to his broken rest before that event.

FIG. 3.



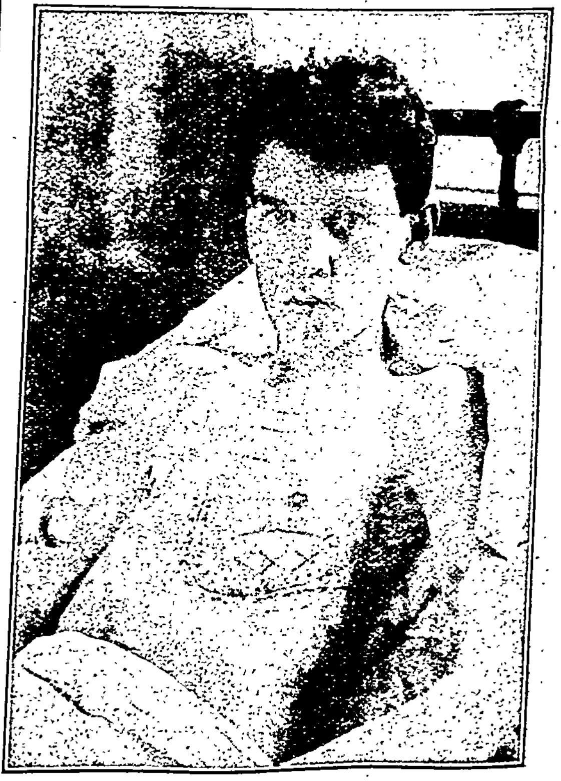
The operation wound healed.

The patient was dismissed from hospital in all respects more comfortable than before operation and perfectly satisfied with his progress on June 6th.[5] Before leaving he was provided with a poroplastic shield to protect the more exposed heart from accidental injury, in imitation of the costal bulging adopted by nature in the young for the same purpose. It transpired in the discussion on Brauer's cases[6] that the enlarged interspaces tended to shrink apparently without undoing the benefit of the operation. Whether this will also prove to be the case in untethered cor bovinum remains to be seen. If this occurs I can scarcely think the change will be beneficial. In the meantime, the perpendicular measurement of the gap in the present instance is seven centimetres.

The accompanying tracings exhibit the character of the cardio-vascular movements at different points and at different dates. (Figs. 5 to 10.)

Remarks.—The normal beat of what is usually assumed to be the "apex" of the heart—that is, the portion of the ventricular heart which comes in momentary contact with the thoracic parietes—occurs at an intercostal space. In the adult this is usually the fifth interspace; in the child frequently the fourth. But whatever the actual position of the beat its brunt is expended on a soft interspace. The finger placed on the rib above and below the pulsating space feels no shock. Under abnormal circumstances the beat may of course be obscured or imperceptible, either when the force of systole is diminished or when there is an abnormal interposition of lung, fat, new growth, or effusion between the heart and the palpating hand. When, however, the heart is increased in size and the force of systole is also in excess of what is normal to the individual, the cardiac apex thrusts, not against a yielding interspace, but against interspace and rib, one or more, according to the size of the systolic ventricle. The finger or hand placed over the heart then feels the concussion of the stroke both against rib or ribs and interspace or interspaces. Again, notwithstanding recent controversies as to the rôle of muscle and nerve in cardiac action, it is admitted that direct muscular stimulation of the eviscerated heart induces contraction, and that in the heart *in situ* nervous impulses have a powerful effect on the organ by way of inhibition, augmentation, and acceleration.

FIG. 4.



The crosses show the enlarged area of the apex beat and the markings show its situation.

Given therefore a large heart powerfully pulsating against hard and resistant structures, what more natural than that the striking and indirectly struck organ should, from time to time, develop a condition of excitation or erythism in excess of what is normal to it, and that such erythism should be associated with increased systolic pressure, augmented by mental causes due to subjective discomfort in various degree, from uneasiness to pain. Such pain, moreover, as has long been known, may find more or less widespread expression in the somatic sensory nerve territory issuing from the segments of the cord related to the organic nerves stimulated on the principles discussed by James Mackenzie[7] and Head.[8] These inconvenient consequences do not follow even the powerful systolic palpitation of a normal heart in a normal situation. It is reasonable to suppose, therefore, that providing the enlarged and powerfully pulsating heart with a proportionately large interspace void of osseous resistance might prove a means of sparing its energy. This was done and a local parietal anæsthesia incidentally produced in the case I have narrated with the ameliorative consequences related.

---

[5] Seen by me on June 25th he stated that he was able to "get about" quite well and that he had not experienced his present condition of thoracic comfort since childhood. He has also increased 5 pounds in weight since leaving hospital.

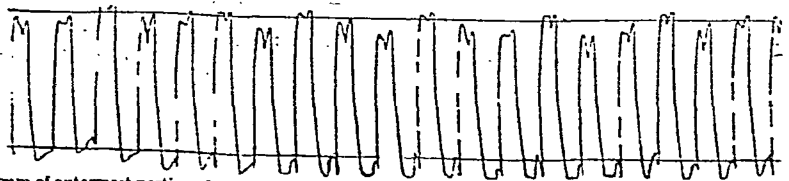
Character of cardiogram at middle portion of enlarged apex beat. Shows respiratory undulation. (May 26th.)

FIG. 10.



Cardiogram of outermost portion of apex beat. Shows large excursions and also respiratory undulations. (May 26th.)

Although I have no desire to argue too widely from a single instance either as to the cause of some anginoid pains in some such cases or as to the value of thoracostomy as an alleviative and conservative measure, the results of the operation subjectively and objectively have been sufficiently gratifying to justify its repetition under similar circumstances. In describing this patient's painful symptoms I have used the term "anginoid," which is difficult to defend. He complains of retro-sternal pain. His pulse and heart quicken and his systolic blood pressure during the attack rises. On the subsidence of pain the pulse-rate falls and with this the systolic pressure falls likewise. The pain is relieved by nitrite of amyl. Under these circumstances the use of the term "angina" would be quite justifiable and it would doubtless be the correct term to use. Why, then, have I not used it? The pain certainly does not radiate far in this case, as it very frequently does in aortic cases, but this fact does not, as we know, invalidate the use of the term angina. I have noted before an abasement of ventricular systolic force during the attacks of angina, or at least interpreted the signs observed as those of abasement from the modification of the cardiac sounds.[9] That modification of sounds I have not observed in this case. The note of the bruit remains the same and becomes not less rough till the pain subsides. The attacks were, prior to operation, very frequent, so frequent that one was tempted to regard some of them as exaggerated by the neurotic disposition of the patient. But this is not justifiable, and on one occasion I roused his indignation by the inquiry as to whether he did not make the most of his sufferings. When we know that he faced so serious an operation after long consideration to gain relief this may be dismissed. The attacks, in truth, were not only like angina but were angina, and my use of the tentative term at any time is indefensible. My reason for continuing to use it after the operation was that the relief produced was much greater than I had anticipated, although not greater than I had hoped, and I hesitated to emphasise the alleviative value of the procedure by employing the more serious term. The fact of relief remains. The cause of relief is more difficult to explain.

When the patient was admitted in December, 1907, the notes of his blood pressure show a variation from 125 to 130 millimetres of mercury during quiescence to 160 when the attacks of angina were more frequent. At my visit on April 27th it registered 170 millimetres and he had at the moment no pain. By this time the operation had been decided upon, and it may have been that emotional causes on this occasion augmented the systolic pressure. The fact remains that since the operation his average systolic brachial blood pressure has been from 120 to 130 millimetres, which appears to be normal for the patient in an anerythetic condition. The operation, therefore, does not seem to have reduced his normal blood pressure, but to have greatly modified the tendency to an erythetic rise of it. This can only be from the removal of some physical as distinguished from emotional incentive to erythism, and that incentive we are surely justified in regarding as the osseous provocation to cardiac stimulation removed by thoracostomy.

We may, therefore, without any undue exercise of the imagination conclude that one cause, at least contributory, to attacks of angina in aortic valvular disease with hypertrophied heart is direct stimulation of the organ by systolic impact against costal resistance, and this may also be regarded as a cause of the premature failure of the hypertrophied heart so frequently observed in practice. It may, of course, be argued that, if this were so, both angina and premature failure would be even more constantly observed than they are in these circumstances. Before this objection can be reasonably met larger experience of the effects of this operation is needed, and as a contribution towards the formation of opinion on the subject I offer this case, which, so far as it goes, certainly supports the conclusion I have indicated, as in any case rational, to avoid a premature and unscientific positivism.

It may also be asked how such a central theory of the production of this type of angina agrees with the accepted notions of peripheral vaso-motor constriction as an incentive to the attacks. While it is not my purpose on the present occasion to discuss this and many other interesting questions on the nature of angina which are raised by the facts I have related, it may be pointed out that the reduction of systolic pressure by the nitrites is also associated with acceleration of the heart and reduction of the cardiac output for each systole, although without diminution of it as a whole. Consequently it is legitimate to urge that a succession of small systoles has not the same concussion influence on the thorax which is induced by the slower and more powerful stroke of the enlarged heart in an erythetic condition, and that the alleviative effect of the nitrites rather supports than opposes my suggested explanation.

In conclusion, I have to thank my house physician, Dr. Woodroffe, for notes of the case, and Mr. Hamilton, the house surgeon, for his care of the patient after operation.

Upper Berkeley-street, W.

MEDICAL MEN CALLED TO THE BAR.—The following medical men have their names on the current call list for Trinity Term: by the Inner Temple, William Henry Whitehouse, M.D. Durh., of Birmingham; and by Lincoln's Inn, Percy John Probyn, M.B., B.S. Lond., Major, R.A.M.C.

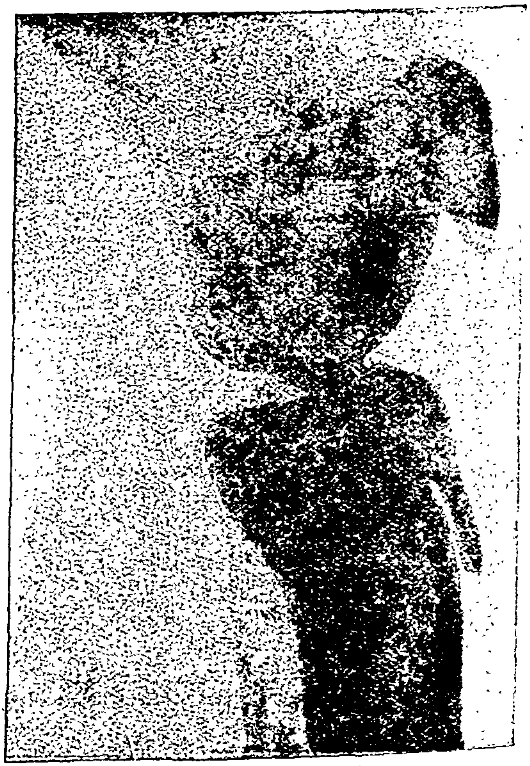
CONCERNING SOME RARE BUT IMPORTANT SURGICAL INJURIES BROUGHT ON BY VIOLENT EXERCISE.

BY PATRIK HAGLUND, M.D.,
DOCENT AT THE KAROLINSKA INSTITUTE, STOCKHOLM; NAVAL SURGEON OF THE SECOND DEGREE.

(*Translated by* OTTO L. HOLST, *M.R.C.S. Eng., L.R.C.P. Lond.*)

THE lesions which form the subject of this paper were exceedingly obscure as to their nature until the introduction of the Roentgen rays made the diagnosis easy. They are most often contracted at the gymnasium, particularly by those who excel, but they occur also as the result of other forms of severe bodily exercises. The most common, and therefore the most important from a practical point of view, is that lesion of the tuberosities of the tibiæ which has received the name of "Schlatter's disease." There is no doubt that all come across cases of it amongst athletic children, most often boys, who have presented a tender spot just where the ligamentum patellæ is attached to the tibial tuberosity, a condition which, although it does not ordinarily necessitate absolute rest in bed, yet is capable of causing much inconvenience and pain and of preventing the sufferer from taking part in games of any kind. Every movement which puts a strain on the ligamentum patellæ gives rise to acute pain. This very unpleasant state of affairs may last a long while, rendering the child more or less an invalid for several months. Strangely enough, it is seldom that the condition can be associated with a specific instance of a particular accident or strain.

FIG. 1.

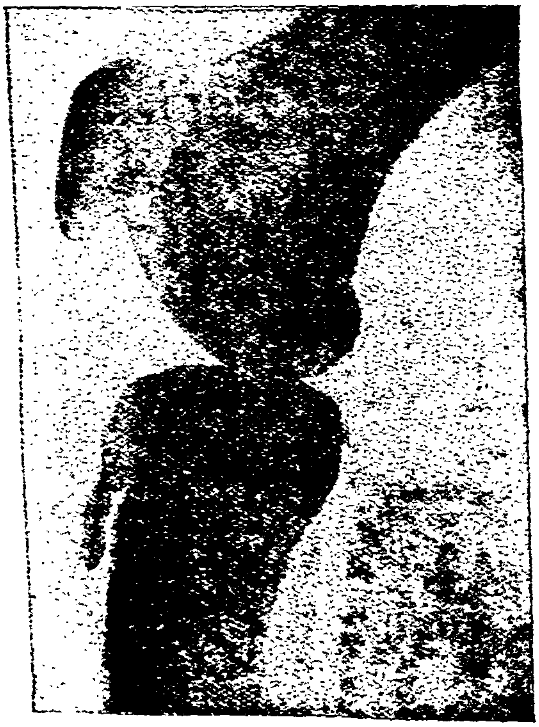


It is only comparatively lately that the disease has been thoroughly understood, thanks to the observations and studies made of it by Schlatter in Germany and Osgood in America. Before that time great uncertainty existed in the minds of surgeons as to its nature, many having suspected tuberculous mischief in the tibia owing to the presence of symptoms pointing to inflammation. Although sometimes operations have been performed, not even then has it been possible to arrive at a correct diagnosis. It is the Roentgen rays that have disclosed to us its true pathology. We knew that the lesion must be caused by something which affected the attachment of the ligamentum patellæ to the tuberosity of the tibia, but as no similar condition was found elsewhere in the human body where tendons, attached to bones, were subjected to strains, one was forced to the conclusion that special circumstances must obtain in this particular position to account for it.

It is well known that the long bones develop from three ossification centres—i.e., one in the shaft and one in each epiphysis. If we examine the upper end of the tibia, we find a very peculiar shape of the ossification centre. Fig. 1 shows a Roentgen picture in profile of the upper end of the tibia in a boy aged 13 years. As cartilage does not prevent the passage of the rays the light interspace between the tibia proper and the tuberosity shows where ossification has not yet taken place. We see how the ossification centre sends down a long projection in front of the upper end of the tibia, which projection, owing to its characteristic appearance, has received the name of "the trunk-like projection of the superior tibial epiphysis." In reality it is not at all trunk-shaped, but broad laterally and flattened antero-posteriorly. This process reaches down to where the ligamentum patellæ is attached and the "point of attachment" is completed by the merging together or union of the bone and the projection which usually takes place at the eighteenth or nineteenth year. Before the twelfth year no trunk-like projection is to be found, but it is about this time that it begins to ossify. As any exertion of the extensors of the knee undoubtedly puts a certain amount of strain on the apex of this projection it is easy to understand how injuries might happen to it. And the lesion with which we are now concerned is just caused by any extra strain brought to bear on this delicate anatomical mechanism.

The traumatic lesion may vary a good deal in its pathological aspect, but it is well to include every form under the generic term of "Schlatter's disease." One may find a bending outward of the trunk-like projection, a partial separation of it from the diaphysis—i.e., fracture in the epiphyseal line, or in still more severe cases a complete separation with the fragments more or less dislocated. In most of the cases a fracture of the projection is found. Figs. 2, 3, 4, and 5 show excellent instances of this condition. Clinically all these varieties resemble one another. They occur always between the twelfth and the nineteenth year; they happen to strong energetic children fond of games; they are more common in boys than in girls and are more often met with in the right leg, as this is the leg which has to bear the brunt in any exertion.

FIG. 2.



It is a curious fact, as has been already remarked, that the patient cannot, as a rule, say when the accident happened.

FIG. 3.
